The first requisite in undertaking the organization of health maintenance-cancer prevention clinics is enlisting the interest and the cooperation of the county medical society and the hospital in which the clinic is to be held. This having been accomplished, details of procedure and function are next to be considered. A usual query, not infrequently so worded that it becomes almost an objection, is "But how can it be done with the present shortage of physicians and nurses?" The answer is, Yankee-fashion, "Can you not find in your institution one physician who is willing to give two hours a week for this service, or two physicians each of whom will give two hours every other week? And a nurse who will give three hours each week (or, similarly, two nurses to alternate in giving three hours weekly)? That will staff your clinic." It will be a small one, surely; but is it not better to serve a few each week—even 2 a week means 100 a year—than not to start at all? And this much may be said: Once a beginning is made, "it shall follow as the night the day" that the proverbial snowball will have started rolling.

In addition to the physician and the nurse, there will be needed a laboratory technician and the services of the x-ray department to take the routine chest film. If equipment for taking small films is available these suffice, since these routine films are for screening purposes only. If anything suspicious is found, the examinee is referred to his physician for further x-ray studies. You notice that the word "examinee" is used rather than the word "patient." This is done advisedly, since these examining centers are not for those who are ill. They are intended for well folk only. No appointment is given to any one who is under treatment unless his physician sends a written request. Neither are appointments made for children.

As to procedures, these may vary from hospital to hospital. The obvious questions are "Where to hold the clinic? What about the laboratory work?" About location: Our five months' experience indicates that it is decidedly advantageous to hold the clinic within easy reach of the x-ray department. This minimizes confusion and loss of time—and, sometimes, loss of examinees. That is literally true. It "did happen here."

The space that appears best adapted to these examinations seems to be the obstetric or gynecology outpatient department. Here there are scales, small tables to be used while taking the histories, and examining tables.

As to the laboratory technician, having her come to the clinic is by far the most satisfactory as well as the most efficient arrangement.

Any details concerning the examining physician's duties would be superfluous here. Suffice it to say that emphasis is placed on care and thoroughness, however time consuming. In the beginning, the schedule is one examinee per hour. As experience and facility increase,

three examinations can be done in the clinic period of two hours. Under unusually favorable circumstances, when the examining physician is especially able, four are completed without difficulty. When the six month period is up and reexaminations begin, I understand that twice as many can be done in a given time. I cannot speak of this from experience, since our clinics are not yet six months old.

As the number of examining physicians increases, it becomes advisable to have one senior examiner, or supervisor, to whom questions can be referred and who assumes responsibility as to technicians, care of charts and disposition of cases.

The hospital which provides the space also arranges for the services of the nurse. She is paid by the hour. She comes sufficiently in advance of the hour of the clinic to see that examining rooms are in order and to check necessary supplies and equipment, such as the gynecologic tray, the otoscope and the laryngeal mirror. She takes temperatures and weights and gets the examinee ready on the table. Her final responsibility is to leave the room in order. Our experience is that one-half hour before and one-half hour after the clinic suffice.

In order to minimize waiting on the part of the examining physician, the examinee is asked to report three quarters of an hour ahead of the hour scheduled. Thus, for a 4 o'clock clinic he is asked to come at 3:15. This allows time for him to go to x-ray, to make his contribution, to register, to report to the laboratory technician, to be weighed. Also he fills in his "information blank" before the examining physician arrives. This mimeographed copy of the face sheet is given him as soon as he arrives, with the request that he fill in all the spaces and do this between times while he is waiting at x-ray or elsewhere. Some one in charge is careful to check over these sheets before the examinee leaves to make sure that all the information that has been requested is given.

CONDUCTING THE CLINICS

Meeting, registering and steering the examinees, and helping them with the face sheets are minor but important details in the functioning of these clinics. In the hands of gray ladies, nurses' aides or other volunteers they are accomplished with tact and skill.

When the examining physician finds anything which requires medical or surgical care, the usual procedure is for him to tell the examinee to get in touch with his physician in ten days or two weeks. One may ask "Why not sooner?" The reason is simple. Laboratory and x-ray reports are subject to delay, especially under present conditions. Accordingly the practice has been adopted of collecting the charts and their laboratory and x-ray findings one week after the examination. Thus charts and findings of examinations made today will be called for and taken to the clinics office one week from today.

In the clinics office the charts are copied and the laboratory and x-ray reports are entered in their proper places. Then, if the examinee is to be referred to his physician, a letter is written and a mimeographed postcard enclosed for the latter's reply. Two carbons are made of each letter. Thus there are two complete sets of each examinee's record. The carbon copy is filed

in the central office, the original, with all report slips attached, in the hospital in which the examination was made.

As to record keeping, a 3 by 5 white index card is made for each examinee. On this are entered the date of the examination, the code letter of the institution in which the examination was made, the name of the examinee's physician and the date on which a letter was sent to him; and space is left for the date on which he reports to us.

Another 3 by 5 index card is typed, this one with the name, address and telephone number of the physician to whom an examinee is referred. The name of the examinee also is given. When reports are received the date, the examinee's name and the substance of the report are entered on the back of the card. Two colors are used for the physician's cards: one is buff, for the usual; the other, aqua, for cases such as dilation and curettement or biopsy, on which an early report is desired.

Before it is filed, each card is flagged to indicate when it is to receive attention. The color of the flag tells us when a reply from a physician is overdue and when an examinee should be notified concerning his next examination.

In addition there is the index file of positive findings. Each chart is carefully checked and the examinee's name entered on the appropriate card or cards. This makes it possible to determine, almost at a glance, the number of cases of, for instance, cervicitis, which have been encountered to date, in which clinic the examinee was seen and the sex.

Nothing has been said concerning appointments. Item one here might be that for some weeks the entire time of one office girl was required to answer the telephone. Within ten days after the announcement that the clinics were to be opened, and before any was in operation, all of them were booked to capacity for six months and there was a considerable waiting list. With appointments made so long in advance, postcard reminders were indicated. These are sent well in advance. The present waiting list is *uncounted* hundreds. There are those who fail to appear for examination but do not cancel the appointment. This is unfortunate, because many are waiting. Therefore, in order to hold an appointment, the examinee is asked to send check or money order for \$2. If this is not received by a specified date, it will be assumed that he does not wish the appointment, and the hour is assigned to some one on the waiting list. The remainder of the contribution is made at the clinic.

So much for the first part of my subject. There are now eight clinics a week in Philadelphia, and plans for more are pending. One was opened in the Falk Clinic in Pittsburgh in early November. Others are in process of organization in various states.

RESULTS OBTAINED

Up to December 1, that is, in just under five months, a total of 919 examinees have been seen, 176 men, 743 women. Of these, 111 men and 493 women were referred to physicians; 3 men and 9 women, who were unable to pay for private medical care, were referred to clinics. Of the 604 physicians who received reports of positive findings, 287 have replied. The replies show that (1) 14 men and 36 women failed to see their

physicians; (2) 4 men and 26 women were referred to specialists by their personal physicians; 7 men and 48 women postponed having treatment; the remainder of these persons were under treatment, or treatment has been completed

Of the first 1,065 examined, there were 15 men and 96 women between 19 and 30, 42 men and 290 women between 31 and 40, 76 men and 285 women between 41 and 50, 48 men and 147 women between 51 and 60, 13 men and 51 women between 61 and 75 and 2 women of 76 or over.

In the 616 who were referred for medical or surgical care, positive findings include 9 malignant lesions: in men, 1 of the colon, 1 of the prostate; in women, 2 of the fundus of the uterus, 1 of the gallbladder, 1 of the cervix, 1 of the peritoneum, 1 of the breast and 1 epithelioma of the skin. Including biopsies requested, there were 48 suspected malignant lesions, 6 in men, 42 in women. Biopsies were requested for 1 man and 28 women. Sixteen dilations and curettages were requested.

Other positive findings include 239 cervical lesions, 177 cardiovascular diseases, 138 skin lesions, 110 hemorrhoids, 77 varicosities, 67 cystoceles, 64 rectoceles, 33 gastrointestinal disturbances, 27 hernias, 20 papillomas, 11 fibromyomas, 8 myomas, 8 lipomas, 3 fibromas of the uterus and 4 unclassified benign tumors. The teeth required attention in 34 cases and the feet in 88.

COMMENT

Perhaps a word should be added as to the christening of these examining centers. The name used is admittedly heavy and cumbersome. But I submit that if their name is to indicate their purpose it can't be short. Try a few alternatives, such as "periodic health examinations with emphasis on conditions which may lead to cancer," or "diagnostic clinics with emphasis on cancer prevention." You can go into solitary confinement and play around with words and synonyms and rearrangements for a week and still come up with a mouthful. If any one can do otherwise, more power to him.

It may be that you have heard echoes of a debate as to terminology—possibly you've heard the terms "cancer prevention" and "cancer detection" used and abused, cussed and discussed. Far be it from me to enter such a controversy; but it may be noted (1) that we don't want to wait until a cancer is there to be detected—we want to catch its forerunner, as far as this may be possible, and (2) that it is generally agreed (as was mentioned in this city a few days ago) that removing keratoses from 100 individuals means that those 100 will not have cancers in the keratotic areas. Similarly with certain nevi.

In my opening sentence reference was made to the desirability of the interest and cooperation of the county medical society and the hospital which provides space for the clinics. These are of the essence. And I cannot close without a word of appreciation to the Philadelphia County Medical Society and the several hospitals concerned in the launching of this vital public health service. Such success as it has enjoyed is due in no small measure to their enthusiastic support and superb cooperation.

Lincoln-Liberty Building, Philadelphia 7.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary

SUCCINCHLORIMIDE.—N-chlorosuccinimide.—The chlorinated imide of succinic acid— $C_4H_4O_2NCl$ —M. W. 133.54. Succinchlorimide yields not less than 25.0 per cent nor more than 26.6 per cent of active chlorine.

Actions and Uses.—Succinchlorimide is proposed for use in disinfection of water. Data were submitted showing that succinchlorimide will disinfect water containing *Escherichia coli*, *Eberthella typhi*, *Salmonella paratyphi* A and B, *Vibrio cholerae* and *Shigella dysenteriae* within twenty minutes in dilution of 11.6 parts per million (approximately 1:100,000).

Dosage.—For the disinfection of water, 11.6 mg of succinchlorimide per liter.

Tests and Standards—

Succinchlorimide occurs as a white to yellowish white powder possessing a relatively strong odor of chlorine. It is sparingly soluble in benzene and in chloroform, slightly soluble in ether. Its solubility in water approximates 1.6 Gm per hundred cubic centimeters at 25°C. The pH of a saturated aqueous solution of succinchlorimide is about 4.0. Succinchlorimide begins to sublime at about 127°C and melts at from 147 to 150°C.

Although it appears to be relatively stable toward light and air at ordinary temperatures, succinchlorimide should be packaged in air tight, light resistant containers.

Place a few crystals of succinchlorimide in a test tube and add 2 cc of sodium iodide solution and 10 cc of chloroform. A purple color develops in the chloroform layer.

To 5 cc of a saturated aqueous solution of succinchlorimide, acidified with diluted sulfuric acid, add 5 cc of ethyl acetate and 1.0 cc of sodium thiosulfate solution. Shake the mixture vigorously for a short time and transfer the layer of ethyl acetate to a watch glass, evaporate the ethyl acetate slowly to dryness and collect the resulting white residue. The succinimide obtained melts at 124°C. Heat a small amount of the succinimide obtained with ten to twenty times its amount of zinc dust contained in a test tube. When distillation begins, place a pine splint which has been soaked for thirty seconds in hydrochloric acid in the fumes. A red color develops in the splint.

Ignite about 2.0 Gm of succinchlorimide, accurately weighed until it is charred. Moisten the residue, after cooling with a few drops of sulfuric acid and reignite to constant weight. The residue is not more than 0.15 per cent.

Dissolve about 0.15 Gm of succinchlorimide, accurately weighed, in 100 cc of water contained in an iodine flask. Add 3 Gm of potassium iodide and 10 cc of dilute sulfuric acid. Stopper the flask, seal the stopper with a known amount of tenth normal sodium thiosulfate solution and allow to stand five minutes with occasional swirling. Loosen the stopper, allowing the thiosulfate solution to run into the iodine flask, wash the stopper and neck of the flask with 5 cc of carbon tetrachloride followed by water, and titrate with more tenth normal sodium thiosulfate to the disappearance of color in the carbon tetrachloride layer. As the end point is approached it is necessary to stopper the flask and shake it frequently and vigorously, with care to avoid loss of contents. Each cubic centimeter of tenth normal sodium thiosulfate is equivalent to 0.001773 Gm of active chlorine. The active chlorine content of succinchlorimide is not less than 25.0 per cent nor more than 26.6 per cent.

NATIONAL ANILINE DIVISION, ALLIED CHEMICAL & DYE CORP., NEW YORK

Succinchlorimide: Bulk.

GLOBIN INSULIN WITH ZINC (See Supplement to New and Nonofficial Remedies, 1944, p. 31)

The following additional dosage form has been accepted
BURROUGHS WELLCOME & CO., INC., NEW YORK.

Globin Insulin with Zinc: 10 cc. Each cubic centimeter contains 40 units; 0.18 per cent W/V cresol as preservative.

SATURDAY, SEPTEMBER 22, 1945

OFFICIAL CALL

To the Officers, Fellows and Members of the
American Medical Association:

The Annual Session of the House of Delegates of the American Medical Association will be held in Chicago, Illinois, from Monday, December 3, to Thursday, December 6, 1945.

Herman L. Kretschmer, President.

H. H. Shoulders,

Speaker, House of Delegates.

Attest:

Olin West, Secretary,

Chicago, September 14, 1945.

SYRINGE TRANSMITTED HEPATITIS

The occurrence of jaundice in American and British troops and in the natives of Brazil following administration of yellow fever vaccine was a serious problem early in the war. Elimination of the human serum in the preparation of the vaccine prevented such jaundice, which was demonstrated to be of hepatic and not of hemolytic origin. The hepatitis or the syndrome of "homologous serum jaundice" presented as a constant feature the long interval between the injection of a human blood product and the appearance of jaundice. The incubation period is sixty to ninety days. The nature of the icterogenic factor in the human serum has not been determined, although many believe it to be a virus.

Bigger¹ has concluded that jaundice in syphilitic patients who receive intravenous arsenicals is due to transmission of a virus from patient to patient and not to the toxic effect of the arsenical on the liver. MacCallum² clearly demonstrated that hepatitis in syphilitic patients under arsenical treatment results from the

transmission of an infective agent on syringes and needles. Dible, McMichael and Sherlock³ did not find histologic criteria for the differentiation of the lesions resulting from epidemic hepatitis, arsenotherapy and serum inoculations in their aspiration biopsy studies of 56 cases of acute hepatitis. Sheehan⁴ observed that epidemic hepatitis can be transmitted from one patient to another by syringes used for collecting blood. Droller⁵ reported the occurrence of hepatitis among patients in a diabetic clinic as the result of collecting blood in syringes which were not boiled. The accumulation of recent data suggests that any syringe used for taking blood may be potentially icterogenic.

The data with regard to syringe transmitted infection are in accord with what is known about hepatitis transmitted by the injection of yellow fever vaccine containing dried human plasma, of measles or mumps convalescent serum and of blood in transfusions. In all cases injection of presumably infected human blood or plasma has been followed by cases of hepatitis two or four months later. Darmady and Hardwick⁶ found among 182 consecutive patients with jaundice admitted to their hospital that 34 had received intravenous or intramuscular injections within the previous two hundred days. These authors stress two points in the prophylaxis of syringe hepatitis: First, the quantity of icterogenic principle involved may be extremely small and can be harbored in any syringe. Thus Bradley, Loutit and Maunsell⁷ produced jaundice in human subjects by the administration of as little as 0.1 cc. of homologous serum. Secondly, this agent is heat resistant and is not killed by the ordinary methods of sterilization.

All syringes and apparatus used for the intraveous or intramuscular injection of human subjects should be sterilized by dry heat. To secure blood for laboratory purposes a syringe is unnecessary, provided a tourniquet is used. Enough blood can be withdrawn from the vein by the use of a wide bore needle alone, allowing the blood to drip into the appropriate tube. Mendelssohn and Witts⁸ have demonstrated that, when blood is taken from a vein with a syringe by the orthodox technic, some of the blood is sucked back into the vein when the tourniquet is released. If, therefore, the syringe is not sterile, the patient is exposed to infection.

A committee of experts appointed by the Medical Research Council (England) under the chairmanship of Professor G. S. Wilson made a number of recommendations on the subject of proper sterilization of syringes.

2. MacCallum, F. O., and Bauer, D. J.: Homologous Serum Jaundice, *Lancet* 1: 622 (May 13) 1944.

They point out that intravenous injection of drugs will usually contaminate the syringe with the patient's blood, as Mendelssohn and Witts have demonstrated; that any one with acute or recent respiratory infection should wear a mask during manipulation of syringes. Much of the trouble with syringes comes from failure to clean them properly before resterilization. Thorough cleansing is particularly needed when the syringe has been used to aspirate blood or pus. While sterilization in the hot air oven (160 C. for one hour) or in the autoclave is best, sterilization by boiling must often be adopted and is effective against all but highly resistant sporing organisms. Chemical disinfection of syringes has many disadvantages and the only permissible disinfectant is 70 to 75 per cent alcohol. Even then, only all-glass syringes disassembled and immersed under the alcohol for five minutes can be guaranteed to be free of vegetative pathogens. This method of sterilization is therefore justified only for such procedures as insulin injections, in which heating sterilization is impracticable.

The accumulation of data regarding the occurrence of homologous serum jaundice suggests the necessity for revision of the existing injection technics particularly as regards sterilization of syringes and needles.

PREVENTION OF FROSTBITE GANGRENE

Using their new fluorescein test, Lange and his associates¹ of New York Medical College have added new basic facts to the pathologic physiology of frostbite. In this test small amounts of fluorescein are injected intravenously, and the migration of the material through the blood stream and into interstitial tissue spaces is followed under ultraviolet light. Applying these new technics, the New York clinicians have suggested a promising new method for the prevention of post-frostbite gangrene.

In Lange's initial experiments, 6 rabbits were depilated on the abdomen and exposed to cold by applying the bottom of a small beaker filled with solidified carbon dioxide for periods varying from five to ninety minutes. Under this exposure the local area freezes solid and thaws after intervals varying from fifteen to twenty-five minutes, depending on the length of the exposure. For periods varying from thirty to one hundred and twenty minutes following such refrigeration, fluorescein does not appear in the exposed area, indicating a severe initial spasm of the blood vessels. This is followed by gradual vasodilatation, fluorescein appearing in the exposed area. Diffusion into the surrounding tissues is soon many times greater than in nonexposed skin, giving the picture of local hyperfluorescence. This period is characterized also by swelling of the exposed tissues.

Eight to fourteen hours after exposure, a repeat fluorescein injection shows that the exposed spot is again relatively nonfluorescent, indicating a terminal interference with the local circulation. Biopsies at this period show a clumping of the red blood cells in the smaller blood vessels, confirming the "silting" or "sludge formation" previously described by Scandinavian² and British³ investigators. This clumping does not represent true thrombus formation since the clumped erythrocytes are readily washed out by a simple saline injection. After approximately seventy-two hours true or organized thrombi are formed, at which time the entire area becomes nonfluorescent and gangrenous.

If this terminal organized thrombosis could be prevented, the seriousness of frostbite gangrene could no doubt be reduced. Lange attempted to accomplish this by heparinization. Groups of rabbits were subjected to experimental frostbite of varying degrees of intensity. Within four hours, half of the members of each group were heparinized. In a typical group of 22 rabbits, one hind leg of each animal was protected by a thin boot of rubber and exposed to an alcohol-solidified carbon dioxide bath ($-20^{\circ}\text{C}.$) for a period of from forty-five to ninety minutes. Eleven of the exposed animals were then heparinized. Nine of these recovered without signs of gangrene; only 2 of them developed slight surface lesions. All of the untreated controls lost their legs by complete gangrene, including the bone.

The practical applicability of heparin therapy to human medicine was tested on volunteers from the Jewish Hospital of Brooklyn. Experimental frostbite was produced by applying for ten minutes to the upper part of the arm the bottom of a porcelain crucible filled with solidified carbon dioxide. The heparinization was started immediately, 1 volunteer of each group being untreated to serve as a control. All of the treated persons recovered without deep injury.

Thus far only 1 patient has been treated according to the new method. This man had been lying in the street at subfreezing temperature for at least fourteen hours. On admission his hands and the lower part of his legs were ice cold and remained so for five hours after admission. He was heparinized for five days by the intravenous route, the clotting time being held at between thirty and sixty minutes. He developed considerable blistering, especially on the hands, but escaped any permanent loss of tissue. Previous experience with similar cases had suggested that without heparinization there probably would have been some loss of the extremities.

Experiments are now in progress to perfect the method of heparinization and to determine the longest interval between exposure and start of therapy that will still be effective.

FUNGICIDAL TITER OF CLAVACIN

In 1942 Waksman and his associates¹ of the New Jersey Agricultural Experiment Station described two new antibiotics, each of which was superior to penicillin in its bacteriostatic action on gram positive bacteria in vitro. One of these they named "clavacin" after the organism from which it was isolated (*Aspergillus clavatus*). Clavacin was particularly interesting since it was also bactericidal in high dilution against gram negative micro-organisms and bacteriostatic for certain common fungi. Since then clavacin has been isolated in crystalline form.

On first view, clavacin is of little clinical interest since it is highly toxic on intravenous or intramuscular injection into animals. Herrick² of the Hygienic Laboratory, University of Michigan, however, calls attention to the fact that many antibiotics are toxic on parenteral injection but most of them are nontoxic when given orally or applied externally. Since most fungous diseases are both local and superficial in character, the effects of clavacin on pathogenic fungi should be of clinical interest. Three typical pathogenic fungi were therefore tested by him: *Monilia albicans* (thrush), *Oidium asteroides* (blastomycetic dermatitis) and *Trichophyton gypseum* (epidermophytosis).

To test the fungistatic action of clavacin, serial dilutions of the crystalline product were made in liquid culture medium, and 25 cc. samples of each dilution inoculated with one drop of a heavy suspension of the organism to be tested. At the end of four to seven days' incubation, turbidity readings showed that growth of *T. gypseum* was distinctly inhibited by a 1:100,000 dilution of clavacin and totally inhibited by a 1:10,000 dilution. The two other organisms were slightly more resistant, requiring from two to four times these concentrations for similar effects.

To determine the fungicidal titers the test organisms were similarly exposed to higher concentrations of clavacin and viability tests made at stated intervals, washed centrifuge samples of the exposed organisms being used to inoculate subcultures. Failure of the subcultures to grow showed that all three test organisms were killed within fifteen minutes to one hour by 1 per cent clavacin and by the end of three hours by 0.5 per cent clavacin. The most susceptible organism (*T. gypseum*) was also killed within five hours by 0.1 per cent clavacin.

Since 0.5 per cent clavacin is lethal for all pathogenic fungi thus far tested, clavacin in this concentration should be of research interest in the treatment of local fungous infections of the skin and exposed mucous surfaces. Less concentrated solutions might be of prophylactic interest. Clinical tests, however, have not yet been reported.

Current Comment

THE DISTINGUISHED SERVICE MEDAL

The Distinguished Service Medal of the American Medical Association will be presented for the eighth time at a meeting to be held during the regular session of the House of Delegates at the Palmer House in Chicago December 3 to 6. The first presentation of this medal was made in 1938 to Dr. Rudolph Matas of New Orleans. It has subsequently been awarded to Dr. James B. Herrick of Chicago in 1939, to Dr. Chevalier Jackson of Philadelphia in 1940, to Dr. James Ewing of New York in 1941, to Dr. Ludvig Hektoen of Chicago in 1942, to Dr. Elliott P. Joslin of Boston in 1943 and to Dr. George Dock of Pasadena, Calif., in 1944. This award is recognized as one of the most distinguished honors within the gift of the American Medical Association. Any Fellow of the Association may submit nominations, which should be sent, together with a record of the scientific services of the nominees, to the chairman of the Committee on Distinguished Service Award, Dr. A. A. Walker, 2250 Highland Avenue, Birmingham, Ala., or to the Secretary of the Association at 535 North Dearborn Street, Chicago. Of all nominations received by the Committee, five are submitted to the Board of Trustees of the Association, from which the Board selects three to be submitted to the House of Delegates at its first meeting at the time of its regular session. Immediately on submission of the nominations by the Board of Trustees, the House of Delegates by official vote selects the recipient of the honor, to whom the Distinguished Service Medal is presented at the meeting at which the President-Elect is installed as President, which usually is on Tuesday evening of the week of an annual session. An extensive list of distinguished physicians nominated for this award will enable the Committee, the Board of Trustees and the House of Delegates, all of whom participate in the selection, to determine for 1945 a recipient of distinction whose nomination will reflect favorably on himself and on the Association.

A LABOR LEADER DISCUSSES COMPULSORY SICKNESS INSURANCE

Times change, and the points of view of men change with time—but there are fundamental principles of human thinking and living that are eternal verities. On Dec. 5, 1916 a conference on social insurance was held in Washington to consider such problems as unemployment insurance, old age insurance and sickness insurance. Samuel Gompers, then president of the American Federation of Labor, speaking with deep feeling from some simple memoranda, warned organized labor of the threat inherent in the collectivist philosophy by which some leaders of labor are being seduced today. His address might well have been written as of today. Elsewhere in this issue (page 299) the address is published in full. Every leader of labor in the United States, every worker, every physician should read it and heed it. It is a cry of warning to those who would destroy the American democracy.

MEDICINE AND THE WAR

MEDICAL DEMOBILIZATION

NAVY

In the discharge of its obligation to the civilian public the Navy Department desires to accomplish as rapidly as possible the release of physicians, dentists, nurses and other officers and enlisted personnel of the Naval Reserve trained in medical fields. It is obvious that during the next few months they will be needed at almost full strength for the care, evacuation and disposition of the wounded and sick still coming from overseas and also in connection with general demobilization.

The transportation of wounded require full staffing at the point of departure, en route to the medical centers in the United States and within the naval hospitals and dispensaries of the continental United States. It should be remembered that the peak hospital census in military establishments in this country following V-E day was not reached until July 1.

The medical corps will perform a vital function over the next year or eighteen months in the separation process promised for over two and a half million men. Every man and woman returned to civilian life must be given a physical examination to include a chest x-ray, blood tests and any other testing individually indicated.

The necessary lag in medical demobilization behind general demobilization will be kept at an absolute minimum, and every effort will be made to respond at the earliest moment to the special needs of medical schools, teaching hospitals and individual and community hardship cases.

Effective September 15, therefore, the higher critical score for medical corps release is necessary, as announced in ALNAV 252. This critical score requires a total of 60 points on the following basis:

- ½ point for each year of age, computed to nearest birthday.
- ½ point for each month of active duty from Sept. 1, 1939.
- ¼ point additional for each month of active duty outside the United States since Sept. 1, 1939 (effective Sept. 15, 1945).
- 10 points for a state of dependency existing as of Aug. 15, 1945.

On this basis it is determined that 1,128 medical officers will be eligible for release by September 15, 190 additional by November 1, 137 additional by December 1 and 223 additional by January 1, or a total of 1,678. Thereafter it is expected that critical scores for release will be lowered by degrees in order to carry out the present plan to separate a total of 8,000 medical officers by Sept. 1, 1946.

Many medical officers in the Reserve desire opportunities for "refresher" training before returning to civilian practice. Assignments to duty in United States naval hospitals afford one means of supplying such training, and the average period of time allotted for this specific purpose will probably be about three months.

Officers who elect to continue on active duty for a "refresher" period after becoming eligible for release under the point system may do so if they so request. The request may state that it is understood that this continuance on active duty after eligibility for release is for the purpose of obtaining an assignment in a specific type of service in a naval hospital for "refresher" training.

In a limited number of instances such assignments may be available and possible before the full 60 points of eligibility for release have been reached, but this "refresher" training by hospital assignments may retain an officer beyond the date when his point eligibility for release becomes effective. Periods of assignments of this type, constituting active duty in any United States naval hospital officially approved for graduate or residency type training, may be submitted for credits before the American colleges and the American boards with every likelihood of acceptance.

Plans are projected for the peacetime utilization of medical officers of the Reserve on inactive duty as consultants, lecturers

or otherwise in naval hospitals near their place of residence. Additional plans are under consideration in which the active assistance of reserve officers is desired and to be enlisted whereby junior medical officers in the regular Navy undergoing graduate training in United States naval hospitals may seek and obtain one year residency appointments in the foremost civilian institutions for the rounding out of their specialty training.

The graduate educational program of the medical corps of the regular Navy, already in full swing, and its peacetime administration offer inducement to medical officers of the Reserve to transfer to the regular Navy. This, it is hoped, may be sought by many.

The continued and active interest of our many reserve officers in the constant advancement of the medical corps of the United States Navy and in its aims is desired and solicited by the Bureau of Medicine and Surgery of the United States Navy.

ARMY

Following the termination of hostilities in Europe, the Surgeon General sought to build up maximum medical support in the Pacific for projected operations against Japan and simultaneously to provide an orderly system for the release of Medical Department officers after insuring that requirements would be met for the Army of Occupation in Europe and for hospitals in the United States with their large numbers of sick and wounded.

The early advent of V-J day necessitated radical changes in the Surgeon General's planning. The Pacific changed from a deficit theater in need of thousands of additional personnel for full-scale military operations to a surplus theater which had available for return large numbers of Medical Department personnel to the United States just as soon as the occupation of Japan had been completed. Improvement in the overall transportation situation likewise made it possible to accelerate the return of troops from the European and Mediterranean theaters, which presaged the more rapid return and separation of Medical Department personnel.

The cessation of hostilities in the Pacific also had important bearing on the large general and convalescent hospitals in the United States to which the more seriously sick and wounded are returned for definitive care. Except for small numbers of battle casualties now scattered through Pacific hospitals whose early return to the United States is a prime objective, no additional battle casualties will be evacuated and the patient flow from overseas will be limited to individuals with serious diseases or nonbattle injuries. This foreshadowed an early shrinkage in the general and convalescent hospitals at home.

The rapid demobilization of the Army during the coming months will necessitate the use of almost 2,000 Medical Corps officers at separation centers for final examinations. In addition, the large number of limited service personnel whose separation will be effected under the demobilization plan will further increase the requirement for Medical Corps officers for medical processing work.

Under the V-E plan, which was published in full in THE JOURNAL August 11, page 1104, it was necessary to establish adjusted service ratings for separation as high as 120 for scarce Medical Corps specialists and 100 for nonscarce Medical Corps officers. These high adjusted service ratings reflected the fact that the Army was in a position to release Medical Department personnel only very slowly as long as the war in the Pacific continued and large numbers of battle casualties in the United States Army hospitals had not yet completed their treatment.

The worldwide distribution of Medical Corps officers at the beginning of September is estimated as follows: approxi-

mately 22,000 overseas, 11,000 in the European theater and 9,000 in the Pacific and the Asiatic mainland; the remainder overseas are in other bases such as Newfoundland, the Middle East, on hospital ships, and in dispensaries of the Air Transport Com-

TABLE 1.—Criteria for Separation

Corps	Adjusted Service Ratings	Age	Length of Service
Medical Corps.....	80	45	Prior to Pearl Harbor*
Dental Corps.....	80	45	Prior to Pearl Harbor
Veterinary Corps.....	80	42	Prior to 1941
Sanitary Corps.....	70	42	Prior to Pearl Harbor
Medical Administrative Corps.....	70	42	Prior to Pearl Harbor
Army Nurse Corps †.....	35	35	
Medical Department Dietitians †.....	40	40	
Physical therapists †.....	40	40	

* Except grades A, B and C of ophthalmologists and otolaryngologists, orthopedic surgeons and medical laboratory officers, all grades of neuropsychiatrists and plastic surgeons (prior to Jan. 1, 1911).

† In addition, married, dependents under 14.

mand. There are about 16,000 in the United States, excluding 3,000 who are patients in hospitals and newly commissioned officers in training status. Another 4,000 were in transit to the Pacific as of V-J day; this group now becomes immediately available for separation or as replacements for high point individuals who can be separated immediately.

Under the V-E plan, almost 1,500 Medical Corps officers have been separated. The Surgeon General testified on August 31 for the Military Affairs Committee of the House of Representatives that he planned to separate a total of 13,000 Medical Corps officers, 25,000 nurses and 3,500 dentists by the end of this year.

It is estimated that about 6,000 Medical Corps officers will be returned from Europe for separation and that an equivalent number can be released from personnel now in the United States. Surplus medical personnel will be returned from the Pacific as expeditiously as possible. A commission is now on its way to the Pacific to determine the exact number of surplus personnel. As already stated, 1,500 doctors have already been

released under the V-E plan, and it now appears that the 13,000 estimate presented by the Surgeon General to Congress may be exceeded.

The original criteria for the release of Medical Corps officers were geared to adjusted service ratings and age. On the basis of both military and civilian reactions, a third factor, length of service, has been added.

Table 1 summarizes the criteria for separation, any one of which is basis for relief from active military service.

Despite the cessation of hostilities, a limited number of Medical Department personnel must still be sent from the United States to overseas theaters to permit the return of high score individuals for separation. The criteria presented in table 2 have been established to govern the selection of personnel for overseas service, except for volunteers. Individuals to go overseas must have a point score below that listed in the table or be below the age therein shown.

The separation criteria now in effect will have to be revised on or before the end of this year. Present plans contemplate the lowering of criteria during the first half of 1946, which will include a provision for length of service as a basis for separation

TABLE 2.—Criteria Governing Selection for Overseas Service

Corps	Adjusted Service Ratings	Age
Medical Corps.....	45	40
Dental Corps.....	45	40
Sanitary Corps.....	45	35
Veterinary Corps.....	30	35
Medical Administrative Corps.....	30	35
Army Nurse Corps.....	12	30
Medical Department Dietitians, Physical Therapists.....	18	30

of officers who came on active duty after Pearl Harbor. On the basis of a 2.5 million army, the Surgeon General will be able to release from V-E strength approximately 30,000 Medical Corps officers and 10,000 dentists and more than 40,000 nurses.

ARMY

NEW SCHOOL OF PREVENTIVE MEDICINE

A school of preventive medicine, the first of its kind in the Army, has been organized at Army Headquarters, Middle Pacific, Fort Shafter, T. H., and will leave shortly for Manila for duty under General of the Army Douglas MacArthur. The purpose of the school, which is composed of a selected group of 14 officers and 28 enlisted men, is to train army personnel in the most efficient methods of protecting troops from disease. The staff includes specialists in epidemiology, sanitation, malaria, biostatistics, mammology, nutrition, entomology, parasitology and industrial hygiene.

Three regular courses and a special course will be taught. A four weeks course for Medical Department officers will provide instruction in epidemiology, control of insect borne disease, sanitary engineering, venereal disease control, nutrition, industrial hygiene, environmental sanitation and rodent control. It is planned that twenty-five officers at a time will be enrolled in this course. The line officers' course, lasting two weeks and accommodating twenty students, will teach battlefield hygiene, including insect and rodent control, water discipline, garbage disposal and control of other factors which could cause epidemics among troops. A similar course of the same length and student capacity is designed for noncommissioned officers.

Under certain circumstances a special team from the school will be dispatched to the location of units to conduct one or more of the courses, varying in length and number of students according to the time available and the needs of the unit. Sufficient supplies and equipment can be carried by the group to sustain itself without the necessity of becoming attached to any hospital for food and quarters.

ARMY AWARDS AND COMMENDATIONS

Captain Ludwig J. Pyrttek

The Bronze Star was recently awarded to Capt. Ludwig J. Pyrttek, formerly of Hartford, Conn., "for meritorious service in connection with military operations against an enemy of the United States from July 11, 1944 to April 24, 1945. Captain Pyrttek," the citation continued, "as medical officer in a clearing company for an infantry division and later in collecting company for an infantry regiment during this period has displayed extraordinary ability, tireless energy, understanding sympathy and deep devotion to duty. Handling the patients coming under his care with a superior degree of professional skill, he has been responsible for the saving of many lives. His constant consideration of the welfare and comfort of the wounded and the efficient and unselfish manner in which he has contributed to the successful operation of these two organizations reflect credit on his character and ability as an officer and on the Medical Corps of the Army." Dr. Pyrttek graduated from Rush Medical College, Chicago, in 1942 and entered the service Aug. 13, 1943.

Lieutenant Colonel Isidore A. Feder

The Legion of Merit was recently awarded to Lieut. Col. Isidore A. Feder, formerly of Brooklyn. The citation accompanying the award read "For exceptionally meritorious conduct in the performance of outstanding service, as chief of medical service of the 45th Evacuation Hospital from Aug. 2, 1944 to May 10, 1945. Lieutenant Colonel Feder made many recommendations on the treatment of battle casualties which have been adopted throughout the Ninth United States Army. The skill and dispatch with which he organized a tuberculosis service in Buchenwald at the notorious German concentration camp

rapidly relieved a critical epidemic risk at that institution. The judgment and devotion to duty displayed by Lieutenant Colonel Feder reflect highest credit on himself and on the armed forces of the United States." Dr. Feder graduated from Tufts College Medical School, Boston, in 1927 and entered the service Aug. 12, 1942. Dr. Feder is also the recipient of the Bronze Star (*THE JOURNAL*, July 7, 1945, p. 738).

Major Luther C. Heidger

The Bronze Star was posthumously awarded to Major Luther C. Heidger, formerly of Stratford, Conn., for "service from March 2 to Sept. 7, 1944 at Lasang, Davao, Philippine Islands, and aboard a prison ship. As senior medical officer of a prisoner of war camp and aboard an enemy prison ship he performed his work exceptionally well even though seriously handicapped by lack of medicine and equipment. Aboard the ship he requested the enemy to furnish more air and water for the prisoners and used every persuasive means possible to obtain the bare essentials of life for his men. He devoted his entire attention to furnishing medical aid and by his understanding and encouragement he inspired the men and gave them hope. He sacrificed his life in the course of his patient devotion to duty." Dr. Heidger graduated from the University of Vermont College of Medicine, Burlington, in 1921 and entered the service Sept. 12, 1941.

Captain Charles F. Lewis

Capt. Charles F. Lewis, formerly of Oakland, Calif., was recently awarded the Bronze Star. "While a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945," the citation read, "he performed outstanding services as ward surgeon in a general hospital. With improvised, makeshift equipment and depleted medical supplies, he labored against great odds and on a starvation diet. In addition to his medical duties he served as commanding officer of the medical detachment, a task which required day and night duty under extremely hazardous conditions. His excellent leadership, his cheerful attitude and his unflinching courage and devotion to duty were a great inspiration to the entire prison camp." Dr. Lewis graduated from the University of Louisville School of Medicine in 1940 and entered the service July 12, 1941.

Lieutenant Colonel John Groopman

The Soldier's Medal was recently awarded to Lieut. Col. John Groopman, formerly of New York, "for heroism in the Burma-China-India theater of operations. Colonel Groopman voluntarily risked his life on the night of July 8, 1944 while serving as medical officer of the day at an air base in China." The citation stated further that "Groopman, without regard for personal safety, ran to a burning bomber plane, loaded with gasoline, bombs and ammunition, that had crashed at the end of a runway and attempted to extricate its crew. He was warned that the bombs and ammunition might explode at any moment and indeed ammunition did go off from time to time, but he insisted on crawling close to the burning plane in an effort to render aid." Dr. Groopman graduated from New York University College of Medicine, New York, in 1932 and entered the service Oct. 5, 1940.

Captain Floyd M. Burgeson

The Bronze Star was recently awarded to Capt. Floyd M. Burgeson, formerly of Des Moines. "As American surgeon at the Szubin, Germany, prisoner of war camp from October 1944 to January 1945," the citation read, "he displayed marked devotion to duty and high professional skill in conserving the health and improving the well-being of many hundreds of American officer prisoners of war." Dr. Burgeson graduated from the State University of Iowa College of Medicine, Iowa City, in 1934 and entered the service Feb. 10, 1941.

Merle M. Musselman

The Bronze Star was recently awarded to Capt. Merle M. Musselman, formerly of Tucson, Ariz. The citation stated that "while a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945 he performed outstanding services as chief of the surgical service and ward surgeon in a general hospital. With impro-

vised, makeshift equipment and depleted medical supplies he labored against great odds and on a starvation diet. He cheerfully assumed additional duties as chief of laboratory and x-ray service and of attending surgeon. His devotion to duty and unflinching courage, his outstanding performance under extremely difficult and hazardous conditions were an inspiration to the entire prison camp." Dr. Musselman graduated from the University of Nebraska College of Medicine in 1939 and entered the service July 1, 1941.

Captain Laurence K. MacDaniels

The Bronze Star was recently awarded to Capt. Laurence K. MacDaniels, formerly of Portland, Ore., for work in Belgium and Germany. "As commanding officer of the battalion medical detachment, he constantly served as an inspiration to his men. On numerous occasions he courageously ignored enemy artillery and small arms fire to render prompt and effective treatment to the wounded. Personal fatigue and unfavorable conditions did not deter him from his tasks. With indefatigable energy and profound judgment he rigorously trained the men of his detachment in the performance of their vital duties, never hesitating to instruct them by his personal example." Dr. MacDaniels graduated from the University of Oregon Medical School in 1941 and entered the service Aug. 1, 1942.

Lieutenant Colonel Hjalmar T. Gentle

Lieut. Col. Hjalmar T. Gentle, formerly of Medford, Ore., was recently awarded the Bronze Star. As commanding officer of the 9th General Dispensary, "he has been solely responsible for the efficient and effective manner in which it was set up, organized and operated. By virtue of his keen organizational ability, unerring sense of duty and professional knowledge, he has made it possible for the dispensary to serve the entire headquarters with the least amount of inconvenience and the highest type of efficiency." Dr. Gentle graduated from the University of Oregon Medical School, Portland, in 1929 and entered the service Aug. 11, 1941.

Captain James W. Wiley

The Air Medal was recently awarded to Capt. James W. Wiley, formerly of Portland, Ore., "for meritorious achievement while participating with the 493d Bomber Group in heavy bombardment missions in air offensives against the enemy over Europe. The courage, coolness and skill displayed by this officer on these occasions reflect great credit on himself and on the armed forces of the United States." Dr. Wiley graduated from the University of Oregon Medical School, Portland, in 1933 and entered the service Oct. 28, 1942.

Captain Edmund A. Melvin

The Air Medal was recently awarded to Capt. Edmund A. Melvin, formerly of Gulfport, Miss., "in recognition of meritorious achievement while participating in aerial flights in the European Theater of Operations." Dr. Melvin graduated from the University of Tennessee College of Medicine, Memphis, in 1938 and entered the service Feb. 17, 1942. Dr. Melvin also wears the Distinguished Service Unit citation badge awarded his group for its performance during the "Battle of the Bulge" in December 1944.

Major Oram R. Lawry Jr.

Major Oram R. Lawry Jr., formerly of Portland, Maine, was recently commended by the commanding officer of the 65th General Hospital for his clinical work with that medical unit. Dr. Lawry graduated from the University of Pennsylvania School of Medicine, Philadelphia, in 1939, the Medical Field Service School, Carlisle Barracks, Pa., in 1941 and the Command and General Staff School, Fort Leavenworth, Kansas, in 1943. He entered the service in July 1941.

Captain Katsumi J. Nakadate

Capt. Katsumi J. Nakadate, formerly of East Chicago, Ind., was awarded the Bronze Star for "outstanding first aid work during a glider borne troop action last March, near Hussmanshof in Germany." Dr. Nakadate graduated from the University of Oregon Medical School, Portland, in 1939 and entered the service May 6, 1943.

MISCELLANEOUS

HOSPITAL WORKERS NEEDED

More than 130,000 professional and nonprofessional workers, in addition to more trained volunteer nurses' aides, are needed in the nation's civilian hospitals. The Public Health Service of the Federal Security Agency, the War Manpower Commission and the Veterans Administration are sponsoring a recruiting drive in cooperation with the American Red Cross, the National Nursing Council for War Service and the American Hospital Association. Urgently needed at once are 30,000 graduate nurses for general, tuberculosis and psychiatric hospitals, 8,000 graduate nurses for public health nursing, 2,000 graduate nurses for Veterans Administration hospitals (this is in addition to 3,000 more who will be needed by January 1947) and 90,000 non-nursing hospital workers. Besides these paid workers, 40,000 already trained volunteer nurses' aides are needed to augment the number now giving many hours of service to the hospitals.

Within a few months large numbers of nurses released by the military services and closed war plants may transfer their services to hospitals, but no appreciable increase in the number of women taking such positions is expected immediately. Of the 13,000 industrial nurses, many are expected to remain in the industrial field. Of the Army and Navy nurses released, it is expected that many will take well deserved rests before they take up new duties in civilian hospitals or as private nurses. The first classes of cadet nurses, now in training, will not become graduate nurses until next July. The need for the additional nurses is due to the patient load, which is heavier today than at any time since 1940, as well as to the withdrawal in the past of nurses for the armed services and war plants.

At the request of the Surgeon General the Public Health Service, the American Hospital Association recently conducted a survey to learn the extent of personnel shortages and to determine the seriousness of the need. The survey, which covered 1,060 hospitals affiliated with the association, reported that 23 per cent had closed beds, wards and sections as a result of the shortage of nurses and other personnel. Hundreds of hospitals still have long waiting lists of patients requiring hospitalization. This is in spite of the fact, the survey report stated, that many nurses are working longer shifts and most of them under unwholesome tension.

Hospitals are crowded more than ever for three principal reasons, the Office of War Information was told: 1. Higher incomes and hospitalization plans have made hospital care financially possible for many who could not previously afford it. 2. The population is growing: babies born in hospitals increased from 1,214,492 in 1940 to 1,919,976 in 1944. 3. An overworked doctor can attend more patients when they are brought together in one hospital under professional nursing care than if left in scattered homes. The trend has been strongly in this direction.

The association survey disclosed that in 1944 general hospitals with schools of nursing attached were able to provide patients only thirty-five minutes care by graduate staff nurses every twenty-four hours, or about half the minimum. The remainder of the care was given by student nurses. To supplement nursing staffs in these hospitals 30,000 more nurses are needed, according to the survey. The recommended care for a patient during a twenty-four hour period (under wartime conditions) in a general hospital without a school of nursing is two and one-half hours. However, in 1944 only one hour and ten minutes per day was available to patients.

The shortage of nurses was said to be even more acute in tuberculosis and psychiatric hospitals. There has been a decrease of 31.3 per cent since 1941 in the number of nurses employed in nonfederal psychiatric hospitals. There are now 4,277 nurses caring for 537,821 patients, or only 1 nurse to care for 125 mentally ill patients. There has been a decrease of 36.7 per cent in the number of nurses employed in tuberculosis hospitals since 1941. This means that 4,284 nurses are caring for 58,610 patients, almost 14 to 1 nurse.

The Veterans Administration reports that the ninety-eight veterans' hospitals are for the most part understaffed to the danger point. There are three types of veterans' hospitals: general medical and surgical, neuropsychiatric and tuberculosis. The need for 8,000 more public health nurses is based on a

wartime standard of 1 nurse to 5,000 people for every state. At present there is 1 nurse for each 6,000 population. Vast shifts in population as families moved into war industry centers or followed service men around the country created new needs for public health nurses, the Public Health Service reported. About 3,000 public health nurses have gone into military service. Many of these vacancies have remained unfilled. The 90,000 more men and women—other than nurses or nursing personnel—who are needed include highly skilled technicians, orderlies, laundrymen, electricians, plumbers, janitors and chiefs.

More than 200,000 women in the United States have completed nurses' aide training, but for a variety of reasons many of them are not now devoting any time to hospitals. It is probable, the Red Cross states, that some hospitals already have a full complement of volunteers. However, many hospitals are pleading for them. The Red Cross also said that a minimum of 3,000,000 additional persons should receive training in home nursing. Four types of courses are offered: (1) a standard twenty-four hour course for adults, (2) six two hour lessons in the care of the sick, (3) the course for college students, offered in the fall of this year, (4) the high school course, which is sometimes combined with home economics or science courses.

WARTIME GRADUATE MEDICAL MEETINGS

The sudden termination of active hostilities in both Europe and Japan, with the resultant anticipated redeployment and separation of physicians from service, has compelled the Central Committee to make preparations for the conclusion of the Wartime Graduate Medical Meetings. Unless more urgent demands are forthcoming, its activities will terminate as of Dec. 31, 1945.

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Birmingham General Hospital, Van Nuys: Recent Developments in Surgical and Public Health Antisepsis, Dr. Fred J. Moore, October 10; Communicable Diseases, Major Norman Nixon, October 24; Acute Infectious Mononucleosis, Capt. Charles H. Marple, October 24.

A. S. F. Regional Hospital, Camp Haan: Neuropsychiatry, Lieutenant Commander Nichols, October 2.

Camp Cooke Station Hospital, Lompoc: Recent Developments in Diabetes, Dr. Howard F. West, October 3; Traumatic Surgery of the Urinary Tract, Capt. D. W. Atcheson, October 17.

Hoff General Hospital, Santa Barbara: Recent Developments in Diabetes, Dr. Howard F. West, October 3; Traumatic Surgery of the Urinary Tract, Capt. D. W. Atcheson, October 17.

Torney General Hospital, Palm Springs: Cardiac Pain, Capt. Arthur A. Twiss, October 2; Acute Nephritis, Professor Lyttle, October 16.

U. S. Regional Hospital, Pasadena: Thoracic Surgery, Comdr. W. L. Rogers, October 8.

U. S. Naval Air Training Station, San Diego: Acute Infectious Hepatitis, Col. Irving Wright, October 5; Psychosomatic Medicine, Major Milton Miller, October 19; Headache, Capt. Oscar Sugar, October 19.

A. A. F. Regional and Convalescent Hospital, Santa Ana Army Air Base: The Streptococcus Problem, Lieut. Comdr. George R. Underwood, October 2; Endocrinology, Dr. Hans Lissner, October 18.

U. S. Naval Hospital, San Diego: Peripheral Vascular Problems, Col. Irving Wright, October 4.

U. S. Naval Hospital, Mare Island: Newer Trends in Syphilotherapy, Dr. Norman N. Epstein, October 5; Acute Sinusitis, Dr. Lewis F. Morrison, October 26.

U. S. Naval Hospital, Treasure Island: Skeletal Injuries to the Extremities, Dr. Frederick C. Bost, October 5; Peritoneal Injuries and Infections, Dr. Alson R. Kilgore, October 26.

Station Hospital, Camp Roberts: Peripheral Vascular Disease; Surgical Aspects, Dr. M. Laurence Montgomery, October 13.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Sept. 17, 1945.

General Hawley Named Veterans Surgeon General

In his reorganization of the Veterans Administration along army lines, with thirteen branch offices set up in districts roughly comparable to Army Service Commands, Gen. Omar N. Bradley has named Major Gen. Paul R. Hawley as the agency's acting Surgeon General. Dr. Charles M. Griffith, medical director, becomes an assistant to General Hawley. The Medical Branch has also been raised to independent status.

A. D. Hiller, formerly executive assistant to the administrator, also will assist General Hawley in handling administrative affairs. General Bradley has appointed Col. Eldon L. Bailey, recently released from the Army, to be his executive assistant, with duties to be roughly those of a chief of staff. Decentralization is effected through creation of the thirteen branches, which will supervise the work of fifty-three existing offices and about one hundred hospitals, formerly run from the Washington central office. Control of the agency will also be distributed among fourteen top assistants to General Bradley. During the two decade administration of Brig. Gen. Frank T. Hines, control was held by four deputy administrators, the so-called Four Horsemen. All four have been held in key posts, the shakeup leaving old time appointees in ten of the top jobs. General Bradley declared that all appointees, civilian and military, are in an "acting capacity" and none of the appointments are permanent.

Major General Hawley is named assistant administrator for medicine and surgery. Formerly chief surgeon of the European theater, he has been serving as personal aide on medical affairs to General Bradley and will now serve as "surgeon general." The director of medical and hospital service served in the former setup under a civilian who was the assistant administrator in charge of medical and domiciliary care, construction and supplies. Now an almost autonomous medical branch is created, as requested in bills before both branches of Congress and urged by elder statesman Bernard Baruch.

The thirteen branches will be established as soon as personnel are trained and space is available. They take immediate charge of hospitals, domiciliaries and regional and subregional officers. Later they will handle insurance and dependents' claims now handled by the central office.

Congress Urged to Aid Research on Artificial Limbs

Col. Leonard T. Peterson, Army chief of orthopedic surgery, told the House Labor Committee's subcommittee to aid the physically handicapped, that failure of Congress to support research in better artificial limbs will mean that limbs will be no better twenty-five years hence than they are now. He was one of a number of witnesses heard during three day hearings before Representative Augustine B. Kelley, Democrat of Pennsylvania, subcommittee chairman.

Denial of Deaths from Delayed Radioactivity of Atomic Bomb

Scientists who developed the atomic bomb deny Japanese propaganda claims that delayed radioactivity could have caused deaths. They state that the radioactive gamma rays released by the atomic bomb may kill instantly or cause death within a few days. These gamma rays will penetrate an ordinary wall, but a foot of concrete stops them. The rays travel with the speed of light. Some atomic bomb victims in Hiroshima and Nagasaki were doubtless killed by instantaneous radiation at the time of the explosion. But these instant rays are not to be confused with delayed radioactivity. Major Gen. Leslie R. Groves, director of the atomic bomb project, says that the

atomic bomb will actually kill in some fifteen different ways, including concussion, blast, fire, exploded missiles, falling buildings and lack of medical attention. United States Army scientific observers were flown to Japan after the surrender to check on bomb damage and the Jap propaganda claims.

Medical Legislation

MEDICAL BILLS IN CONGRESS

National Neuropsychiatric Institute

Hearings have been scheduled by a subcommittee of the House Committee on Interstate and Foreign Commerce on H. R. 2550, a bill to provide for, foster and aid in coordinating research relating to neuropsychiatric disorders and to establish the National Neuropsychiatric Institute. Hearings began Tuesday, September 18.

Prosthetic Appliances

Representative Rogers, Massachusetts, proposes by H. R. 4911 to direct the Secretary of War to cause to be conducted, by the appropriate agency or agencies in the War Department, experimentation, studies and research for the purpose of aiding in the rapid development and prompt manufacture of more adequate and efficient prosthetic appliances and parts of such appliances. This bill, too, would direct the Secretary of War to allocate funds to such corporations and business firms as he deems best qualified, to be expended in conducting experimentation, studies and research with respect to prosthetic appliances. Another bill introduced by Representative Rogers, H. R. 4012, is similar to the preceding bill with the exception that it directs the Administrator of Veterans Affairs to cause to be conducted by the Veterans Administration such experimentation and directs that official to allocate funds to corporations and business firms.

Miscellaneous

Representative Kelley, Pennsylvania, has introduced H. R. 3994, a bill to provide for the general welfare by enabling the several states to make more adequate provision for the health and welfare of mothers and children and for services to crippled children. This bill is identical with the Pepper bill, S. 1318, and the Norton bill, H. R. 3922.

H. R. 3972, introduced by Representative Bailey, West Virginia, proposes to encourage the prevention of stream pollution by allowing amounts paid for plants for the treatment of industrial waste as a deduction in computing net income.

Coming Medical Meetings

American Medical Association House of Delegates, Chicago, Dec. 3-6.
Dr. Olin West, 535 N. Dearborn St., Chicago 10, Secretary.

Association of American Medical Colleges, Pittsburgh, Oct. 29-31.
Dr. Fred C. Zapffe, 3 S. Wabash Ave., Chicago, Secretary.

Delaware Medical Society of Wilmington, Oct. 8-10. Dr. W. H. Speer, 917 Washington St., Wilmington, Secretary.

Indiana State Medical Association, French Lick, Nov. 6-8. Mr. Thomas A. Hendricks, 23 E. Ohio St., Indianapolis 4, Secretary.

Kentucky State Medical Association, Lexington, Oct. 29-31. Dr. P. E. Blackerby, 620 S. Third St., Louisville, Secretary.

New York Medical Society of the State of, House of Delegates, Buffalo, Oct. 8-9. Dr. W. P. Anderson, 292 Madison Ave., New York 17, Secretary.

Omaha Mid-West Clinical Society, Omaha, Nebraska, Oct. 22-26. Dr. R. W. Fouts, 107 S. Seventeenth St., Omaha, Secretary.

Pennsylvania Medical Society of the State of, House of Delegates, Philadelphia, Oct. 23-24. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Virginia Medical Society of, House of Delegates, Roanoke, Oct. 22-23. Miss Agnes V. Edwards, 1200 Clay St., Richmond 19, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

University News.—Dr. Paul M. Aggeler, assistant professor of preventive medicine, University of California Medical School, San Francisco, has been named assistant clinical professor of medicine and preventive medicine.

Funds for Psychiatric Clinic.—Governor Warren recently signed a bill appropriating \$100,000 to purchase a site for a psychiatric clinic in Los Angeles. According to *California and Western Medicine* the clinic will be patterned after the Langley Porter Clinic established by the state in San Francisco a few years ago (*THE JOURNAL*, Feb. 27, 1943, p. 690). The clinic is to be devoted to research, teaching and treatment.

San Francisco Society Appoints Executive Secretary.—Mr. Frank J. Kihm, since 1938 city editor of the *Wall Street Journal*, Pacific Coast edition, has been appointed executive secretary of the San Francisco County Medical Society, a newly created position. Mr. Kihm was released from active duty with the U. S. Marine Corps September 1. He was to take up his new work with the county medical society September 15.

CONNECTICUT

Sanitary Code Amended.—A recent amendment to the Connecticut Sanitary Code, effective July 1, provides that, within twenty-four hours of the receipt of a prisoner who may have been exposed to a communicable disease, the prison or jail physician must be notified, who in turn must make a routine medical examination, including blood tests for syphilis and a smear and culture for gonococcal infection. On expiration of the sentence any person having syphilis or gonorrhea whether in an infectious or a noninfectious stage and in need of further follow-up treatment shall be reported to the state department of health. Another amendment discusses approved laboratories in using a standard serologic test for syphilis and still another states that, when the control or release of a case, contact or carrier of a communicable disease is dependent on laboratory findings, the specimens on which such findings are based shall be examined by the bureau of laboratories of the state department of health or by a laboratory specifically approved for the purpose by the state department of health. The health officer shall by himself or his agent secure and submit release cultures or specimens for examination.

FLORIDA

Wilson Sowder Named State Health Officer.—Dr. Wilson T. Sowder, U. S. Public Health Service, has been appointed health officer of Florida to succeed Dr. Henry Hanson, Jacksonville, who will retire September 25. Dr. Sowder graduated at the University of Virginia Department of Medicine, Charlottesville, in 1932. Dr. Hanson has held the position since July 1942.

GEORGIA

William Friedewald Heads New Department.—On September 1 Dr. William F. Friedewald, member of the staff, International Health Division, Rockefeller Foundation, New York, became professor of bacteriology and chairman of the newly created department at Emory University School of Medicine, Atlanta. Dr. Friedewald, who graduated at St. Louis University School of Medicine in 1935, has been with the Rockefeller Foundation since 1942.

ILLINOIS

New Chief of Health Service.—Dr. Marjorie M. Smarzo, Urbana, has been named head of the women's division of the University of Illinois Health Service, succeeding Dr. Maude Lee Etheredge (*THE JOURNAL*, August 18, p. 1179). Dr. Smarzo first came to the University of Illinois in 1930 as assistant hygiene and medical adviser for women. Previously she had been examining physician for the Bell Telephone Company in New York and New Jersey. In 1932 she left Illinois to become resident physician and professor of hygiene at Winthrop College, Rock Hill, S. C. Dr. Smarzo returned to the University of Illinois in 1937 and remained until 1942, when she left to become an examining physician at the Sangamon

Ordinance plant at Illiopolis, Ill. In 1943 she became college physician at New Jersey College for Women, New Brunswick, N. J., returning this summer to the University of Illinois Health Service. In her new position Dr. Smarzo will have the title of assistant professor in hygiene and medical adviser for women in charge of the women's division of the health service.

CHICAGO

Food Forum.—On September 25 the Food Forum will convene at the Hotel Continental to hear the following speakers: Col. Rohland A. Isker, Chicago Quartermaster Depot, Nutrition and Current Relief Feeding.

Dr. Paul R. Cannon, Relative Nutritive Values of Proteins as Influenced by Their Amino Acid Composition.

Dr. Samuel A. Levinson, Effect of Relief Protein Diet in Nutrition.

Society News.—The Chicago Laryngological and Otological Society will be addressed October 1 at the Hotel Continental by Comdr. Francis L. Lederer (MC) and Lieut. (jg) William G. Hardy, H(S), U. S. Naval Reserve, on "The Treatment and Training of the Hard of Hearing Person: A Program of Physico-Psycho-Social Therapy for Those with an Aural Handicap."

Faculty Changes at Northwestern.—Announcement was recently made of the retirement of Dr. Harry M. Richter, professor of surgery at Northwestern University Medical School, with the rank of professor emeritus. Promotions on the faculty include:

Dr. Smith Freeman, professor of physiology.

Dr. Leon Unger, associate professor of medicine.

Dr. Theophil P. Grauer, associate professor of urology.

Dr. Eugene B. Perry, assistant professor of urology.

R. Frederick Becker, Ph.D., assistant professor of anatomy.

Dr. Gerard N. Krost, assistant professor of pediatrics.

Maury Massler Goes to Italy on Medical Survey.—Maury Massler, D.D.S., assistant professor of histology in the University of Illinois College of Dentistry, became the representative of dental science in September in a medical survey of the medical effects of wartime nutritional shortages in Italy. He will take the place of Isaac Schour, D.D.S., professor and head of the histology department at the university, who is now with the medical group to organize and begin the work and who expects to return to the university October 1. Dr. Massler's leave extends from September 1 to February 1.

IOWA

New Professor of Pathology.—Dr. Emory D. Warner has been named professor and head of the department of pathology at the State University of Iowa College of Medicine, Iowa City, to succeed Dr. Harry P. Smith, who has joined Columbia University College of Physicians and Surgeons (*THE JOURNAL*, May 5, p. 42). Dr. Warner, associate professor of pathology at Iowa, graduated there in 1929.

Medical School Observes Seventy-Fifth Anniversary.—The State University of Iowa College of Medicine, Iowa City, will celebrate its seventy-fifth anniversary with a special program September 27-28. The program will include clinics, symposiums and ward walks as well as a series of demonstrations covering the specialties. Dr. Owen H. Wangenstein, professor of surgery, University of Minnesota Medical School, Minneapolis, will deliver the Paul Reed Rockwood Lecture on "The Ulcer Problem" and Dr. Ralph H. Major, professor of medicine, University of Kansas School of Medicine, Kansas City, the Mayo Lecture on "Hippocrates and the Island of Cos"; also included on the program will be the following, all of Iowa City:

Dr. William D. Paul, Physical Therapy in Arthritis.

Dr. William M. Hale, Influenza.

Drs. Willis M. Fowler and Milford E. Barnes, Malaria.

Dr. Elmer L. McGowan, Blood Bank.

LOUISIANA

Personal.—Dr. Jesse F. Tanner, DeFuniex, has been appointed coroner of Union Parish to complete the unexpired term of the late Dr. J. G. Taylor, Farmerville, who died May 16. —Dr. Charles F. Gelbke, Gretna, was awarded the annual plaque for outstanding civic service on the Westbank at the ninth annual banquet of the Westbank Rotary Club, held in the Gold Room of the Roosevelt Hotel, New Orleans, recently.

Grant for Study on Metabolic Diseases.—Eli Lilly and Company has made a grant of \$5,000 to the Alton Ochsner Medical Foundation for research, New Orleans, for the study of endocrine and metabolic diseases under the supervision of Dr. William Parson, New Orleans. Dr. Albert Segaloff, formerly of Vanderbilt University School of Medicine, Nashville, Tenn., who was to join the foundation staff on August 1, will have direct charge of the endocrine laboratory.

MARYLAND

Charles Davidson Named Acting Professor of Radiology.—Dr. Charles N. Davidson has been appointed temporary head of the department of radiology at the University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, pending the return of Dr. Walter L. Kilby from military service. Dr. Henry J. Walton, who had been professor since 1918 until a few years ago, when he was made professor emeritus, has been serving since Dr. Kilby entered the service.

MASSACHUSETTS

Graduate Seminar in Neurology and Psychiatry.—The eleventh postgraduate seminar in neurology and psychiatry will begin Monday, October 1, at the Metropolitan State Hospital, Waltham. The program consists of lectures, demonstrations and round table conferences in anatomy, applied physiology, pathology and roentgenology of the nervous system, clinical neurology, psychopathology and psychiatry. The lectures will be held every Monday from October 1 to December 10 and from Jan. 7 to April 22, 1946 in three sessions of two hours each. The printed schedule will be released shortly. The seminar is open to all graduate physicians. Those interested are requested to register October 1 at the Metropolitan State Hospital, 475 Trapelo Road, Waltham.

MICHIGAN

State Medical Meeting.—The 1946 annual session of the Michigan State Medical Society will be held at the Book Cadillac Hotel, Detroit, the week of Sept. 22, 1946.

Rheumatic Fever Control Conference.—The Michigan State Medical Society and the Michigan Crippled Children Commission sponsored a rheumatic fever control conference September 19-20 at the Book-Cadillac Hotel, Detroit. Among the participants were:

- Dr. Herman H. Riecker, Ann Arbor, The Rheumatic Fever Control Program in Michigan.
- Dr. John R. Paul, New Haven, Conn., Natural History of Rheumatic Fever, Epidemiology and Familial Aspects.
- Dr. Stanley Gibson, Chicago, Clinical Manifestations of Rheumatic Fever and the Determination of Rheumatic Activity.
- Dr. John F. Holt, Ann Arbor, Use of the X-Rays in the Diagnosis of Rheumatic Heart Disease.
- Dr. Gordon B. Myers, Detroit, Electrocardiogram in the Diagnosis of Rheumatic Heart Disease.
- Dr. James L. Wilson, Ann Arbor, Differential Diagnosis of Rheumatic Fever in Children.
- Dr. Joseph A. Johnston, Detroit, Chorea and Its Differential Diagnosis in Children.
- Dr. Thomas Duckett Jones, Boston, Prophylaxis and Treatment of Rheumatic Fever.

In addition round table discussions were held, among others, by Drs. Moses Cooperstock and Mark F. Osterlin, Ann Arbor. The program also included clinical demonstrations.

Institute for Occupational Health Research.—Articles of incorporation for a new nonprofit corporation to be known as the Institute for Occupational Health Research will be filed in Lansing next month, it was announced September 2. The institute will be staffed with specialists in the medical and engineering phases of employee health and will maintain research laboratories. Subject to approval by the board of education, the institute will be affiliated with and housed with Wayne University's new School of Occupational Health, whose program is entirely financed by the Medical Science Center. Dr. Raymond Hussey, dean of the school, will serve as director of the institute. The sum of \$750,000 is now being raised by the Medical Science Center to finance the joint program of the school and the institute for the first five years. The affiliated school and institute will be both a service unit for industry and an educational institution. The school will educate, on a postgraduate level, graduate doctors and engineers who wish to specialize in the field of occupational health. In addition, courses will be available to industrial physicians and hygiene engineers. Later the school will arrange special courses for the training of technicians. For graduate doctors and engineers the school will offer a two year course, of which half the time will be spent in plants. On graduation, doctors will receive the degree of doctor of industrial health, and engineers the degree of doctor of science in industrial health. The staff and laboratory of the institute will be available to industry at reasonable cost. In general it will concern itself with the health of all persons engaged in business and industrial occupations. It will accept a limited number of industrial concerns as clients and supervise their employee health programs, though it will at no time engage in the practice of clinical medicine. It will, on request, study the biologic effects, harmful or otherwise, of manufactured products and manufacturing processes on workers and

consumers. It will conduct researches in the field of occupational health and publish and disseminate information in this field. The School of Occupational Health, meanwhile, will utilize the institute's laboratory, experiments and employee health maintenance program as part of its instruction activities, much as a hospital is used for the teaching of medical students. It is anticipated that the school will be ready to accept enrolments by the fall of 1946. The institute will be in operation before that time. For the time being, both school and institute will be situated in one of the large houses recently condemned for the use of Wayne University. Eventually a building will be provided in the Medical Science Center. Dr. Hussey is now canvassing the country for prominent medical and engineering personnel in the field of industrial health. These will comprise the faculty of the school and staff of the institute. In a statement to the press, Dr. Hussey stated that there is no institution of the kind now in existence anywhere in the world. Emphasis will be placed on the humanistic approach to the problem and the concept of occupational health which recognizes the study of health for its own sake rather than regarding health as absence of disease. Dr. Hussey stated that the staff will be prepared to go into a plant, survey it and provide full employee health supervision of both an engineering and a medical nature, making recommendations on ventilation, clothing, protective devices and all other subjects relating to employee health. The actual practice of medicine will be left to the medical profession. The institute will train industrial physicians and engineers who wish to specialize in such employee health matters as illumination, noise, ventilation, temperature and humidity, plant sanitation, hygiene and safety.

MISSOURI

Fall Clinical Conference.—The twenty-third annual fall clinical conference of the Kansas City Southwest Clinical Society will be held at the Little Theater, Municipal Auditorium, Kansas City, October 1-2. The program will consist of symposiums on:

- Cardiology—Dr. Ira H. Lockwood, Kansas City, director; Drs. C. G. Claude F. Dixon, Rochester, Minn.; Leo G. Col. Howard A. Rusk, M. C., participants.
- Diseases—Dr. Joseph E. Welker, Kansas City, Hansen, Galveston, Texas; Capt. Alphonse McMahon (MC) and Dr. Rigler, participants.
- Rehabilitation and Tropical Diseases—Dr. Lewis G. Allen, Kansas City, director; Colonel Rusk, Lieut. Col. Samuel T. Helms, M. C., and Major Wilson C. Merriman, M. C., participants.
- The Chest—Dr. Herbert L. Mantz, Kansas City, director; Dr. Everts A. Graham, St. Louis; Col. John B. Graw, M. C., and Dr. Rigler, participants.
- Endocrinology—Dr. William Merritt Ketcham, Kansas City, director; Dr. Barborka, Dr. Ralph E. Campbell, Madison, Wis., Dr. Hansen and Dr. Frank D. Dickson, Kansas City, director; non L. Hart, M. C., and Dr. Roland M. Klemme, St. Louis, participants.

Other speakers who will participate include Col. Edgar V. Allen M. C., and Col. Grover C. Penberthy, M. C.

MONTANA

Personal.—Dr. Niels A. Kaa, Corvallis, has been appointed health officer of Ravalli County.

Montana Health.—The Public Health League of Montana has brought out a publication entitled *Montana Health*. The first issue, dated September, is devoted to a discussion of the health activities of the state as well as in agencies interested in the progress of health education. The Public Health League of Montana was formed last year (*THE JOURNAL*, Nov. 25, 1944, p. 846).

OKLAHOMA

License Revoked.—The license to practice medicine of Dr. John Henry Lee Staples, Afton, was revoked June 14 for a narcotic violation (*THE JOURNAL*, March 24, p. 727).

Pathologists Hold First Annual Meeting.—The Oklahoma Association of Pathologists, at its first annual meeting recently, selected Drs. Howard C. Hopps, Oklahoma City, president, Leo Lowbeer, Tulsa, vice president and Bela Halpert, Oklahoma City, secretary-treasurer. Meetings of the association have been held monthly since it was formed in December 1944.

OREGON

Dr. Aufranc Named Assistant State Health Officer.—Dr. Will H. Aufranc, a regular corps officer of the U. S. Public Health Service with rank of surgeon, is on loan to the state of Oregon to act as assistant state health officer. Dr. Aufranc also has charge of the county health units program as well as the state venereal disease control program.

Personal.—Dr. Clifford E. Hardwick, Hood River, has been named a member of the Oregon State Board of Health to succeed Dr. Thompson Coberth, The Dalles, who resigned.—Dr. Elizabeth Bishop, Baker, health officer of Union and Baker counties, was recently elected president of the Oregon Public Health Association.—William Fitch Allen, Ph.D., professor of anatomy and head of the department, University of Oregon Medical School, Portland, received the doctor of science degree from the university at its recent commencement in recognition of his contributions to anatomy and physiology and his services as a teacher.

New University Hospital Approved.—Voters of Oregon endorsed the proposed building program submitted by the legislature to aid the higher educational facilities of the state and certain state institutions coming under the jurisdiction of the state board of control, according to *Northwest Medicine*. Erection of a University Hospital on the University of Oregon Medical School campus, Portland, in addition to the existing hospitals in the university group, was among the items approved. The journal states that the house of delegates of the state medical society is on record as approving operation of such a hospital at the indigent level.

Physicians Purchase Coffey Hospital.—A group of fourteen Portland physicians has purchased the Coffey Memorial Hospital, Portland. Incorporated as Physicians and Surgeons Hospital of Portland, the new owner has declared itself a nonprofit organization and announced plans to develop a complete community hospital, according to *Northwest Medicine*. Stockholders of the new group include Drs. Johnson D. Leonard, president; Ira A. Manville and Harry M. Hendershott, vice presidents; Jerome L. Holzman, treasurer, Horace L. Rosenberg, secretary, Aubrey M. Davis, Millard B. Taylor, Waldo G. Homan, Alfred Hutchinson, Linford S. Besson, Rudolf A. Bissett, William B. Hare, Jesse L. Ray and Wilford H. Belknap.

PENNSYLVANIA

Harry Weest Named Secretary of Health.—Lieut. Col. Harry W. Weest Jr., formerly chief surgeon of the 28th division, has been appointed secretary of health of Pennsylvania to succeed Dr. Alexander H. Stewart, Harrisburg, who died July 31. Colonel Weest was commissioned a first lieutenant in the Pennsylvania National Guard in 1922 and was named division surgeon of the 28th division when Governor Edward Martin was major general in command. Colonel Weest graduated from Jefferson Medical College of Philadelphia in 1919 and practiced medicine in Altoona, where he was on the staff of the Altoona and Mercy hospitals.

Philadelphia

Committee for the Study of Pelvic Cancer.—The Philadelphia Obstetrical Society has created a committee for the study of pelvic cancer the primary aim of which is the detailed study of the "delay period" in every case of death from pelvic cancer. The plan has the approval and cooperation of the Philadelphia County Medical Society and the Philadelphia Department of Public Health. The committee will investigate in detail every death from pelvic cancer occurring in Philadelphia. An investigator will make a special study of that period of the patient's history from the onset of symptoms until adequate therapy has been instituted, the so-called "delay period." An attempt will be made in each case to explain the definite reason for any "delay" and to assign the responsibility to the patient, the doctor, the hospital or to all, as the case may be. The facts obtained from this study will be used as a means of educating the physicians of Philadelphia. The committee will meet each month to review the deaths of the previous month in an effort to decide from the facts where the blame for delay should be placed. The data for these cases will be obtained from the physicians in charge of the case, from the hospital charts and, when necessary, with the permission of the attending physician, from the relatives or the family of the patient. The data will be secured by a paid investigator of the committee who will personally call on the physicians, hospitals or others. As the work of this committee progresses and the monthly review of cases is carried on, the physicians in each case will be asked to take part in the discussion. Their presence at the discussion of their cases and the presence of other interested physicians at these open meetings will be a means of informing physicians of the work of the committee and of sensitizing them to the importance of keeping a "high index of suspicion" for pelvic cancer. According to an announcement, the committee is believed to be the first of its kind to be formed in this country. No previous attempt to "check up" on the physician and his handling of

cancer cases has ever been done, it was stated. The committee is patterned after the Philadelphia Maternal Welfare Committee and hopes to accomplish for pelvic cancer what the maternal welfare committee has accomplished in reducing maternal mortality in Philadelphia. The committee, which has been organized to work with and for the physicians of Philadelphia, is financed by grants from the American Cancer Society and from the Philadelphia Obstetrical Society, which grants are barely sufficient to meet the present needs of the committee. Members of the newly formed committee are Drs. John Y. Howson, chairman; George A. Hahn, treasurer; Clayton T. Beecham, Leib J. Golub, Thaddeus L. Montgomery, Myer Solis-Cohen, Elizabeth S. Waugh and Philip F. Williams. In a statement the committee states that, generally speaking, one of the three factors is involved in any case where the "delay period" is prolonged: the physician, the patient, and the physician and the patient combined. The physician has been responsible for a prolonged "delay period" on the following counts: failure to make a diagnosis, wrong advice, wrong treatment, no treatment, failure to examine the patient adequately. The patient has been responsible because of fear of operation, fear of going to a doctor, fear of having cancer, economic reasons, and the like. The two factors are combined when both physician and patient are at fault. The committee believes that programs to educate the public have been worth while because of the increasing response of the public. Credit is ascribed also to various cancer detection clinics that have been established throughout the country. These, however, are believed not to have reached a majority of the people, indicating that the best approach still is through the practicing physician or family doctor.

SOUTH CAROLINA

Changes in Health Officers.—Dr. Edmond J. Bryson, Liberty, who has been serving as health officer for Oconee and Pickens counties, has been assigned health officer for Pickens County only and Dr. Furman T. Simpson, Westminster, will have charge of the Oconee Unit. The change was effective June 1.

Physicians Give 250 Years of Service to State.—At a meeting of the staff of the York County Hospital, Rock Hill, recently it was revealed that five physicians in attendance at the meeting had practiced medicine in South Carolina for a total of 250 years. The physicians and their years of service in the state are Dr. Joseph H. Saye, Sharon, 62 years; William A. Hood, Hickory Grove, 56 years; Charles B. Harrell, Rock Hill, 47 years; James R. DesPortes, Fort Mill, 45 years; James B. Elliott, Fort Mill, 40 years. The *Journal of the South Carolina Medical Association*, in an additional comment, claimed that this is a record unparalleled in any county of similar population, 58,000, in the United States.

WEST VIRGINIA

Changes in Health Officers.—At a special meeting of the Public Health Council in August the following city and county health officers were appointed: Drs. James E. Coleman (reappointed), Fayetteville, of Fayette County; Edgar H. Willard, Berkeley Springs, of Morgan County; Roscoe G. Stotts of Kenova, and James A. McClung of Richwood.

License Revoked.—The license of Dr. Ballard R. Gibson, Omar, has been revoked by the public health council on the grounds that credentials presented from the state of Tennessee for the procurement of licensure in West Virginia by reciprocity were fraudulent and that the certificate of premedical education at Pikeville (Kentucky) College was likewise fraudulent, according to the West Virginia State Medical Association. Dr. Gibson was formerly located at McAndrews, Ky.

ALASKA

Health Education Fellowship and Surveys.—The first fellowship in health education granted in Alaska has been awarded to Mrs. Kathleen Kimble, Alaska Native Service teacher at Point Hope. On completion of the course at the School of Public Health of the University of North Carolina, Chapel Hill, under the auspices of the National Foundation for Infantile Paralysis Mrs. Kimble will return to Alaska to become health education supervisor for the Alaska Native Service.—The division of maternal and child health and crippled children's services of the Alaska Department of Health, in cooperation with the medical profession, is conducting a survey throughout the territory to determine the prevalence of rheumatic fever in Alaska.—The department of health, the

department of education and the Alaska Native Service, in anticipation of establishing a division of rehabilitation in Alaska, is making a survey to ascertain the number of cases of deafness, blindness and speech defects in Alaska.

HAWAII

Personal.—Dr. Samuel D. Allison, for more than three years control officer of the division of venereal diseases in the board of health, Territory of Hawaii, has been given a temporary appointment of director of public health during the absence of Dr. Richard K. C. Lee, Honolulu, who has been given a year's leave for graduate study in New York.

Public Health Association Organized.—The Public Health Society of the Territory of Hawaii was recently organized. Officers include Kaarlo W. Nasi, P. A. sanitary engineer, U. S. Public Health Service, president; Theodore R. Rhea, C.P.H., director, Palama Settlement, vice president; Elmer J. Anderson, M.A., acting director of public health education, board of health, secretary, and Myrtle Payne, R.N., Castle and Cooke, Ltd., treasurer.

GENERAL

Special Society Election.—The following officers of the National Gastroenterological Association were recently reelected for a term of one year: Drs. Anthony Bassler, New York, president; Clarence J. Tidmarsh, Montreal, Canada, Harry M. Eberhard, Philadelphia, and William W. Lermann, Pittsburgh, vice presidents; Roy Upham, New York, secretary general; G. Randolph Manning New York, secretary, and Elihu Katz, New York, treasurer.

Survey of Needs for Day Care of Children.—The Child Welfare League of America has launched a nationwide survey for needs of day care of children, according to the *New York Times*. The work was started in anticipation of the emergency foreseen in the termination by October 31 of FWA of funds for children of working mothers. Howard W. Hopkirk, New York, executive director of the league, called for prompt and accurate reporting from 700 member agencies and affiliates in forty-three states "so that an up-to-date and correct picture of the situation may be presented to the President, who has power to continue such programs beyond November 1 if he finds proof that an emergency exists."

The Scudder Missionaries Return to Posts.—Two physicians of one family left for India on the *Gripsholm* August 28 to return as medical missionaries. They included Dr. Ida S. Scudder, who went to India in 1900 to serve forty-one years after being graduated at the Cornell University Medical College, New York, in 1899, and Dr. Lewis R. Scudder, physician in charge of a hospital at Kuwait, Arabia, Asia. According to the *New York Times* the Scudders are carrying out a family tradition started in 1819 by Dr. Ida S. Scudder's grandfather, also a physician. With Dr. Lewis Scudder were his wife and two children. Dr. Ida S. Scudder returned to the United States in 1941 but is going back to the All-India Christian Medical College as president emeritus to help develop a medical center there. Her niece, Dr. Ida B. S. Scudder, is professor of radiology and medicine at the All-India Christian Medical College, which was founded in 1918 at Vellore, India, and was formerly known as the Missionary Medical College for Women.

Changes in Status of Licensure.—The California State Board of Medical Examiners announces the following actions taken during its meeting in San Francisco, July 9-10:

Dr. John J. L. Doyle, Chico, license restored, July 9, and placed on five years' probation without narcotic privileges and with the proviso that he report to the board annually.
Dr. Milton S. McMurry, license restored, July 9, and placed on five years' probation (no restrictions as to narcotics, as there was no narcotic charge originally involved). Dr. McMurry must abide by all laws and report to the board annually.
Dr. Samuel J. Apfel, Brooklyn, license to practice in California revoked, July 10, because of revocation in another state.
Dr. James A. Hadley, Jamestown, placed on probation for a period of five years, without narcotic privileges and report annually to the board.
Dr. Benjamin F. Johnson, Jackson, Miss., California certificate revoked, July 10, because of revocation by another state.
Dr. Richard E. Orme, San Francisco, on July 10 placed on one year probation for violation of section 2392 of the Business and Professions Code, aiding an unlicensed practitioner. (No narcotic restrictions.)

The State Board of Medical Examiners of Georgia at a meeting, June 20, revoked the license to practice medicine of Drs. Grady L. Carter, Talbotton, and John Henry Moore Jr., Atlanta, and at a meeting, July 18, the license of Lucius H. Stinson, Augusta, was revoked. The Michigan State Board of Registration in Medicine at a meeting June 12, revoked the Michigan license to practice of Dr. David Friedman,

Detroit, for unprofessional and dishonest conduct and of Dr. Carl W. Wagar, Kalamazoo, for unprofessional and dishonest conduct. In New Hampshire the license to practice of Dr. Richard Lewis Barker, Derry, was revoked on July 11 on grounds of personal habits that were such as to unfit him for the practice of medicine, according to the state board of registration in medicine.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended September 8 have been received from the division of public health methods, U. S. Public Health Service, as follows:

	Poliomyelitis			Poliomyelitis	
	Week Ended Sept. 8, 1945	Week Ended Sept. 9, 1944		Week Ended Sept. 8, 1945	Week Ended Sept. 9, 1944

North Carolina...	11	26			

The seasonal peak for 1945 was probably reached during the week ended August 25, when 931 cases were reported. This is peak on the basis of dates of reports; peak by onset of cases would probably be a week or ten days earlier.

American Ophthalmological Society.—The annual meeting of the American Ophthalmological Society will be held at the Homestead, Hot Springs, Va., November 12-14. Among the speakers will be:

Col. Derrick T. Vail Jr., M. C., An American Ophthalmologist in Europe.
Dr. Donald J. Lyle, Cincinnati, Laurence-Moon-Biedl Syndrome.
Dr. Burton Chance, Philadelphia, The Exposing and Fixing of the Eye in the Early Days of Cataract Extraction.
Dr. Eugene M. Blake, New Haven, Conn., Cultivation of Human Tumor Tissue in the Anterior Chamber of the Guinea Pig Eye.
Dr. Wendell L. Hughes, Hempstead, N. Y., Uses of Air in Ophthalmology.
Dr. M. Hayward Post, St. Louis, Dust Borne Infection in Ophthalmic Surgery.
Dr. Alfred Cowan, Philadelphia, Concerning Ocular Imagery.
Dr. Daniel B. Kirby, New York, Paralysis of Ocular Elevation With and Without Blepharoptosis.
Dr. Arthur J. Bedell, Albany, N. Y., Retinal Vessel Proliferation in Diabetes.
Dis. Algernon B. Reese and Frank Payne, New York, So-Called Persistent Tunica Vascularis Lenticis or Retrofetal Fibroplasia of Terry.
Dr. Albert D. Ruedemann, Cleveland, Full Plastic Eye Implant.
Dr. Philip M. Lewis, Memphis, Tenn., Penicillin in Gonococcal Conjunctivitis. Its Use in (About) 25 Cases Compared with the Sulfonamides in 173 Cases.
Dr. William H. Crisp, Denver, A Device for Group Demonstration of Astigmatism Tests.
Dr. Glen G. Gilson, Philadelphia, Marginal Myotomy: An Analysis of Twenty-Two Operations.
Drs. Everett L. Goar and Charles R. Potts, Houston, Texas, The Relationship of Rubella in the Mother to Congenital Cataracts in the Child.
Dr. Trygve Gundersen, Brookline, Mass., Vossius Ring in Ten Battle Casualties.
Drs. Conrad Berens and Hunter H. Romaine, New York, Choice of Sutures in Surgery of the Ocular Muscles.
Dr. Bernard Samuels, New York, Cataract Complicating Intraocular Tumors.
Dr. Maynard C. Wheeler, New York, Exophthalmos Caused by Eosinophilic Granuloma of Bone.
Dr. F. L. Philip Koch, New York, Intraocular Manifestations of Disseminated Lupus Erythematosus.
Dr. Francis Heed Adler, Philadelphia, Physiologic Factors in the Diagnosis of Superior Oblique and Superior Rectus Palsy.
Dr. Ramon Castroviejo, New York, Indications and Contraindications for Keratoplasty and Keratectomy.
Dr. Leslie C. Drews, St. Louis, An Accurate Method for Centering a Front Stop During Cycloplegic Refraction.
Dr. Walter S. Atkinson, Watertown, N. Y., Preliminary Report on Corneal Section with Long Bevel with Conjunctival Flap for Cataract Extraction.

The Sterilization, Care and Use of Syringes

Mild inflammations and infections not uncommonly follow the inoculation and injections which play so important a part in modern treatment. More severe and even fatal results sometimes occur and usually can be traced to some technical fault. These include cellulitis, lymphadenitis, abscesses, tuberculosis, tetanus, gas gangrene, infective hepatitis, malaria and meningitis (due to contaminated lumbar puncture needles). The Medical Research Council therefore appointed a committee of leading pathologists under the chairmanship of Prof. G. S. Wilson to report on the sterilization use and care of syringes. The committee presented a memorandum based on the experience of many workers and on bacteriologic tests, leading to recommendations which have been proved to be safe and practicable.

It states that complete bacteriologic sterility can be achieved only by use of the autoclave or hot air oven. Boiling in water will destroy all pathogenic bacteria except those that produce resistant spores. Chemical disinfectants if they kill spores at all, do so slowly and cannot always be relied on to destroy even nonsporing bacteria in syringes. A fresh sterile syringe and needle must be used for each injection or aspiration. In clinics where many injections of the same fluid are given the same syringe may be used for several subcutaneous or intramuscular—but not intravenous—injections, provided a fresh needle is used for each patient. A syringe that has been used for aspiration, e. g. of blood from a vein or of pus from an abscess or for intravenous injection, which always entails aspiration of blood must be cleaned and sterilized before it is used again. It is essential to keep syringes for injection separate from those used for aspiration. Syringes and needles require thorough cleaning after use, before resterilization. Sterilization methods may be unreliable if the syringe or needle contains dirt or coagulable protein. Contamination of syringes and needles may occur during assembly after sterilization as the result of contact with fingers, dust or droplets of saliva from either the doctor or the subject, or of contact of the needle with a nonsterile surface. Needles should be handled only with sterile forceps. Syringes with dry washed hands, care being taken to touch only the outside of the barrel and the handle of the piston. The handler should not talk, cough or sneeze over a sterile syringe. Persons with known or suspected upper respiratory infections must wear masks while carrying out injections. The practice of 'dishing up' a sterile syringe and needle in an open bowl, especially one which contains any liquid is condemned. Sterile syringes and needles must be placed in sterile covered containers. Use of a pocket handkerchief must at once be followed by thorough hand washing.

A National Maternity Service

Representatives of the British Medical Association have met representatives of the Royal College of Obstetricians and Gynecologists on the question of a national maternity service and particularly on the role of the general practitioner. A provisional agreement has been reached on the following points: 1. After qualification a practitioner needs adequate and regular experience in obstetrics. 2. Midwifery standards should be raised by (a) inclusion of a resident midwifery post in the pre-registration hospital posts proposed in the Goodenough report on medical education; (b) creating an increased number of resident obstetric posts available to recently registered practitioners; (c) organization of the proposed comprehensive medical service posts to secure for each pregnant woman a general practitioner,

a midwife and, where necessary, an obstetric specialist, (d) recognition for the purposes of the future service of those general practitioners who desire to undertake obstetrics provided they undertake sufficient to enable them to remain efficient.

The Title of "Nurse" to Be Restricted by Law

After October 15 the title of nurse can no longer be assumed by any one who wishes to do so. The minister of health has made it an offense to use the title unless the person doing so is a state registered or enrolled assistant nurse. Agencies supplying nurses must be licensed by the local authorities and must supply only those who are state registered, enrolled assistant nurses, midwives or members of other classes to be prescribed. There is to be an exception for children's nurses who may use the term unless circumstances suggest that they are something other than children's nurses. Other permitted uses are 'trained nurse' by those on the general part of the nurses list, 'maternity nurse' by midwives and 'student nurse' and 'pupil assistant nurse' by those training for state registration and for the Assistant Nurses Roll. The object of these orders is to protect the public against the use of the term 'nurse' by persons having no nursing qualification and against the risk of being supplied without their knowledge with the services of unqualified persons. Regulations also prescribe the form in which licenses for agencies are to be made and the form in which agencies must notify the nurse's qualification to the person employing her.

Disturbances of Pulmonary Ventilation

At the Robert Debre Clinic for Diseases of Children, Debre and his collaborators stress the frequency and variety of conditions capable of provoking disturbances of the pulmonary circulation and the polymorphism of these disorders. A foreign body, for example, can hinder the entry of air in a limited pulmonary area and thus create atelectasis; it can also cause a localized emphysema by a valve action, as shown by Chevalier Jackson. The mechanical obstruction may be accompanied by more or less severe reflex phenomena. An attack of asthma, which is also a reflex disturbance, can by itself cause grave modifications in the respiratory mechanism, which will further complicate the consequences of intrabronchial glandular hypersecretion. Many other causes injure in the same way either mechanically or by reflex action the pulmonary ventilation.

The difference between pulmonary collapse and atelectasis is that the collapse produces only incomplete pulmonary compression in which the pulmonary permeability is still preserved. There remains some functional action of the lung. In atelectasis the pulmonary collapse is complete and the compressed tissues are functionally eliminated, they are shriveled, somewhat hyperemic and appear on the screen as an almost complete opacity.

These phenomena are evanescent and changeable. They require repeated roentgenologic examination. They present special pathologic aspects. Debre and his collaborators designate them as 'pneumonoses' in contradistinction to the infectious pneumopathies or 'pneumonitis'. In older children the pneumonoses are generally associated with tuberculosis of the mediastinal lymph nodes, with a pneumonia with the infiltration of a foreign body or with a bronchial tumor. In infants the appearance is often sudden and spontaneous and the diagnosis is often made only by roentgenocopy. The evolution can be rapid, the young child may succumb with symptoms of paroxysmal dyspnea, cyanosis and collapse. At other times the disorder terminates without having noticeably disturbed the health of the child. The etiology of these accidents is often uncertain. Their course as well as their clinical and roentgenologic sign,

presents disconcerting variations. Asthma and whooping cough may be considered as belonging to the same nosographic family; with their peculiar roentgenographic picture they closely resemble emphysema.

The pneumonoses and the pneumonotic syndromes must be differentiated from pneumonitis just as the nephroses must be differentiated from the nephritides. "It is necessary to avoid the widespread tendency to attribute to an infectious process disturbances which in reality are associated with mechanical phenomena."

In the course of lectures given on this subject at the Clinic of Children's Diseases, the associates of Professor Debré have presented chapters on this new aspect of pulmonary disease. The tracheobronchial adenopathy, which was once considered important and was later disregarded, was assigned once more its role in the disturbances of the pulmonary circulation. These disturbances depend on bronchial compression by caseous adenitis; they lead sometimes to atelectasis and more rarely to localized emphysema. They are not characteristic and are not accompanied by pathognomonic physical signs. The diagnosis is made principally on the basis of the evolution of roentgenographic or tomographic records. Bronchoscopy also is helpful.

These ideas concerning the frequent existence of unrecognized atelectases or emphysemas in children have considerable importance. Besides their theoretical interest and their value for the knowledge of the normal and pathologic physiology of the pulmonary function they avoid the confounding with tuberculous cavities of transparent bubbles seen on the screen; they guard against erroneous induction of pneumothorax in parenchymatous lesions, when the presence of Koch bacilli cannot be demonstrated; they also influence the prognosis in pulmonary disorders of infants and young children, in whom the roentgenograms show cavitations.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Aug. 31, 1945.

Epidemic of Influenza

During the second half of July the number of cases of influenza began to mount sharply in Rio de Janeiro. Since July is midwinter in the Southern Hemisphere, it is the normal time for the high point in the curve of prevalence of influenza. As the reporting of cases of transmissible diseases is not well developed here, particularly in the case of common colds and influenza, the only foundation for the study of the incidence of the disease is the mortality. The annual death rate from influenza, computed only on the basis of the death certificates clearly stating that influenza was the cause of the death, varies normally, in Rio de Janeiro, between 35 and 55 per hundred thousand of population, reaching peaks of 65, 70 and even 80 per hundred thousand at intervals of two to four years. The health department made efforts to get more reports of cases, but a better picture of the outbreak has been obtained through the study of the absenteeism in schools, offices and factories. A sample of about 40,000 industrial and clerical workers of all the districts of the city has shown that the rate of absenteeism in the offices and factories included in the sample rose from the normal of about 3 to 4 per cent to 7.97, 8.64, 7.09 and 8.32 respectively in the first four days of August (average percentage of 8.01 for the four days which corresponded to the peak of the curve of absenteeism), then slowly began to decline. At the end of August the percentage of absences was still at the relatively abnormal level of more than 5. A similar, but larger, sample (about 80,000 individuals) formed with children of the primary and high schools has shown the same condition, the only difference being that the highest percentage of absences was registered about the 7th or 8th of August. The death rate from influenza averaged 51 per hundred thousand during

the months of June and July; it began to rise in the last week of July (99 per hundred thousand) and then continued, rapidly reaching 165 and 187 per hundred thousand, respectively, in the first and second weeks of the month, which corresponded to the peak of mortality.

Hospital News

A small but modern hospital has been opened at Barra do Garças, state of Goyaz. The event is particularly noteworthy because the hospital is located in a backward section of the country, where the federal government is spending important sums of money, through the organization known as the Central Brazil Foundation, in a program to improve the general condition of the people.

The city of Rio de Janeiro has recently acquired a plot of land to increase the area of the Fernando Magalhães Maternity Hospital, which bears the name of the late professor of obstetrics of the university of this city, who was one of the leading practitioners of the specialty. This will permit the enlargement of the maternity, which serves a densely populated section of the suburbs of the city. The hospital has at present 50 beds.

The city of São Paulo has acquired a plot of land of 3,288 square meters (3,611 square yards) and transferred it to the São Paulo Association to Combat Cancer, which immediately will begin the construction of a cancer hospital.

The Division of Hospital Organization of the National Department of Health has published a booklet under the title History and Evolution of Hospitals, which is the first of a series to be distributed free, as a contribution to improve the hospital situation in Brazil. The booklet has been written by Dr. Ernesto de Souza Campos, professor at the São Paulo University, who is considered in Brazil an authority on the subject of hospitals. Dr. Campos stayed for several years in the United States and has also visited several hospitals in Great Britain, France and Germany.

A modern and well equipped tuberculosis hospital with 350 beds will be dedicated on August 4 in the borough of Fonseca of the city of Niterói (population 150,000), capital of the state of Rio de Janeiro, close to the Federal District (city of Rio de Janeiro). The institution will be known as the Azevedo Lima Hospital, to honor a great phthisiologist native of the state of Rio de Janeiro. There are at present in Niterói an average of 320 annual deaths from tuberculosis per hundred thousand of population.

Death of Paulo Cesar de Andrade

Dr. Paulo Cesar de Andrade, one of the most famous surgeons of Brazil and the leader of surgery in Rio de Janeiro, died a few days ago at the age of 51, the victim of a car accident. Dr. Andrade was also the medical superintendent of the Misericórdia Hospital and director of a center of post-graduate teaching at the hospital, the foundation of which was reported in THE JOURNAL, January 27, page 240.

Marriages

DAVID WENTWORTH BARTON, Troy, N. Y., to Miss Liliás Howland Swift of Princeton, N. J., July 14.

HENRY A. RUSCH JR., Centre Island, N. Y., to Miss Frances May Williams of Westfield, N. J., July 27.

MATTHEW A. STROUP, Cherryville, N. C., to DR. FRANCES P. SHAW of Oxford, Miss., June 11.

JOHN TRENTON TUCKER JR., Fort Worth, Texas, to Miss Dorothy Dee Hill of Dallas, June 2.

MARVIN DALE SMITH, Clinton, Miss., to Miss Mary Eleanor Gower of Grifton, N. C., July 8.

NINO A. BOLOGNA, Shaw, Miss., to Miss Betty Rowlett of Sweetwater, Texas, July 25.

JACK LEE FOSTER, St. Louis, to Miss Charlotte Smith of Cairo, Ill., June 30.

Deaths

Thomas Darlington, New York; College of Physicians and Surgeons, New York, 1880; born in Brooklyn Sept. 24, 1858; member of the American Medical Association, American Clinical and Climatological Association, New York Academy of Medicine, Society of Medical Jurisprudence, Harvey Society and the Physicians Mutual Aid Association; retired member of the Medical Society of the State of New York; fellow of the American Association for the Advancement of Science and the New York Academy of Science; served as vice president of the Greater New York Medical Association, National Institute of Social Science and the American Association for Promoting Hygiene and Public Baths; for three years surgeon to the Copper Queen Consolidated Mining Company and the Arizona and Southwestern Railroad Company with headquarters in Bisbee, Ariz.; served on the school board of the Bronx, on the visiting staff of St. John's Hospital in Yonkers, New York Foundling, French Seton and Fordham hospitals; medical editor of the *New York Mail and Express* from 1891 to 1893; health commissioner and president of the board of the city of New York from 1904 to 1910; in 1930 made commissioner emeritus; member of the New York State Workmen's Compensation Commission, 1914-1915; trustee and first vice president of the Metropolitan Savings Bank; director of the Morris Plan Bank; one of the fourteen executive members of the Congress of Physicians and Surgeons from 1907 to 1939; major, medical corps, U. S. Army, during World War I; served as professor of anatomy, principles of surgery, pathology and hygiene at the New York College of Dentistry, of which he had been a trustee, director and treasurer; formerly lecturer on industrial hygiene at the Stevens Institute of Technology and Fordham University, and sanitary engineer for the city department of health; for two years chairman of the Democratic County Committee; in 1924 received the honorary degree of doctor of literature from Juniata (Pa.) College; died at his summer camp, Burnt Hope, about 16 miles from Port Jervis, August 23, aged 86.

Sylvester Jacob Goodman @ Columbus, Ohio; Jefferson Medical College, Philadelphia, 1900; born in Uhrichsville, Ohio, Oct. 28, 1876; also a pharmacist; specialist certified by the American Board of Obstetrics and Gynecology, Inc.; in 1928 served as president of the Columbus Academy of Medicine; formerly councilor of the Tenth District of the Ohio State Medical Association, serving it as secretary from 1924 to 1934; president of the Columbus Obstetric Society; one of the founders of the Columbus Medical Bureau and a member of its original board of trustees; honorary fellow of the American Association of Obstetricians, Gynecologists and Abdominal Surgeons; fellow of the American College of Surgeons; formerly on the faculty of the Starling Medical College; served overseas during World War I; on the staffs of the White Cross Hospital, Institution for the Feeble-minded and St. Ann's Maternity Hospital; member of the surgical staff and director, obstetric department, Grant Hospital, where he died July 5, aged 68, of coronary thrombosis.

Alexander Hamilton Stewart @ Harrisburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1907; born in Plumville, Pa., July 22, 1880; in 1939 appointed deputy secretary of health and in 1941 acting secretary and in 1942 secretary of the Pennsylvania Department of Health; chairman of the advisory health board of the state of Pennsylvania; member of the House of Delegates of the American Medical Association in 1942, 1943 and 1944; served for ten years as secretary of the Indiana County Medical Society, of which he had been president for two terms of five years each and as trustee and councilor representing the Ninth District of the Medical Society of the State of Pennsylvania; at one time coroner and medical director of Indiana County; fellow of the American College of Physicians; from 1937 to 1940 chairman of the Indiana County Republican Committee; served as physician for the Pennsylvania Railroad and the Baltimore and Ohio Railroad; died July 31, aged 65, of acute myocardial infarction.

David Carl Farnsworth, San Fernando, Calif.; University of Southern California College of Medicine, Los Angeles, 1906; born June 5, 1882; served in France during World War I; entered the U. S. Public Health Service Reserve in 1920 as a surgeon; served as general inspector the following year with headquarters in Denver and San Antonio and clinical director of the Veterans Administration Facility in Houston; later assistant medical officer in charge of the Veterans Administration Facility in Legion, Texas, and chief of the tuberculosis division,

Central Office, Washington, D. C.; at the time of his death manager of the Veterans Administration Facility in San Fernando; died July 21, aged 63, of coronary thrombosis.

William J. Seymour @ Detroit; Detroit College of Medicine, 1903; born in Detroit Sept. 30, 1878; served on the faculty of his alma mater; fellow of the American College of Surgeons; for twelve years a member of the welfare commission; for many years on the staffs of the Receiving, Providence and St. Mary's hospitals; many years ago organized the medical and surgical services at the Eloise Hospital in Eloise, Mich.; the William J. Seymour Hospital in Eloise was named for him; in charge of Michigan's first public cancer clinic in Detroit in 1932; received the honorary degree of doctor of laws from the University of Detroit in 1933; died August 4, aged 66, of coronary thrombosis.

Jay Weir Grissinger @ Colonel, U. S. Army, retired, Harrisburg, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1898; Army Medical School in 1903 and the Army War College in 1920; born Aug. 22, 1875; entered the army as an assistant surgeon in 1902; promoted through the various grades to that of colonel on June 24, 1928; surgeon for the second corps area; held the Distinguished Service Medal; retired August 31, 1939; served during World War I; fellow of the American College of Surgeons; died in the Walter Reed General Hospital, Washington, D. C., August 8, aged 69, of hypertensive cardiovascular disease and cerebral infarction.

John Alexander Steward @ Chattanooga, Tenn.; University of Pennsylvania School of Medicine, Philadelphia, 1926; born in Chattanooga, Tenn., Aug. 6, 1897; fellow of the American College of Surgeons; interned at the Robert Packer Hospital in Sayre, Pa.; fellow in surgery at the Mayo Foundation in Rochester, Minn., from 1927 to 1932; served as chief of staff of the Pine Breeze Sanatorium and the Erlanger Hospital; served overseas during World War I; a major in the medical corps, Army of the United States, from September 1942 to December 1944, when he retired because of ill health; died in St. Mary's Hospital, Tucson, Ariz., July 7, aged 47, of cardiac failure.

Walter Black Rogers @ Cleveland; Johns Hopkins University School of Medicine, Baltimore, 1910; born in Waynesburg, Pa., in 1883; assistant clinical professor of surgery at the Western Reserve University School of Medicine; served in France with the Lakeside Unit during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; member of the Cleveland Medical Library Association; for many years on the staff of the Lakeside Hospital; died in the Leonard C. Hanna House-University Hospitals, July 12, aged 61, of embolism in pulmonary cavity following an operation.

Lawrence C. Ingram, Orlando, Fla.; Keokuk Medical College, College of Physicians and Surgeons, 1903; born in Perry Ill., in 1872; member of the American Medical Association and in 1932 of the House of Delegates; member of the Southeastern Surgical Congress and the American Academy of Ophthalmology and Otolaryngology; fellow of the American College of Surgeons; specialist certified by the American Board of Otolaryngology; past president of the Wabasha County Medical Society; on the staff of the Orange General Hospital; died in a hospital at Lake City, Minn., July 2, aged 72, of Hodgkin's disease.

Mary Caroline Abney-Squillace, Richland, Wash.; Washington University School of Medicine, St. Louis, 1935; interned at Hospital of the Woman's Medical College of Pennsylvania in Philadelphia and the Bellevue Hospital in New York; served a residency at the Brandywine Sanatorium in Marshallton, Del.; at one time joined the staff of Barnes Hospital in St. Louis as administrative assistant to the superintendent; died May 20, aged 33.

Herman R. Biersdorf, Portland, Ore.; University of Oregon Medical School, Portland, 1896; member of the American Medical Association; life member of the Oregon State Medical Society; died June 1, aged 72, of coronary occlusion.

Herman A. H. Bouman @ Minneapolis; University of Minnesota College of Medicine and Surgery, Minneapolis, 1897; at one time on the faculty of his alma mater; fellow of the American College of Surgeons; chairman of the board of directors of St. Andrew's Hospital and an honorary member of the staff of Northwestern Hospital; died June 18, aged 75, of coronary occlusion.

Isidor Eckert, New York; Baltimore Medical College, 1908; died April 6, aged 58.

Samuel Jesse Goldfarb ® New York; Columbia University College of Physicians and Surgeons, New York, 1905; for many years on the staff of the Mount Sinai Hospital; died June 27, aged 64.

Charlotte E. Goodman, Mount Pleasant, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1893; for many years associated with the State Hospital in Harrisburg; in 1943 awarded a citation by her alma mater for being a fifty year graduate; died June 12, aged 84, of exhaustion due to arteriosclerosis and valvular heart disease.

Edward Andrew Grice, Epps, La.; Memphis (Tenn.) Hospital Medical College, 1908; member of the parish school board and health unit; died June 20, aged 61.

Joseph Lowery Johnson, Columbus, Ohio; Howard University College of Medicine, Washington, D. C., 1902; formerly minister to Liberia, representing that country at the Versailles Peace Conference; past president of the board of trustees of Wilberforce University; at one time special investigator for the United States Pension Bureau; died July 18, aged 72.

Patrick Eugene Keffe, Sioux City, Iowa; Jefferson Medical College of Philadelphia, 1910; member of the American Medical Association; died in Ann Arbor, Mich., June 8, aged 59.

Irene Amanda Tognazzini Kenny, Jersey City, N. J.; Stanford University School of Medicine, San Francisco, 1916; in charge of clinics and director of the outpatient department of the Jersey City Medical Center, where she died April 25, aged 58, of coronary thrombosis following a cholecystectomy.

Louis Albert Kirshner, Philadelphia; Medico-Chirurgical College of Philadelphia, 1909; member of the American Medical Association; associated with Mount Sinai Hospital; died June 17, aged 60.

Thomas Leonard Lamkin, Clinton, Ky.; Barnes Medical College, St. Louis, 1899; member of the American Medical Association; also a lawyer; for eight years county attorney; died May 26, aged 72.

James Everard Massey ® Rock Hill, S. C.; Medical College of the State of South Carolina, Charleston, 1899; formerly state senator; honorary member of the South Carolina Medical Association; served as a member of the city board of health and of the teaching staff of the York County Hospital, where he died July 14, aged 70, of heart disease.

William Lester Mathews, Winder, Ga.; Atlanta College of Physicians and Surgeons, 1913; member of the American Medical Association; served overseas during World War I; served as physician in charge of the Barrow County Health Department; a member of the county board of education; the Mathews School was named for him; an examiner for the Selective Service Board; surgeon for the Seaboard Railway; served as president of the Alumni Association of Emory University School of Medicine; died May 4, aged 58.

William Fredrich Mayer-Hermann, New York; Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin, Prussia, Germany, 1914; member of the American Medical Association; died in the Sydenham Hospital June 13, aged 54.

Olin Kingsley McGarrah, Altoona, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1895; died June 6, aged 74.

Paul Scott Miller, Grand Rapids, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1905; chief of staff of D. A. Blodgett Home for Children for many years; died in the Blodgett Memorial Hospital June 13, aged 64.

Samuel Nempzoff, Philadelphia; Temple University School of Medicine, Philadelphia, 1935; on the staff of the Northern Liberties Hospital; died June 30, aged 34.

Ralph Henry Newcomb, Upper Lake, Calif.; University of Southern California College of Medicine, Los Angeles, 1908; died in June, aged 61.

Clarence S. Ordway ® Toledo, Ohio; Baltimore Medical College, 1902; founder and managing director of the East Side Hospital; died April 27, aged 71.

John David Rudisill ® Lenoir, N. C.; University of Maryland School of Medicine, Baltimore, 1922; fellow of the American College of Surgeons; served during World War I; examining physician for the county draft board during World War II; recently appointed as a member of the North Carolina Board of Conservation and Development; physician in charge of the Caldwell Hospital; surgeon, Watauga Hospital, Boone, and the Blowing Rock Hospital, Blowing Rock; surgeon to the Southern Railway; died in Edgemont July 28, aged 51.

Samuel D. G. Scruggs, Memphis, Tenn.; Kentucky School of Medicine, Louisville, 1886; died June 27, aged 95.

John Albro Sipher, Norwalk, Ohio; Western Reserve University Medical Department, Cleveland, 1903; member of the American Medical Association; past president of the Huron County Medical Society; served during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; for many years served on the school board; died June 4, aged 71.

Charles Burr Sitgreaves, Pemberton, N. J.; Baltimore Medical College, 1902; died May 24, aged 73, of lymphatic leukemia and diabetes mellitus.

George Edward Owen Leo Smith, Hoosick Falls, N. Y.; Albany Medical College, 1918; member of the American Medical Association; village health officer and school physician; served during World War I; died June 18, aged 50, of coronary occlusion.

Asa Bertrand Starbuck, Dallas, Ore.; University of Oregon Medical School, Portland, 1906; chairman of the Polk County chapter of the American Red Cross; member of the school board and city council; county health officer; on the staff of the Dallas Hospital; died June 8, aged 69, of coronary heart disease.

Albert Mason Stevens, Kaneohe, Hawaii; Columbia University College of Physicians and Surgeons, New York, 1915; served during World War I; died August 6, aged 61.

Eusebius J. Summers, Belva, W. Va.; College of Physicians and Surgeons, Baltimore, 1908; formerly a lawyer; died May 21, aged 72.

Clarence Irouth Thomas ® Guthrie Center, Iowa; State University of Iowa College of Medicine, Iowa City, 1905; died May 28, aged 63, of coronary thrombosis.

Alonzo Clinton Ward, Osceola, Mo.; Kentucky School of Medicine, Louisville, 1884; died May 28, aged 89, of cerebral hemorrhage.

HARRY M. LEVIN, Surgeon,
U. S. P. H. S. (R) 1903-1945

PUBLIC HEALTH SERVICE

Harry M. Levin, Surgeon, U. S. Public Health Service Reserve, Malden, Mass.; born in Baltimore, Sept. 7, 1903; College of Physicians and Surgeons, Boston, 1933; interned, Christ Hospital, Jersey City, N. J., and Prospect Heights Hospital in Brooklyn; served as medical consultant and sanitary supervisor to firms in Malden; member of the American Medical Association; commissioned in the Public Health Service Reserve in

February 1943; first assigned to stations on the West Coast and since September 1944 had been on sea duty in the South Pacific with the U. S. Coast Guard; shortly before his death was promoted to the rank of surgeon; medical officer on the U. S. S. *Serpis*, which was destroyed by enemy action in January at Guadalcanal; aged 41; reported missing January 29; declared killed in action by the Navy Department.

Miscellany

ADDRESS BY SAMUEL GOMPERS, PRESIDENT AMERICAN FEDERATION OF LABOR¹

Delivered in Washington, D. C., Dec. 5, 1916

One great, harmonious chord has been sounded since the opening of this meeting, and under such circumstances it is not a pleasant duty to sound a discord. Yet such a part I have frequently felt myself called upon to play.

For more than half a century out of my sixty-six years of life I have been concerned in the effort to try to bring light and a greater degree of happiness into the lives and the work of my fellow men, and particularly of my fellow workers. I doubt if there be any one whose life is more attuned to the misery and the suffering of any one of my fellows than mine. With me it is the thought not only of helping to assuage immediate want or suffering but of maintaining the opportunities of men to struggle for right and for justice.

There has never yet come down from any government any substantial improvement in the conditions of the masses of the people, unless it found its own initiative in the mind, the heart and the courage of the people. Take from the people of our country the source of initiative and the opportunity to aspire and to struggle in order that that aspiration may become a reality, and, though you couch your action in any sympathetic terms, it will fail of its purpose and be the undoing of the vital forces that go to make up a virile people. Look over all the world where you will and see those governments where the features of compulsory benevolence have been established, and you will find the initiative taken from the hearts of the people.

There are certain species of compulsory social insurance that by their mere statement carry with them the conviction of their self-evident necessity and justice, into which the element of depriving the people of rights cannot enter—such as workmen's compensation and old age pensions. But when compulsory health insurance and compulsory unemployment insurance are proposed, the question arises at once, What are the conditions and regulations to be imposed by the government to regulate the conduct of the supposed beneficiaries?

By reason of the many duties devolving on me I have not had the opportunity to prepare a paper. I have made some memoranda, and I ask your indulgence to present thoughts which press upon me in the best way I can within the limit of time set for these proceedings.

The highest standards in the lives of the workers have been secured by the development, the organization and the exercise of the economic power of the workers. Although this economic power is superficially indirect, it is in reality the most potent and the most direct social insurance of the workers. It is the only agency that can readily guarantee to the workers protection against the results of the eventualities of life and give them a feeling of security.

There is more voluntary social insurance among the workers in the United States than in any other country in the world.

The organization of labor, which has secured reductions in the hours of their daily toil, which has secured higher wages and better standards of life, which has secured safety and sanitation, has done more to eliminate poverty and misery and unemployment and sickness than all other agencies of government and private individuals combined.

The trade-union of which I am a member and to which I owe my primary membership, in less than twenty-five years, as shown by absolutely accurate data, has reduced the sickness of

its membership to a marked degree. It has lengthened the lives of the members of that craft on an average more than sixteen years. What is true of that organization is true to a greater or less degree of every other trade-union in America.

The organizations of labor provide social insurance in cases of sickness or unemployment far too little to be true to their mission, far too narrow to suit my impatient spirit; but the willingness to fly from the ills we bear to those of which we know not is quite too general among men who are well meaning, yet who are theorists, or who desire to indulge themselves in a fad that involves grave consequences not only to the workers themselves but to the fundamental principles of freedom.

Social insurance cannot even undertake to remove or prevent poverty. It is not fundamental and does not get at the causes of social injustice. The only agency that does get at the cause of poverty is the organized labor movement.

Social insurance, in its various phases of sickness insurance, unemployment insurance and death benefits, provides the means for tiding over an emergency.

The labor movement aims at constructive results—higher wages, which mean better living for the worker and those dependent upon him, better homes, better clothes, better food; and shorter hours of work, which means relief from overfatigue and time for recuperation, workers with better physical development and with sustained producing power. Better physical development is in itself an insurance against illness and a certain degree of unemployment. The short hour workmen, with higher wages, become better citizens, better able to take care of themselves.

Then again, the first step in establishing compulsory social insurance is to divide people into groups, those eligible for benefits and those considered capable of caring for themselves. The division is based on earning capacity. This governmental regulation must tend to fix the citizens of the country into classes, and a long-established insurance system would tend to make those classes rigid.

Governmental power grows upon that on which it feeds. Give an agency power, and it at once tries to reach out after more. Its effectiveness depends on increasing power. This has been demonstrated by the experience of the railroad workers in the recent enactment of the Adamson law. When Congress exercised the right to establish eight hours for railroad men, it also considered a complete program for regulating railroad workers, which culminated in the effort to take from them the right to quit work, and conscription providing for compulsory service.

Recently a gentleman of the highest standing stated to me that during the time he was in Germany, and in a position to know, German workmen came to him seeking aid to get out of that country to the United States. They told him that by reason of the taxes which they were compelled to pay into compulsory social insurance schemes, they had no money left except for absolute necessities of life and were unable to secure sufficient funds to come to the United States even in the steerage. He said to me further that in Germany, where compulsory social insurance has been more extensively worked out than in any other country, the workmen of that country, by reason of their property interests in compulsory social insurance, have been compelled to remain in Germany and work under circumstances, wages, hours and conditions of employment which forced them to endure conditions below standards of a living wage.

Is it not discernible that the payments required of workmen for this compulsory social insurance interfere very materially with mobility of labor and constitute a very effectual barrier to the workers' determining their whole lives?

It seems to me that what we in America will have to do is to proceed on grounds that shall bring not only social insurance of a practically advantageous character but that shall help

1. Published in the Bulletin of the U. S. Bureau of Statistics, No. 212, page 845.

to develop individuality and personality and character and help to recognize the real struggle of the masses of the people, to encourage them in their struggle so that they may have the higher and the better opportunity for self development. What we should aim to do is to encourage voluntary associated effort of free individuals for their social insurance.

Industrial freedom exists only when and where wage earners have complete control over their labor power. To delegate control over their labor power to an outside agency takes away from the economic power of those wage earners and creates another agency for power. Whoever has control of this new agency acquires some degree of control over the worker. There is nothing to guarantee control over that agency to employees. It may also be controlled by employers. In other words, giving the government control over industrial relations creates a fulcrum which means great power for an unknown user.

The introduction of compulsory social insurance in cases of sickness, or compulsory social insurance in cases of unemployment, means that the workers must be subject to examinations, investigations, regulations and limitations. Their activities must be regulated in accordance with the standards set by governmental agencies. To that we shall not stand idly by and give our assent.

At this moment the peoples of the European countries engaged in this titanic, brutal struggle are organized, and they exhibit a virility and a ferocity unknown in the history of the world. The intensity of their labor, the intensity of their activity, is not a good standard by which anything now can be judged; but in our industrial, commercial, political and social fabric, the fabric of the United States, there has never been a people in the history of the world so virile in intellectuality, in industry, in intensity, as were and are our own, much misrepresented even though they be.

Men and women, I trust I may not be sounding my warnings on the empty air. I hope that they may find a lodgment in the minds and the hearts of my countrymen. I bid you have a care in all these attempts to regulate the personal relations and the normal personal activities of the citizenship of our country ere it be too late.

There is in the minds of many an absence of understanding of the fundamental essentials of freedom. They talk freedom and yet would have bound upon their wrists the gyves that would tie them to everlasting bondage. And no matter how sympathetic or humanitarian is the gloss over the plan and the scheme, I again bid you beware. We know not when or how this great struggle going on in Europe will terminate, or what it shall mean for the future of those countries; but at least let the people of the United States hold their liberties in their own hands, for it may come to pass that our America, the America whose institutions and ideals we so much revere, may be the one nation to hold the beacon light of freedom aloft and thus aid in relighting the torch, rekindling the heart flame of the world's liberty.

Last Saturday night I witnessed a sight in the harbor of New York City that thrilled me anew in the hope of the perpetuity of the principles on which our republic is based. I saw there the Statue of Liberty, and at the pressing of a button by the President of the United States the whole structure of that wonderful image was illumined and bathed with a light that could not but inspire the meanest of all. In the hand of the Statue of Liberty was a new construction, so that the flame in that torch might be visible to all who might see.

My hope is that we shall be enabled to sing, as we hope that the generations who follow us shall be enabled to sing—

My country, 'tis of thee,
Sweet land of liberty.

For a mess of pottage, under the pretense of compulsory social insurance, let us not voluntarily surrender the fundamental principles of liberty and freedom, the hope of the Republic of the United States, the leader and teacher to the world of the significance of this great anthem chorus of humanity—liberty!

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, Sept. 15, page 232.

BOARDS OF MEDICAL EXAMINERS

ALABAMA: Mar. 19-21. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.

ALASKA: Juneau, September. Sec., Dr. W. M. Whitehead, Box 561, Juneau.

ARIZONA: * Phoenix, Oct. 2-3. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

ARKANSAS: * Eclectic. Little Rock, Nov. 8. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.

CALIFORNIA: Oral. San Francisco, Nov. 11. Written. Sacramento, Oct. 15-18. Sec., Dr. Frederick N. Scatena, 1020 N St., Sacramento 14.

CONNECTICUT: * Medical. Examination. Hartford, Nov. 13-14. Endorsement. Hartford, Nov. 27. Sec. to the Board, Dr. Creighton Barker, 258 Church St., New Haven. Homeopathic. Derby, Nov. 13-14. Sec., Dr. J. H. Evans, 1488 Chapel St., New Haven.

FLORIDA: * Jacksonville, Nov. 26-27. Sec., Dr. Harold D. VanSchaick, 2736 S. W. Seventh Ave., Miami 36.

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Conclusion of Medical Advisory Board Unsupported by Facts Not Binding on Industrial Commission.—While lifting a 70 pound ladder in the course of his employment, April 13, 1942, Tashner lost his balance and in an effort to prevent the ladder from falling on a near-by window he severely wrenched or strained his back, the immediate effect being a sharp pain in the lower part of his back. He completed work that day with considerable difficulty. Thereafter he was bedridden for some time. Admittedly, since the industrial accident he has not been able to perform any manual labor which entailed in any way the use of the back. For the first ten months of 1943 he was under the care and observation of the physicians whose services were paid for by the Industrial Commission of Arizona. The only objective symptoms discovered were a very narrow disk space between the vertebral body and the base of the sacrum, causing them to be almost in contact, and a condition described as fascitis, an inflammation of the tissues covering the left buttock muscles of a cordlike character. Apparently, either of these conditions could have resulted from the trauma and strain incident to the injury. The subjective symptoms were continual pain and tenderness in the region of the lower vertebrae on the left side and the left buttock. Various tests applied by the physicians employed by the commission ruled out any possibility that Tashner's condition was the result of any disease, infection or constitutional or postural defect. Concededly he was not malingering. Significantly, prior to the industrial accident he had never suffered from backache, sustained injury or lost time.

On Nov. 8, 1943 the medical advisory board provided for by the workmen's compensation act of Arizona examined the workman and filed a report finding the medical facts substantially as stated. The board, however, concluded that in its opinion "any disability he may have suffered as the result of his accident has terminated." Based on the opinion of the board, the Industrial Commission ceased payment to him of compensation, which he had been receiving since August 1942. The commission about a year later granted a rehearing to the workman on his claim that his disability still persisted. At the hearing he produced witnesses who testified that from the period of the medical board's findings until the date of the rehearing he continued totally disabled. Reports of the commission's own investigators confirmed this fact. The workman, however, produced no medical expert witnesses to report on his condition at the hearing, allegedly because he was without means to employ them. Nevertheless as a result of the rehearing the commission confirmed its order of the previous year, finding that the workman had no disability as a result of his injury from and after the report of the medical advisory board in November 1943. The workman then brought certiorari to the Supreme Court of Arizona.

This court, said the Supreme Court, has uniformly held that, where an order or finding of the Industrial Commission is based on reasonable evidence, it will be upheld. The only evidence in the record which supports the commission's order is the conclusion of the medical advisory board, as made on Nov. 8, 1943. The sole question is, does this conclusion afford reasonable evidence to support the award? If it does not, the case must be reversed and the order set aside. It is for the Industrial Commission, not the medical advisory board, to determine whether or not disability has ceased. The commission should, and must, give due weight and consideration to the opinion of the medical board, but it is not bound by its conclusions, particularly where the conclusions are wholly unsupported by the actual facts or,

as here, contrary to the medical history and findings. It is the medical findings rather than the conclusion which constitute evidence. Obviously a conclusion or opinion which is counter to the actual facts or findings, and which on the face of the record is illogical and without support, cannot be treated as reasonable evidence. We have carefully read the report of the medical advisory board. Various examinations made by competent physicians disclose that the workman's disablement is not the result of any disease, infection or other natural defect. There was no improvement in his condition; he had the same tenderness; the condition described as fascitis still existed. There is no showing that the narrowed disk space between the vertebral body and the base of the sacrum had become normal. The petitioner was still disabled. There is nothing to indicate from the record that the workman's condition was from any cause other than that which might well have resulted from his industrial injury. The report is replete with showings that the workman's condition was not the result of any disease or other like cause, and there is no finding in the report that his condition was not caused by, or was not the result of, the injury. From the medical advisory board's own report we can find no support for its conclusion and therefore hold that no reasonable evidence exists in support of the findings of the Industrial Commission.

The Supreme Court accordingly set aside the award of the Industrial Commission and in effect ordered the continuance of compensation payments to the workman.—*Tashner v. Industrial Commission*, 157 P. (2d) 608 (Ariz., 1945).

Malpractice: Dentists; Extracted Tooth Lodged in Bronchus.—The defendant dentist, after administering "gas and ether," extracted sixteen of the plaintiff's teeth, April 5, 1940. When the patient "came out of the ether" she was nauseated and bled profusely. She returned home, remaining in bed for several days. She had a "bad" cough, suffered a constant pain in the chest and had difficulty in breathing. This condition persisted, and early in May her attending physician sent her to a hospital for roentgenographic examination; but nothing was discovered at that time to account for her condition. For the next fifteen months her chest was sore and she "suffered dry coughing spells and raising of blood" and from time to time she went to a hospital for examination, treatment and the taking of roentgenograms. During a "coughing spell" in July 1941 she disorged a tooth fragment. Her health immediately began to improve and the pain in her chest disappeared. A review of her "x-ray record" revealed the presence of a tooth fragment in the left lower bronchus. Subsequently she instituted action against the dentist, alleging negligence on his part in permitting the extracted tooth in question "to fall down her throat." At the close of the patient's evidence the trial court directed a verdict in favor of the dentist, and the plaintiff brought exceptions to the Supreme Judicial Court of Massachusetts, Middlesex.

We believe, said the Supreme Judicial Court, that the action of the trial court in directing a verdict in favor of the dentist was error. From the evidence presented, the jury would have been warranted in finding that one of the plaintiff's teeth became lodged in her bronchus and that it got there through the negligence of the defendant while extracting sixteen of her teeth April 5, 1940. This is not a case in which a finding of negligence must rest on mere conjecture. We have not overlooked the fact that the plaintiff offered no expert evidence on the issue of the defendant's negligence. Ordinarily a jury will not be permitted without the aid of expert evidence to determine whether the conduct of the dentist or physician is a breach of the duty owed to a patient. But, although exceptional, the facts in a malpractice case may show that jurymen out of their common knowledge and experience are able to pass on this question. We think that the present case comes within this class.

Accordingly the appellate court in effect reversed the action of the trial court and remanded the cause for further proceedings.—*Malone v. Bianchi*, 61 N. E. (2d) 1 (Mass., 1945).

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

*Note on Stability of Cold Hemagglutinins. L. A. Erf.—p. 210.

Cold Isohemagglutinins in Primary Atypical Pneumonia.—According to Platt and Ward, cold hemagglutination is generally recognized to be distinct from the better known isoagglutination reactions between the various human blood groups and subgroups. The pseudoagglutination seen in serums with elevated globulin and fibrinogen concentrations and the so-called Huebener-Thomsen phenomenon exhibited in erythrocytes that have been acted on by bacteria, whereupon they demonstrate the property of panagglutination, must also be placed in separate categories. Differing from the atypical warm agglutinins, which are produced by isoimmunization and which react strongly in vitro at 37 C. and which are practically inactive at 25 C., these cold agglutinins show agglutination at 20 C. or lower. The latter agglutinins are also often referred to as autoagglutinins, since they may agglutinate and hemolyze the individual's own corpuscles when the temperature is reduced. The phenomenon occurs in primary atypical pneumonia, complicated mumps, scarlet fever, tonsillitis, measles, Oroya fever, lobar pneumonia, rheumatic heart disease, subacute bacterial endocarditis, kala-azar, chronic tuberculosis, hemolytic anemia, paroxysmal hemoglobinuria, leukemia, pernicious anemia, lymphoblastoma, thrombocytopenic purpura, trypanosomiasis, relapsing fever, hepatic cirrhosis, Raynaud's syndrome, acro-gangrene, pregnancy, venous thrombosis, pulmonary embolism, bronchogenic carcinoma and carcinoma of the ileum and following splenectomy. The most significant and consistent occurrence of cold agglutination is that seen in the second week of the majority of cases of primary atypical pneumonia. The authors' patient, a woman with primary atypical pneumonia associated with cold isohemagglutinins, hemolytic anemia and multiple thromboses, required operative amputation for pedal gangrene. Although the reaction *per se* cannot be said to have any significant specificity, it is of some value in confirming a previous diagnosis of primary atypical pneumonia.

Stability of Cold Hemagglutinins.—Erf studied 2 serums, both of which contained cold agglutinins in exceptionally high titer. The titer of cold agglutinins of the serum of 1 patient was 1:250,000 in the fresh fluid state, 1:16 after thirty days' storage at ice box temperature and 1:8 after fourteen months' storage in the frozen state. Another sample of the serum, which was dried, retained a titer of 1:64 after fourteen months' storage when restored to the isotonic state and 1:256 when restored to two times isotonicity. The cold agglutinins disappeared from

the blood of the patient six weeks after the onset of the viral pneumonia. In the second patient the observations on the cold titer were similar to those in the first. This patient had nausea, vomiting and diarrhea of possible viral origin.

Rickets in Early Childhood and Skeletal Development in Adolescence.—A group of 10 children who in early childhood had shown evidence of severe rickets were reexamined in adolescence. These 10 subjects were selected by Dunham and Thoms because they were examples of the most severe and prolonged type of rickets occurring in early childhood and not because of any special abnormalities in adolescence. Six of the children were boys, and 4 were girls. On the basis of the pelvic roentgenograms these 10 children fall into two groups: 5 children who had rachitic pelvis in adolescence and 5 who had nonrachitic pelvis. Of the 5 adolescent children with rachitic pelvis 3 were more than 4 years of age when active rickets was diagnosed; of the 5 whose pelvis were normal 4 were less than 3 years of age when active rickets was diagnosed. Apparently, the older the child at the time when active rickets of a moderate or severe degree is present, the greater is the chance that the pelvis will show rachitic deformities in adolescence. Physical examination showed that all 10 children had in adolescence some deformity of the lower extremities. In the children who had had severe rickets in early childhood knock knees were associated more often with rachitic deformities of the pelvis than were bow legs. Severe or moderate deformities of the spine or of the lower extremities were found in early childhood as often in the group with normal pelvis in adolescence as in the group with rachitic pelvis. Differences in the two groups were found in the incidence of knock knees in early childhood: Of the 5 children with rachitic pelvis in adolescence 2 had had knock knees in early childhood and 2 had had bow legs. Of the 5 children with normal pelvis in adolescence none had had knock knees in early childhood. Observations suggest that if knock knees were present in early childhood the pelvis in adolescence is more likely to show the deformities of rickets than if bow legs were present in early childhood.

Abdominal Crises in Sickle Cell Anemia.—Tomlinson of the Gorgas Hospital in the Canal Zone describes a clinicopathologic picture of abdominal crises in 11 uncomplicated cases of sickle cell anemia. Four of the patients were dead on arrival at the hospital or died before they were seen by a physician. All but 3 of the patients were children less than 6 years of age, the 3 being 9, 11 and 18 years of age respectively. Of the

7 patients examined during life, 5 were in shock. The clinical picture was characterized by sudden onset of distress, pain, rigidity or tenderness in the abdomen usually accompanied by nausea and vomiting, occasional pain or tenderness in the muscles and bones, severe malaise, chill and fever; frequent jaundice, early, rapid peripheral vascular collapse with shock and central nervous system involvement. Clinical laboratory studies revealed severe normochromic anemias with an absolute increase in mononuclear cells; nucleated erythrocytes and sickled forms were an almost constant finding, and the icterus indexes were increased. Postmortem examinations revealed congestive and degenerative changes in the capillaries and small venules of the brain, pyramidal cell degeneration, glial proliferation and corpora amylacea. In the hearts there were hypertrophy, fatty changes, albuminous degeneration, edema and fragmentation of the myocardial fibers. The livers showed congestion and extensive phagocytosis of sickled erythrocytes by the reticuloendothelial cells, and the same findings were present in the lymph nodes. The spleens were enlarged in 8 of the 11 cases and showed congestion and "pooling," together with fibrosis of the capsule, trabeculae and reticular stroma. The clinical symptoms at the onset of abdominal crises in sickle cell anemia are remarkably similar to Wintrobe's description of the symptoms of rapid destruction of blood. It is felt that the symptoms are due at first to increases in the number of sickled cells and their removal from the circulation with rapidly developing shock. A possible explanation for the shock is that the anoxia accompanying anemias is increased in severity in sickle cell anemia, as sickled erythrocytes do not carry or are poor carriers of oxygen to the body tissues; the heart in severe anemia is weakened; sickled erythrocytes have a tendency to pack or jam in small capillaries; the capillary anoxia results in plasma loss, hemoconcentration and stagnation, and the stagnation removes available erythrocytes from the circulation, increasing circulatory failure and anoxia and perpetuating the vicious cycle of shock. Transfusions may greatly alter the clinical picture. Transfusions must not be given from persons showing the sickling trait.

Penicillin in Bronchial Asthma.—Leopold and Cooke present the histories of 2 patients with intractable continuous bronchial asthma. The first patient was given intramuscular injections of penicillin until a total of 1,375,000 units had been given, the daily dose being 100,000 units. The second patient was given the same daily dose for ten days. In the first patient, following treatment, there was complete remission of asthmatic symptoms for almost four months, although frequent examinations of the lungs during this time revealed the almost constant presence of sibilant rales. No such remission had occurred in the fifteen previous years. An acute upper respiratory infection produced the expected recurrence of asthma; its subsidence has been followed by subjective relief, although sibilant rales were usually present. In case 2, four months have elapsed with no subjective asthma. Twenty-five additional patients with intractable asthma have either been treated with penicillin very recently or are under treatment at the present time. Penicillin is not a panacea for all cases of asthma due to infection, for some patients have shown no improvement after penicillin therapy. It is possible that this drug may be helpful in treatment of two groups of asthmatic patients: those with both extrinsic and intrinsic asthma, provided the extrinsic factors are properly controlled, and those who have only intrinsic disease. It is possible that penicillin may be of value in that group of cases in which the bacteria recovered from the sputum or from the upper respiratory tract are shown to be sensitive to penicillin in vitro.

Tuberculosis a Military Problem.—According to Long, exclusion of tuberculosis from the Army in the first world war was carried out by physical examination. Auscultation of the chest was skilful and possibly superior in character to that practiced today. It was far inferior in the detection of tuberculosis to modern x-ray methods. While physical examination of the chest is an integral part of induction station examinations, maximum reliance is placed on the x-ray appearance. Nothing illustrates more clearly the value, and at the same time the limitations, of preinduction x-ray examinations than a comparison of the admission rates for tuberculosis in the first world war and in the present war. The rate in the war of 1914-1918 was approximately ten times that for the present war. It must not be assumed, however, that the difference is entirely due to improved methods of detection in the present war. Fewer cases, relatively, were to be excluded in the present war, for the incidence of tuberculosis in the general population at the present time is approximately one third of that prevailing in the period of the first world war. Cases developing in the United States Army in the present war for the most part represent extension from small areas of infiltrative tuberculosis not previously detected. Extension from scarred and calcified primary lesions has not been demonstrated. Statistics suggesting an increasing amount of exogenous infection overseas have been reported in the Canadian army, but indications are not yet at hand of a comparable situation in our army. The predominant type of tuberculosis occurring in our army is the chronic, ulcerative, pulmonary form. Acute forms are relatively rare, at least in the white race, and up to the present, while numerous advanced cases have been returned from overseas, indications are not evident that climate or any specific environment is a factor in the development of fulminating disease. Great progress has been made in evacuation of patients, particularly by air. All active tuberculosis is cause for discharge, but arrangements are in effect for preliminary treatment in the Army and indoctrination on the great importance of continuation of care after separation from the service and establishment of veteran's status.

Effect of Altitude on Air in Chest.—Civil aircraft usually fly at altitudes less than 10,000 feet above sea level, but higher altitudes may be occasioned by mountainous country or storms. The Bridges point out that exposure to lowered barometric pressures will cause expansion of abnormal accumulations of gas in the patient's chest, depending on the rigidity of the tissue walls enclosing the gas. The enclosing walls of uncomplicated intrapleural pneumothorax present the least resistance to gaseous expansion, because the elasticity of the lungs encourages their collapse. The hazard of reduced barometric pressure is magnified by increasing altitude, and the greater the amount of gas producing the pneumothorax the greater will be the collapse of

the lung. A patient carrying 1,000 cc. of intrapleural air at sea level will have the equivalent of 1,490 cc. at 10,000 feet and 2,120 cc. at 18,000 feet. With an increase in effective pneumothorax there can be a contralateral shift of the mediastinum and partial collapse of the opposite lung. It is apparent that pneumothorax which is tolerable for the patient at sea level could endanger his life at a high altitude. Pneumothorax complicated by mediastinal hernia or by visceroparietal adhesions offers the risk of increasing the hernia or rupturing the adhesions. The greater the tension of the adhesions, the more likely they are to rupture. A pulmonary cavity, unless communicating freely with a bronchus or possessing very rigid walls, could be expected to expand. Expansion of the cavity might rupture its walls, disseminate infective material or induce hemorrhage by severing vessels traversing the cavity. Expansion of gas producing mediastinal and subcutaneous emphysema could cause further dissection by emphysematous tissue when subjected to reduced pressure. The following conditions contraindicate air travel for patients with abnormal accumulations of air in the chest: (1) cyanosis or dyspnea, (2) recent hemoptysis, (3) visceroparietal adhesion, (4) mediastinal hernia, (5) mediastinal displacement, (6) pulmonary cavity containing fluid or with signs of intermittent bronchial communication or with closed bronchial communication, (7) mediastinal emphysema and (8) pulmonary emphysema with dyspnea. They believe that air travel should be restricted to those patients who would have no respiratory or circulatory distress and no physical discomfort if the abnormally accumulated air in the chest was doubled.

Denial of Blindness by Patients with Cerebral Disease.—Redlich and Dorsey observed 6 instances of denial of blindness over a period of eighteen months in a 600 bed hospital. Most examiners are reluctant to make any attempt to stress forcibly to the patient such a severe defect as blindness. All patients who present such a syndrome are deteriorated and have disturbances of retention and orientation, hallucinations and delusions. The syndrome of denial of their own blindness in the authors' patients was caused by diabetic retinopathy in 1 patient, by atrophy of the optic nerve in another, and by bilateral hemianopsia due to tumor or to vascular lesions in 4 patients. All patients had diffuse cerebral lesions. All showed intellectual deterioration: disorientation, severe impairment of recent memory and retention, and confabulation. The existence of bilateral focal lesions of the visual radiations or of the occipital visual areas leading to bilateral hemianopsia seems to play an important part in the pathogenesis of the syndrome. The interruptions of reverberating circuits between the thalamus and the sensory cortex constitute the most prominent etiologic factor.

Internal Derangements of Knee Joint.—Jaekle reports 190 arthroscopies of the knee joint performed in military personnel in the Station Hospital, Camp Roberts, Calif., within a two year period. An equal number of patients with affected knee joints were not operated on and have since been reclassified or discharged. Many of these patients had deranged joints before their entry into the service and had been advised by their own physicians not to have operations. The patient was taught exercises for the quadriceps muscle before the operation and was impressed with the idea that his cooperation was the deciding factor in a successful operation. Analysis of operative results in 155 cases of torn semilunar cartilages showed that lack of immobilization, early exercises and weight bearing give quicker return of function. Simple excision of bucket handle tears is sufficient, and in so-called complete excision a thin margin of cartilage should remain. One hundred and thirty-two men (85.16 per cent) have returned to duty on an average of twenty-five days following operation for injuries incurred from a few days to eleven years before. The results justify immediate operation because the total time lost from recurrence of injury will be considerably more with conservative treatment. The longer the torn cartilage remains the more likely it is that joint surfaces will become damaged and that a complete cure cannot be obtained. Hypertrophic fat pads are not generally recognized as a frequent derangement of the knee joint, but operation is warranted because of recurrences of symptoms and possible damage to the joint.

Treatment of Diphtheria Carriers with Penicillin.—Berman and Spitz applied penicillin locally to the nose and throat of a group of diphtheria carriers in an attempt to revert them quickly to a noncarrier status. A patient was not considered a carrier unless diphtheria organisms had been found in culture of the nasopharynx for a period of more than three weeks. In a group of diphtheria cases, 22 fell into this category. These were divided into a control and a treated group. The control group of 12 cases had had positive cultures for *Corynebacterium diphtheriae* for four weeks. The treated group of 10 patients likewise had been positive for four or five weeks. The penicillin was dissolved in isotonic solution of sodium chloride so that 1 cc. contained 500 Oxford units. By means of an ordinary nose dropper, 1 cc. of this solution was instilled into both nares four times each day for five days. Immediately after instillation another 1 cc. was sprayed with an atomizer onto the fauces and posterior wall of the pharynx. The total amount of penicillin used per patient throughout the five day course was 20,000 units. The control group of patients was treated with hot saline gargles four times daily. In the 10 treated cases the throat cultures became negative within the treatment period or on the first day after cessation of therapy. Seven of the 12 patients in the untreated group reverted to

negative within the fifth week. The remaining 5 continued to be positive for six to seven weeks, after which it was decided to treat them with penicillin. All of these cases became negative as in the treated group; that is, within the five days of therapy or on the first day thereafter.

Fenestration Operation for Deafness.—Several factors having to do with this operation will not be cleared up until enough cases have been amassed to allow for their proper evaluation. The oldest cases in which operation has been performed are now some six years since operation. In some of these the maintenance of improvement is remarkable. Martin sees no reason to suppose that the degeneration of the nerve will be halted by the operative procedure. This factor will have to await passage of time before it can be evaluated. If Gray's theory that the nerve change is primary and the bony change is trophic is correct, it will eventually prove that there will be no arrest of the disease by the operative procedure. As to the advantages of this procedure over wearing a hearing aid, those who have had a hearing aid and then obtained a successful fenestration result claim that there is no distortion of speech and that the selective amplification of speech over the attendant noises in everyday life returns as soon as their hearing improvement has become manifest after the operation. This amplification of incidental noises is one of the chief complaints against the hearing aids. The worse ear is usually operated on, and in the event of its loss through misadventure during the operation there is still a useful ear on which the hearing aid can be used.

Effect of Scopolamine on Airsickness.—A preventive and curative effect has long been ascribed to scopolamine in seasickness. The pharmacologic rationale for the use of scopolamine in motion sickness is based on its anticholinergic activity and its well recognized sedative and tranquilizing central effects, but the actual mode of action is unknown. In contrast to atropine, to which it is closely related, scopolamine in therapeutic doses produces little or no mydriasis, cycloplegia, tachycardia or suppression of salivation and sweating. These properties make scopolamine peculiarly adapted for use in aviation. Lilienthal investigated the effect of scopolamine hydrobromide on motion sickness in aircraft in a group of aviation cadets. These subjects were well suited to this study by virtue of their previous flight experience (approximately two hundred hours) and because they spent two thirds of these flights in nonpiloting duties, in which airsickness is more likely to develop. On 531 cadet flights, when no drug was administered, 40 cadets became

obviously airsick, an attack rate of 7.5 per cent. On 200 cadet flights, when 0.6 mg. of scopolamine was administered perorally thirty to sixty minutes before flight, only 1 man became airsick, an attack rate of 0.5 per cent. On 239 subsequent cadet flights each cadet was given a lactose placebo indistinguishable from the scopolamine. In this group 15 cadets became airsick, an attack rate of 6.3 per cent. Encouraging results were encountered in the prevention of airsickness in individual susceptible subjects. The author concludes that scopolamine hydrobromide in doses of 0.6 mg. administered perorally thirty to sixty minutes before flight is a potent preventive of airsickness with insignificant side effects.

Autokinetic Illusion in Night Flying.—Graybiel and Clark found that autokinesis is universally experienced by normal persons. The period of delay before the onset of movement is almost always short, averaging approximately nine seconds. The median duration of a movement in a particular direction is approximately ten seconds. Movement is observed about half of the time. The rate of movement is usually slow but may be rapid. The angular displacement for most movements is not great, but exceptionally a large displacement occurs. Movement is seen in all directions. Voluntary control, including suppression of movement, is limited. Although the illusory effect increases and decreases respectively with increase and decrease of the visual frame of reference, it is not readily abolished. Under relatively simple conditions in the laboratory, which simulate certain features of flying in formation at night, the subject is frequently confused. He cannot always tell when a particular movement of the target begins or ends and often cannot distinguish real from apparent movement. Autokinesis is readily observed under favorable conditions during formation flights at night and probably offers the explanation for some of the accidents that have occurred. Autokinesis is decreased by factors which improve the spatial localization of objects, by rapid relative movement of the target and by periodically withdrawing the attention from an object for at least ten seconds. If it is not feasible adequately to reduce autokinesis, help can come through a knowledge of its characteristics. All aviators and probably the operators of certain other means of transportation should be made aware of the characteristics of this phenomenon and of the practical means by which it can be reduced, namely (1) using some fixed object (for example, the framework of any opening or part) as a reference point, (2) periodically interrupting any steady fixation of a target light, and (3) in case of doubt regarding the reality of an observed movement, placing reliance on the instruments, if these conflict with the pilot's perceptions.

Active Pulmonary Tuberculosis and Decompression Sickness.—Barach and his associates found that 2 physicians developed active pulmonary tuberculosis during the course of repeated exposure to altitudes of 42,000 feet. This exposure did not produce the original disease. It is considered probable that previous lesions were quiescent but were reactivated by local trauma to the lung parenchyma produced when air or other gases expanded in or near a tubercle. It is thought that air might have become trapped in an area of tuberculous infiltration or that bubbles of gaseous nitrogen formed within the tubercle during exposure to a low pressure atmosphere. In the case of gases trapped in the lung, this would amount to an increase of 8.8 times the sea level volume at an altitude of 42,000 feet. Disruptive forces, such as expansion of gases and

greater pressure differentials, might result in the tearing and rupture of a tubercle with cavity formation and liberation of viable tubercle bacilli into uncontaminated areas of the lung. The dangers described are unlikely when personnel are exposed to altitudes less than 18,000 feet, as in commercial flying.

Glycol Vapor and Dust Control.—Puck and his associates report that the introduction of triethylene glycol vapor into the air plus the application of dust control measures, to the floors and bedclothes of streptococcus sore throat wards resulted in a reduction in the number of air borne beta hemolytic streptococci of 93 per cent when the wards were quiet and 97 per cent during bed making periods. The dust prevention treatment by itself lowered the streptococcus count by 86 per cent during bed making but not at all when the ward was quiet. However, when glycol vapor was introduced into a ward in which dust prevention was already in effect there resulted a further reduction of the residual streptococci present in the air during both quiet and bed making periods. Glycol vapor concentrations maintained at a level just below the fogging point were found to be as effective as supersaturated atmospheres. The authors believe that the combination of triethylene glycol vapor plus dust preventive treatment of floors and bedclothes offers a promising means of controlling air borne infection in hospital wards.

Domestic Mosquitoes and Transmission of Vivax Malaria of Foreign Origin.—Young and his associates say that in the fall of 1943 the Public Health Service in cooperation with the Army established the Imported Malaria Studies Program. The objectives were: 1. To determine the ability of the imported malaria to infect American anophelines and to be transmitted by them. 2. To gather information on the parasitology and other characteristics, and to distinguish, if possible, between strains. 3. To evaluate the findings and suggest their implications on control measures. This report is the first of a series resulting from these studies and includes work accomplished through Sept. 30, 1944. On the basis of the evidence so far, the following conclusions appear to be justified: 1. Plasmodium vivax malaria contracted by soldiers in foreign countries (South Pacific, Mediterranean and South American areas) which relapses after their return to this country is infective to the native malaria vectors, viz., Anopheles quadrimaculatus Say and Anopheles maculipennis freeborni Aitken. 2. These mosquitoes infected by the imported vivax malaria can transmit the disease by biting a susceptible person. 3. Control measures are as necessary for imported malaria as for native malaria. Military personnel relapsing with imported malaria in an area where malaria vectors are present would offer possibilities for transmission to the population similar to a corresponding number of native malaria cases.

Solution G for Alkaline Incrustations of Urinary Tract.—Heger and Sauer studied the effect of solution G (citric acid, magnesium oxide, sodium carbonate and distilled water) on 41 patients. They selected for treatment patients with persistent alkaline infections of the urinary tract, particularly those in whom a tendency to recurrent or continued formation of incrustations or stones was apparent. A three way Foley-Alcock catheter was placed indwelling, and the solution was administered by means of a drip at a rate of from 40 to

60 drops per minute. Continuous drainage was accomplished by allowing the mixture of urine and solution to escape through the return tube of the catheter. It has been advantageous in suitable cases to elevate the tube draining the return fluid 15 to 30 cm. above the symphysis. Thus tidal drainage and periodic distention of the bladder with a mixture of solution G and urine were accomplished. The patient's fluid intake was held at a level of about 3,000 cc. per day, and the amount of solution G used during twenty-four hours was between 3,000 and 4,000 cc. The results were most impressive in patients with incrustated alkaline cystitis and patients with incrustated radium necrosis. Not only will prolonged employment of solution G prevent recurrent formation of calcareous deposits while it is being administered but also it will exert bactericidal effects by changing the alkaline pH of the bladder content to a pH of 4.6 to 4.0. In the majority of cases, one course of treatment lasting from two to four weeks has been sufficient. As a stone dissolving agent the use of solution G is indicated only under certain conditions. It has proved valuable in cases in which formation of kidney stones occurs as a result of infection with urea splitting bacteria. It is possible to dissolve these stones before they become hard or large. If surgical removal of stones from badly infected kidneys is carried out, nephrostomy should be done routinely in order to facilitate postoperative irrigation treatment with solution G. Also in cases of sandlike deposits or multiple stone formation in the kidney pelvis the authors advocate the use of solution G postoperatively to dissolve the remaining stones and to prevent formation of new stones. The indication for use of solution G for the purpose of dissolving bladder stones is a limited one. Since many of these patients require elimination of some form of obstruction, surgical procedures are preferable. The use of solution G should be advocated for patients with alkaline bladder stones who refuse surgery or transurethral manipulations, for patients for whom such procedures are contraindicated and for patients whose bladders are so badly infected that treatment of the infection is desirable before attempts at removal are made.

Agranulocytosis Caused by Oxophenarsine Hydrochloride and Treated with Sulfadiazine.—Tarnower reports a case which indicates that oxophenarsine hydrochloride (mapharsen) is capable of causing agranulocytosis and severe anemia and as such should be administered with special caution to any one sensitive to an arsenical. Sulfadiazine may be administered in the presence of agranulocytosis. The employment of sulfonamides in the treatment of agranulocytosis with the rationale of combating infection until there is a leukocytic regeneration is worthy of further trial.

Nodular Intrathoracic Lesions in Coccidioidomycosis.—The 3 cases reported by Helper and Watts are significant because of the unusual intrathoracic pathologic changes seen seven to thirteen months after the acute phase of coccidioidomycosis had subsided. These cases have in common chest pain as the presenting symptom, a positive skin test for *Coccidioides immitis*, a negative tuberculin test and an intrathoracic mass. In 2 cases the mass was intrapulmonary, in the third probably intrapleural. While the primary pulmonary infection in each of these cases has been overcome, it has left a residual intrathoracic focus which still shows clinical activity, manifested by chest pain, many months later. This symptom is severe enough to prevent these men from doing military duty. The authors conclude that nodular intrathoracic lesions may be a late residual finding in patients who have recovered from acute pulmonary coccidioidomycosis. They stress that late encapsulated coccidioidomycosis must be included in the radiologic differential diagnosis of circumscribed intrathoracic soft tissue lesions.

Leptospirosis (Weil's Disease) in Minnesota.—Stavitsky and Green say that despite the apparent increase in leptospirosis in man and animals throughout the United States no cases have been reported from Minnesota. The authors therefore inquired as to the presence or absence of the etiologic agent of leptospirosis, *Leptospira icterohemorrhagiae*, in certain groups of the human and animal population in and around Minneapolis and St. Paul. All tests on human material were negative, but in 4 rats evidence of infection with actively virulent leptospiras was obtained by direct dark field observation and animal inoculations of minced rat kidneys. Evidence of past infection of 3 dogs was secured by means of positive agglutination tests of their serums against *Leptospira icterohemorrhagiae* in significant titers of 1:300, 1:200 and 1:100. Although no evidence of human leptospiral infection has been obtained in this area, human cases might well occur. Only 50 per cent of the cases of Weil's disease present jaundice, while some take the form of a relatively benign meningitis with none of the classic symptoms of leptospirosis other than a positive agglutination test. In the latter type of case ordinary bacteriologic studies usually fail to reveal the presence of the organism, as leptospiras do not grow on ordinary bacteriologic mediums and are not stained by the more commonly used stains.

Smoking and Tuberculosis.—A questionnaire was sent to 50 sanatorium directors. The answers revealed that 13 considered smoking definitely harmful to tuberculous patients, 36 considered excessive smoking harmful and only 1 considered it not harmful. Only 16 per cent had rules which rigidly forbade the practice. Most of the men permitted smoking in certain cases or ignored the fact that the rules were being broken. This attitude is engendered by the fact that it is difficult to discourage patients from a habit of long standing in return for a benefit which is of questionable value. An examination of the more recent literature leads to the conclusion that since smoking is harmful even to normal persons it is bound to have a deleterious effect on the respiratory tract of the tuberculous. It is felt that the best approach to the problem would be a definite rule forbidding smoking, with frequent explanations about the dangers inherent in the practice.

- *Observations on Use of DDT for Control of *Anopheles Quadrimaculatus*. R. L. Metcalf, A. D. Hess, G. E. Smith, G. M. Jeffery and G. W. Ludwig.—p. 753.

Use of DDT for the Control of *Anopheles Quadrimaculatus*.—Laboratory and field studies were conducted in the Tennessee Valley during 1943 and 1944 to provide information on the use of DDT as a residual house spray for the control of

the adult *Anopheles quadrimaculatus* and on its effectiveness as an anopheline larvicide and adulticide when applied as a dust, a spray or a thermal aerosol. The results of these investigations are summarized by Metcalf and his associates. Laboratory observations of wall board sprayed at rates of 40,200 and 1,000 mg. of DDT per square foot showed that there was no significant difference in the initial toxicity to adult *A. quadrimaculatus* at the different dosages, the percentage of mortality being determined primarily by the period of contact. Residual toxicity, however, was dependent on the rate of application, though not directly proportional to it; sufficient residual toxicity to produce 100 per cent mortality to adults exposed for sixty minutes persisted for four to sixteen weeks, depending on the dosage. Barns treated with DDT at a rate of about 200 mg. of DDT per square foot remained almost entirely free from flies and mosquitoes for at least eleven weeks. Unoccupied houses treated with DDT at a rate of about 250 mg. of DDT per square foot remained toxic to *A. quadrimaculatus* adults for at least fifteen weeks; occupied dwellings lost their toxicity more rapidly than unoccupied houses but remained toxic to *A. quadrimaculatus* for at least three months. Exposure to DDT surfaces completely reversed the normal light reactions of the mosquitoes, making them positively phototropic. Solutions of 2.5 per cent DDT in kerosene gave effective control of anopheline larvae when applied by boat oiling units at rates of approximately $\frac{1}{10}$ pound of DDT per acre, thereby making possible a reduction of about 98 per cent in the amount of kerosene normally used. DDT had to be diluted with 95 per cent of soapstone before a satisfactory airplane dusting mixture was obtained. With this mixture 90 per cent control of *A. quadrimaculatus* larvae was obtained over 200 foot swaths at actual treatment rates as low as $\frac{1}{10}$ pound per acre. Certain polymethylnaphthalenes (Velsicols) having a high solubility for DDT and a high boiling point were found to be ideal solvents for making liquid solutions of DDT to be applied by airplane. DDT dusts and thermal aerosols gave no evidence of injury to fish or other aquatic organisms when applied by airplane at rates of $\frac{1}{10}$ pound of DDT per acre. Five per cent solutions of DDT in kerosene applied at rates of about $\frac{1}{4}$ pound of DDT per acre were quite destructive to aquatic insects living in close contact with the water surface, particularly Hemiptera and Coleoptera.

Tests of Gallbladder Disease.—Morrison and Swalm present two new tests for the detection of active gallbladder disease. The first is a surface tension method and the second a specific gravity method. The tests are based on the concentrating function of the gallbladder studied in over 5,000 bile specimens. They are often valuable laboratory adjuncts or alternatives to the cholecystogram in deciding for or against gallbladder surgery. For research purposes the surface tension test can be used to determine the concentration of bile salts in the gallbladder bile from the duodenal drainage bile, by the surface tension or stalagmometric method. The normal gallbladder concentrates between 1,000 and 2,000 mg. of bile salts per hundred cubic centimeters of bile in the gallbladder or the B fraction of the nonsurgical biliary drainage bile. Pathologic gallbladders concentrate less than 1,000 mg. of bile salts per hundred cubic centimeters in the gallbladder or B fraction of the nonsurgical biliary drainage bile. When the gallbladder and liver biles are too mixed to make a separate gallbladder estimation, the pathologic gallbladder can often be detected by its inability to raise the concentration of the bile salts in the combined bile to 300 mg. or more above that in the liver bile alone. The estimate from the gallbladder bile alone is the most accurate and hence preferable. In the presence of functional gallbladder stasis or dyskinesia, when the gallbladder

mucosa is still apparently healthy, the bile salts in the gallbladder rise abnormally high to between 2,000 and 3,000 mg. per hundred cubic centimeters of bile. For practical clinical purposes, the specific gravity test consists in determining the density of the B or gallbladder bile in the nonsurgical biliary drainage, and comparing it with the C or liver bile. The specific gravity of normal gallbladder bile is from 0.005 to 0.050 greater than that of the liver bile. The average specific gravity of the normal B or gallbladder bile in a series of 100 cases with proved normal gallbladders was 0.011 greater than the specific gravity of the C or liver bile in the duodenal drainage. The specific gravity of the B bile from the diseased gallbladder is less than the specific gravity of the liver bile, or equals it, or is not more than 0.004 greater than the specific gravity of the liver C bile.

Correlation of Cholinesterase with Bowel Movement and Liver Function.—The substance released by the vagus following electric stimulation is acetylcholine. Cholinesterase was detected as the ferment which splits acetylcholine and which is present in serum and erythrocytes. The quantitative determination of this ferment, particularly by titration, involves many difficulties. Bauer stresses the importance of the pH and of the temperature. He used the method indicated by Butt and his co-workers. Twenty-seven of 208 cases gave high or low readings. Low values have invariably been found in liver diseases, anemia and debility; high values in endocrine disturbances, especially hyperthyroidism. High readings were also obtained in constipation, nephrosis and endocrine disorders, and low readings in anemia, liver diseases, cachexia and septicemia. Control tests with Hanger's cephalin-cholesterol and R. Bauer's magnesium chloride tests showed that positive flocculation results are not always accompanied by low serum esterase values. A large part of the enzymic action is contained in the red cells. Therefore the ratio of the red cells to serum has to be considered especially with liver diseases. The situation seems to be even more complicated since Mendel and Rodney in 1943 split the ferment into pseudocholinesterase and cholinesterase. The current clinical investigations have been made with the unspecific ferment, the so-called pseudocholinesterase. Current clinical investigations do not give a clear insight into the splitting of acetylcholine.

Talcum as an Operating Room Hazard.—Seelig says that if a surgeon dons a pair of gloves that have been powdered with talcum, rinses them thoroughly and then allows them to dry a few minutes, they will still show a coating of talcum. From 50 to 100 mg. of talcum accumulates in the finger tips, and an accidental rip in a finger causes spillage. The process of powdering produces a deposition of powder on materials and instruments that are later used in the operation. Biopsy specimens from omental tissue of patients who are subjected to a second laparotomy frequently disclose talc crystals and foreign body reactions. These reactions manifest themselves as granulomas and as dense adhesions, particularly in the cranial and abdominal cavities. Microscopically the picture resembles that of tuberculosis, and clinically it not infrequently imposes itself as malignant disease. Investigations to find a substitute for the treacherous talcum powder disclosed that potassium bitartrate (cream of tartar) is suitable, and more recently a special starch powder has been developed.

Plasmocytoma of Bone.—Tennent presents evidence that plasmocytoma of bone forms a distinct clinical picture of a solitary intramedullary neoplasm, remaining strictly localized for several years, but if untreated developing into the fatal condition of multiple myelomatosis. A case conforming to this description is reported in which the primary plasmocytoma remained localized in the right ilium for four and one-half years, with subsequent development of multiple myelomatosis and death five years after the first symptoms. This case illustrates the natural history of the disease in the absence of treatment. Analysis of the 50 recorded cases revealed that 35 involved men and 15 women. The distribution was pelvis 16, femur 12, humerus 9, vertebrae 6, skull 5, tibia 1, clavicle 1. Presenting symptoms were either pain, pathologic fracture or local swelling. When the tumor occurred in a long bone the tendency to pathologic fracture was high. There is difference of opinion regarding the origin and nature of these tumors, but the weight of evidence appears to be in favor of the tumor arising as a variant of the reticulum cell. Treatment consisted in amputation, curettage, high voltage x-rays or radium. Nothing is to be learned as to the relative merits of these methods, owing to the lack of adequate follow-up. The prognosis is less favorable than in osteoclastoma and considerably more favorable than in osteogenic sarcoma.

Delayed Paraplegia Following Fractures of Vertebrae.—Rogers says that when paraplegia complicates a vertebral fracture it is usually a concomitant condition produced at once. Rarely, is the onset of paraplegia delayed. He cites cases in which there was an interval between the injury to the back and the onset of paraplegia. A seaman aged 22 was blown up by a torpedo explosion, walked to the ship's side, clambered

overboard, swam away from the ship and then became paraplegic. A member of the air force injured in a Spitfire crash experienced pain between the shoulders but no other symptoms. Paraplegia developed in forty-eight hours. Another patient had a cycling accident. He walked a mile, then sat down because of pain in the back and was unable to rise because of paraplegia. A girl of 17 was in a bicycle collision with a car. She picked herself up, was taken by car to the doctor's house and walked inside. She then developed numbness and paralysis. In 2 of the described cases the paraplegia was transient, resolving completely in a few days' time. In the other 2 cases it was persistent, and exploration was carried out with improvement in both following the removal of bony encroachment on the spinal canal. In the transient cases delayed paraplegia is probably due either to subpial hemorrhage or to edema, which, when fully established at a varying interval after the injury, is sufficient to impair conduction in the cord. With absorption of the effusion in some twenty-four to forty-eight hours or even longer, conduction is once more restored. Persistent delayed paraplegia is an indication for operation and removal of the bone block produced by displacement of the vertebral fragments.

Growth Promoting Substance in Wound Treatment.—Werner says that since a previous report by Kerr and himself on the clinical value of growth promoting substance a further 44 cases have been treated with heart extract powder. All patients had shown indolence and intractability toward orthodox treatment. The use of tissue extract was confined to wounds which had been treated for a period of at least six weeks unsuccessfully. The majority of the lesions responded favorably to the treatment. Three ulcers and one chronic wound can be classified as failures. The same three groups as previously described were treated: (1) ulcers, (2) wounds by projectiles, (3) burns. Further evidence has been collected about the general action of heart extract powder. It has been applied to one of several coexistent wounds with the result that healing in the treated wound was accompanied by healing in the others. Owing to unforeseen circumstances the treatment with heart extract powder had to be discontinued for a fortnight. The treated wounds responded to this interruption in two ways: In the smaller group healing proceeded satisfactorily, whereas in the major group the condition retrogressed. After the treatment was renewed, the patients who had larger lesions responded to the first application of heart extract powder with protein shock. After several applications this reaction subsided. The fact can be explained in the way that the interruption led to an accumulation of antibodies, so that the individual treated responded with a form of anaphylactic shock. The results in chronic burns justify the trial of heart extract powder on fresh burns.

Acute Anterior Poliomyelitis in Malta.—Bernstein and his associates describe clinical and pathologic aspects and treatment of 57 adult patients with anterior poliomyelitis seen among service personnel during the Malta epidemic of 1942-1943. There were eleven deaths. In 2 cases no paralysis was noted. In 26 cases there was no serious final disability. In 14 cases the cranial nerves were involved; in 16 cases there was respiratory paralysis; all deaths resulted from respiratory paralysis despite the use of a mechanical respirator of the Drinker cabinet pattern. Convalescent serum and sulfadiazine were used in a small number of cases without apparent benefit. The onset of the paralysis was often delayed and in a few instances was not apparent until the fifth week.

Erythrocyte Sedimentation Rate in Infective Hepatitis.—Miles followed the erythrocyte sedimentation rate in 80 patients with infective hepatitis throughout their hospital stay. In 40 of the 80 cases the rate was raised above 10 mm. at some stage of the disease, and it was noticed that in these cases the erythrocyte sedimentation rate was low in the acute stage except in a few very mild cases and then became raised as recovery occurred. Estimates revealed that in this series there was a rise in the erythrocyte sedimentation rate as the serum bilirubin fell. There was a strong negative correlation between the height of the erythrocyte sedimentation rate and the serum bilirubin. Evidence has been produced to suggest that an increase in bile salts might cause an inhibition of the erythrocyte sedimentation rate in the acute phase of the disease.

Mumps Meningoencephalitis and Orchitis.—Halcrow and Wang present the case of a soldier aged 26 in whom an almost latent parotitis was followed three days later by a fairly severe orchitis, thirty-six hours after which meningoencephalitis manifested itself. Recovery was complete and rapid. Although the patient had been given sulfadiazine, the authors do not think that it influenced the course of the disease.

Localized Leishmaniasis of Lymph Glands. H. L. Chung, with a note by V. T. Lieu.—p. 284.

Treatment of Lobar Pneumonia in Children.—According to Su and Lee, lobar pneumonia is common among Shanghai children. The 105 cases reviewed occurred among 2,745 hospital admissions between February 1938 and March 1941, giving an incidence of 3.83 per cent. There was a seasonal increase in December, and the highest peak was reached in February and March. Forty of the children were less than 2 years old. Seventy per cent of the patients were boys. Thirteen of the 105 patients died, 6 of them within twenty-four hours of hospitalization. Studies were made on 56 patients who were treated with sulfonamide derivatives and 39 who received no chemotherapy. Sulfapyridine was used in 40 cases and was found to shorten the fever period, but the incidence of toxic reaction was fairly high. Sulfathiazole showed a good result in 5 cases so treated, and the incidence of its toxic reactions was less frequent.

*Glass Fiber: Pathology and Hygiene of Workshops. J. Champeix.—p. 91.

Hygiene of Workshops Handling Glass Fiber.—Champeix says that to the long list of insulating materials there has been added in France during the last ten years a heat resisting substance of a glass fiber base. Whereas formerly heat insulators were mostly of an asbestos base, glass fiber is used now more and more. Manifestations of mechanical irritation were observed. They consisted of cutaneous erythema with pruritus, blepharitis and rhinopharyngeal irritation. Neither clinical nor roentgenologic observation disclosed pulmonary changes, but the glass fiber had been used by these workers for only six months and, even if danger of silicosis existed, several years would have to elapse for pulmonary changes to be roentgenologically perceptible. The weaving of glass fiber is not so much harmful as annoying to the workers, because of the almost incessant pruritus caused by the glass dust. He recommends a number of protective measures, such as catching the glass dust at the level of the loom so as to avoid its dissemination, good ventilation of the work shop, individual dressing rooms so that every worker can completely change his clothing before and after work because the dust of glass fiber passes through ordinary clothing and the wearing of tightly woven work clothing so as to avoid as much as possible the penetration of the glass fiber. Shower baths should be provided for the workers at the end of their working time so that they can clean their body from the glass fibers that have penetrated the clothing. The parts of the body not protected by clothing should be coated with soothing ointments, before and after work, to attenuate if not prevent the pruritus. Eating in the workshop should be prohibited. When workmen are engaged for working with glass fiber they should be subjected to a medical examination so as to avoid those with cutaneous and pulmonary lesions. Those working with glass fiber should be periodically examined.

Two Cases of Bronchoclerosis (So-Called Valvular Stenosis). A. Gunther.—p. 2146.

Liver Extract in Pernicious Anemia.—Waldenström says that treatment with injections of liver extract can be carried out on a large scale with excellent results at a minimum cost. Of his present 160 patients with pernicious anemia 103 have been treated for at least four years with an average number of 5.3 injections annually for men and 5.1 for women with an annual cost varying from 18 to 42 Swedish kronor. The average number of erythrocytes maintained was 4.1 million for men, 4 million for women. Five patients were given liver preparations orally because of severe reactions to several brands of liver extract. Reactions which occurred in 17 of the 160 cases were usually overcome by injection of a different preparation.

Book Notices

Clinical Traumatic Surgery. By John J. Moorhead, B.S., M.D., D.Sc. Cloth. Price, \$10. Pp. 747, with 500 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

In his book the author has summed up his vast experience in the field of occupational accidents as the medical director of the New York Transit System. His participation in World War I and the professional care of the victims of the memorable Pearl Harbor attack entitle him also to speak authoritatively on war injuries. Long teaching experience helped him to avoid confusing lengthy discussions and to recommend therapeutic measures characterized by safety and simplicity. The subject is discussed in a simple, concise and lucid manner.

Special chapters cover regional traumatology, such as treatment of the wounds of the hand and injuries of the head, chest and abdomen. As could be expected, considerable space is given to the treatment of fractures. Special sections cover the medico-legal aspect of traumatic surgery, compensation problems and allied subjects. Traumatic neuroses are discussed in a separate chapter. The text is profusely illustrated with adequate drawings and reproductions.

As the author states in the preface, the average reader seeks the opinion of the writer and therefore bibliographic references have been omitted.

One may not share the author's choice of "I. S. Solution," made up of tincture of iodine and sterile saline solution for the treatment of infected wounds. "Intraclavicular dislocations of shoulder" (p. 309, fig. 143) is bad terminology because the prefix "intra" means "within" and not "median to"; obviously the dislocated head of the humerus cannot be found within the clavicle. The author speaks of Dupuytren's contractions; the term "contracture" is commonly used because it implies that the condition is permanent, while "contraction" indicates a condition of short duration. The heading "Fractions of the Spine" (p. 392) is evidently a typographic error. On page 474, eighth line from the top, the author recommends flexion and adduction of the wrist in order to reduce Colles' fracture. However, ulnar deviation is called abduction and not adduction.

Such minor errors do not detract from the value of the book, which represents a veritable mine of information valuable to a specialist as well as to a general practitioner dealing with injury cases. It is amazing that such an enormous amount of material could be covered in one volume.

Fundamentals of Pharmacology. By Clinton H. Thienes, M.D., Ph.D., Professor and Head of the Department of Pharmacology, School of Medicine, University of Southern California, Los Angeles, Calif. Medical Students Series. Cloth. Price, \$5.75. Pp. 497, with 36 illustrations. New York & London: Paul B. Hoeber, Inc., 1945.

To write a concise and comprehensive textbook on the fundamentals of pharmacology which will meet the needs of both students and practitioners and at the same time stimulate the interest of investigators is not an easy task. Dr. Thienes has written a book to meet these requirements. The book is divided into twelve sections, beginning with the systematically acting drugs the effects of which are better understood. Central nervous stimulants and depressants, drugs acting on the peripheral nervous system, drugs acting on the muscles and diuretics occupy the first half of the book. This is followed by anti-parasitic drugs, hormones, minerals, tissue extracts and vitamins. Expectorants, emetics and cathartics are included in the section on drugs used because of local action on body surfaces. Chemical diagnostic agents and actions of drugs on cells are treated in two separate sections. Pharmacy and prescription writing form the last section of the book. The chapters on anesthetics and actions of drugs on cells are well written. The discussion on cellular structure and metabolism in the light of recent knowledge of enzyme systems and the discussion on quantitative pharmacology in relationships between drugs and cells and in terms of biologic variation are not usually given in general textbooks on pharmacology. In chapters on sympa-

thomimetic and parasympathomimetic drugs there is no mention of the classification of these autonomic drugs based on adrenergic and cholinergic innervations as advocated by recent investigators. Each drug is presented uniformly throughout the text in the following sequence: sources, chemical nature, preparations, dose, absorption, distribution, fate, excretion, pharmacodynamic effects, toxicology and therapeutic uses. A few important references are given at the end of each chapter.

The book is clearly written and up to date. Some of the recent medicinal agents included in the text are propadrine and other synthetic sympathomimetic drugs, dicumarol and penicillin. The revival of interest in curare and veratrine as therapeutic agents is mentioned. Some of the features that will appeal to medical students are the brief introduction at the beginning of each section, the uniform procedure in the exposition of each drug and the differential analyses of drug actions. The author's emphasis on rational therapy and his discussion of empirical medicine are of special value to practitioners. His critical discussion of controversial topics is another good feature. The text serves well to introduce students to the essentials of pharmacology and to lead them to more comprehensive treatises for details. Practitioners and others will be benefited from it for a quick review of the subject and for a glimpse of the recent advances in the field of pharmacology.

Temas de cirugía de urgencia. Tomo I. Por P. Larghero Ybarz, profesor de patología quirúrgica, cirujano de urgencia de los Hospitales Maciel y Pasteur. Laboratorio de la Cátedra de patología quirúrgica (primer curso), Facultad de medicina de la Universidad de la R. O. del Uruguay. Paper. Pp. 324, with illustrations. Montevideo: Libreros Editores: A Monteverde y Cia "Palacio del Libro," 1944.

The author, in writing this book on first aid, has used to good purpose the experience obtained as surgeon, for a number of years in two Montevideo hospitals. It is not, however, a general handbook on the subject but an excellent and occasionally overlong review of some of the most difficult problems he has faced, with representative case reports, tables of results and some fine illustrations. The subjects discussed are gastro-duodenal hemorrhages, abdominal wounds, water balance in serious cranial trauma, bronchopulmonary complications in emergency operations, diagnosis of acute appendicitis, peritonitis in typhoid and suppurative mesenteric adenitis. The pathologic picture is invariably emphasized but also related to the clinical and other data.

An Introduction to Medical Science. By William Boyd, M.D., M.R.C.P., F.R.C.P., Professor of Pathology and Bacteriology in the University of Toronto, Toronto, Canada. Third edition. Cloth. Price, \$3.50. Pp. 366, with 126 illustrations. Philadelphia: Lea & Febiger, 1945.

This book is designed for nurses at the beginning of their professional careers. It aims to be a general introduction to the study of disease. The first portion of the book deals with general principles, including a chapter on the living body and one on the nature and cause of disease. The second portion deals with the organs and their diseases, namely diseases of the heart, diseases of the lungs, diseases of the urinary system and the like. The final chapter is on practical applications—the prevention of disease, the principles of the treatment, the nurses of the laboratory. The author is a well known pathologist, and the book should be extremely useful for the purpose for which it is intended.

Los grandes síntomas y síndromes: Síntesis de terapéutica clínica. Por Ambrosio Nijensohn. Paper. Pp. 366. Buenos Aires: "El Ateneo," 1944.

An effort has been made throughout this monograph to live up to its subtitle of synthesis of clinical therapeutics and furnish in a condensed form the accepted treatment for the different conditions described. After a short sketch of the situation, the proper care is prescribed. The real novelty is that the measures advised are based on the most striking symptom or syndrome facing the physician when he first sees the patient. This by itself limits the field embraced. The different conditions are grouped, as gastrointestinal, respiratory, spleen, glands, nerves, skin and general. All are discussed sensibly and clearly, based on common sense, experience and knowledge.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TREATMENT OF HERNIATED INTERVERTEBRAL DISK

To the Editor:—Is there a definite indication for operation in herniated intervertebral disk or does conservative treatment really cure the condition? The concert of present day opinion on the subject shows the most dissimilar chords. There are those to whom any sore back with sciatica is a herniated intervertebral disk, and there are those who take pains in reaching such a diagnosis. In the latter group belong Philip Lewin (Backache and Sciatic Neuritis, Philadelphia, Lea & Febiger, 1943), Bernard I. Comroe (Arthritis and Allied Conditions, ed. 3, Philadelphia, Lea & Febiger, 1945), J. Jay Keegan (The Journal, Dec. 2, 1944, p. 868) and John J. Moorhead (S. Clin. North America 24: 467 [April] 1944). These authors agree that several diagnostic procedures and signs will indicate a herniated intervertebral disk, but not one of them is sufficiently sure in his diagnosis to permit operation. They recommend months of conservative treatment: strapping, plaster, heat, massage and traction. If the patient is not improved after months of conservative treatment, an operation is recommended. It does not seem very scientific and efficient to exhaust a patient's material means, time and patience with procedures of uncertain effect and then, if necessary, operate on him. It should be possible to determine the 10 per cent who are not going to be improved by conservative treatment at the first examination. It does not seem very logical that a once ruptured intervertebral disk should be completely cured by conservative measures. No observations have been published on the later fate of conservatively treated ruptured disks. I wonder if the patient's life will not be marked by terror and a steady caution in fear of recurrence, and thereby invalidity. The reason given for such over-conservatism is that the results of some surgeons are not always good. If we point to the older series of Love and Walsh with its splendid results, then we may come to the conclusion that perhaps some operative minded neurosurgeons do not differentiate strictly enough between a herniated disk and Steindler's posterior division syndrome, and between a disk, a local fibrositis and plain hysteria. If the diagnostic zeal of the conservative group could be followed by prompt operation, and if the operative zeal of the surgical minded group could be supplemented by more careful selection of cases and accurate differential diagnosis, the patient might be better served.

George Vash, M.D., Philippi, W. Va.

ANSWER.—Whether one should promptly resort to surgery in treating a patient diagnosed as having a protruded intervertebral disk or whether the treatment should be conservative with rest, traction and heat is a question with many angles. The clearest cases of protruded intervertebral disk which warrant surgery are fairly typical. The patient is usually a man from 20 to 40 years of age, with a history of sudden onset of backache, usually incident to a strain or fall. There is commonly associated sciatic pain radiating down one leg accompanied by a tilt of the body usually away from the affected side and a prominence of the iliac crest on the affected side—a condition spoken of as sciatic scoliosis. If, in addition, there are neurologic findings such as a diminished or absent achilles tendon jerk and anesthesia over a nerve root distribution, the diagnosis is pretty certain. If, with the symptoms mentioned, there is also a positive spinogram, there is no reason why surgery should not be undertaken even though there has been no previous attack. Although some surgeons say that a spinogram is not necessary, it is better that one be made in each case because spinal cord tumors can and do exist, and the use of such a valuable aid as a spinogram should not be neglected to assist in the differential diagnosis. Such conditions in the past were thought to be due to sacroiliac arthritis and were treated as such. Patients often had recurrences over many years, and too often atrophy of the leg and even some paralysis were residual. Many patients who have protruded intervertebral disks involve compensation; that often casts a shadow over recovery. In this type of surgery it is much to be desired that the patient understand the situation and accept the operation without any pressure from the surgeon.

SLIPPING AND LOCKING OF JOINTS

To the Editor:—A woman aged 51 has joints that tend to slip and lock. She has several in the spine, in the fingers and in the knees. When the joints lock there is extreme pain. The patient had a fibroid tumor, which was successfully removed. All bodily functions are normal and she is perfectly healthy otherwise.

M.D., Illinois.

ANSWER.—Without a more detailed history and record of more complete physical findings, it is possible only to hazard a few opinions with regard to diagnosis or treatment. A history of slipping and locking in the fingers suggests tendonitis.

The classic snapping finger is usually misunderstood by those who have not seen a number of these and is thought to be due to subluxation with locking in the joints. Tendonitis, which produces this condition, may involve only one or a number of digits. Subluxation of multiple joints would be extremely rare. A sensation of slipping followed by locking in the knee is most often the result of partial to complete dislocation of the patella. Somewhat similar symptoms may be produced by internal derangement of the knee due to the presence of osteocartilaginous loose bodies, hypermobile semilunar cartilages or actually torn and displaced semilunar cartilages. Recurrent subluxation or dislocations within the spine occur only in the posterior articular facets. The weight bearing vertebral bodies can be displaced one from the other only as a result of extreme violence or following separation of the isthmus, creating a spondylolisthesis. When such dislocations do occur they can rarely be replaced. Abnormal ranges of motion between the joint surfaces of the posterior articular facets due to over-relaxed joint capsules or ligaments may permit impingement on a posterior nerve root. When this root is traumatized, the patient experiences pain along the distribution of the nerve fibers. A reactive muscle spasm of the sacrospinalis muscle group may be painful and produce scoliosis, which persists until the muscle spasm can be relieved. Intervertebral disks have been shown to bulge, intermittently after a partial tear of the posterior portion of the annulus fibrosus. Each such protrusion of the disk may pinch a posterior nerve root against the bone of one of the appendages of the spine, causing pain, muscle spasm and scoliosis. A complete study of this patient from the standpoint of history and physical findings carried out by an orthopedic specialist will probably be required if an accurate diagnosis is to be made or effective treatment is to be prescribed.

MUSCLE ATROPHY AND SCAR FORMATION FOLLOWING COMPOUND FRACTURE

To the Editor:—A patient has a healed compound fracture of the upper third of the femur. He can straighten the leg on the thigh but can flex it not more than 15 degrees. The quadriceps is greatly shrunken. The probable diagnosis is that the muscles are caught in the healed bone lesion with scar formation near the fractured area. I am considering cutting down on this, and if a cicatrix is found I expect to excise it. What is usually found in such cases and what should be done? If the diagnosis is correct and the scar is excised, will a fascial transplant be required to prevent the occurrence of fixation?

Coleman G. Buford, M.D., Elizabeth, Ill.

ANSWER.—It seems remarkable that the patient can fully extend the leg on the thigh with an atrophic quadriceps and a possible scar inclusion. Presumably some of the fibers of the quadriceps have escaped damage or adherence. It may be possible in an ischemic field to excise the scar and adherence and close up the muscle fibers. This would not be a guaranty against a readherence to the bone or periosteum and it would be wise to make a fascial transplant of sufficient area, with adherent fat surface to be turned up beneath the repaired muscle, with the fascial surface against the bone. Early active use of the muscle should then be encouraged after wound healing. A most careful hemostasis is required in this procedure to prevent formation of a hematoma.

SANITATION OF HOSPITAL FLOORS—PREVENTION OF FUNGUS INFECTIONS

To the Editor:—I should like to know the modern and efficient method in vogue in hospitals for the sanitary care of ward floors, toilets and bathrooms. Is it necessary to mop the floors and wash the toilets in wards where patients are incontinent, urinate and defecate on the floors with such drugs as cresol solution or is soap and water all that is necessary? What is the proper prevention of fungous infections of the feet? Will mopping the floors of the wards and bathrooms with such antiseptics as cresol be a preventive or should a 1 per cent solution of sodium hypochlorite be used before and after bathing?

M.D., Tennessee.

ANSWER.—As a general policy the use of cresol solutions on bathroom and latrine floors which become soiled by urine and feces is not recommended. Adequate scrubbing with soap and water and thorough flushing with clean water, under pressure when necessary, is sufficient. If desired, the floor may be "freshened" by flooding with a chlorine solution after cleaning with soap and water. For this purpose 1 ounce of calcium hypochlorite (70 per cent available chlorine) or 2 ounces of chlorinated lime (35 per cent available chlorine) in 5 gallons of water allowed to stand ten to fifteen minutes before flushing off with fresh water is adequate.

With regard to the prevention of fungous infections of the feet, the following extract from the *Bulletin of the U. S. Army*

Medical Department, November 1944, is quoted: "Recent studies on the use of hypochlorite solutions for the prophylaxis of 'athlete's foot' have thrown doubt on the effectiveness of this method of control. The consensus is that hypochlorite foot bath solutions are not effective in the prevention of spread of dermatophytosis. Their failure to prevent spread of fungous infections has been attributed to various factors inherent in chlorine solutions. Of chief importance among these factors are the variable rate of decrease in concentration and limitation of range of effective fungicidal concentrations. The former factor is more or less common to all foot bath solutions; the latter is peculiar to chlorine solutions. Limitation of range of effective fungicidal concentration is due to the following features: 1. Hypochlorous acid, the active fungicide, is not formed in effective amounts above pH 8. 2. Strong solutions of calcium or sodium hypochlorite yielding 1,000 parts per million of free chlorine have a pH above 8 and are too alkaline to form effective amounts of the active fungicide. While the use of this concentration would be practicable as regards maintenance, it would be ineffective as a fungicide. 3. Although dilution of hypochlorite solution produces greater dissociation, a lower pH and more of the active fungicide, an effectively low concentration yielding 100 parts per million of free chlorine would require replenishment hourly when used by as few as fifteen men. The use of this concentration is therefore impracticable. It seems probable that any foot bath solution would be ineffective for the following reasons: 1. Even if foot baths killed all the free spores, a certain proportion of spores are encased in the keratin of epidermal scales. 2. Any solution which would dissolve keratin rapidly enough to be effective in killing keratin-encased spores in a foot bath would also dissolve the horny layer of the sole and produce a severe dermatitis. 3. The spores which are keratin encased are tracked on to floors adjacent to foot baths, subsequently become freed from the scales, sporulate and then serve as the main source of reinfection. It is therefore suggested that emphasis be placed on the following mechanical methods of prophylaxis: 1. Flushing of shower room and barracks floors with water under pressure. 2. Scrubbing of floors with brush and detergents. 3. Exposure of flooring or duckboards, when practicable, to direct unfiltered sunlight after application of the methods described in 1 and 2. It is believed that more progress will be made in the reduction of athlete's foot by these means than by the use of foot baths."

ARMY USE OF SALTPETER

To the Editor:—It has been repeatedly called to my attention that the Army puts certain chemicals in the food, probably some potassium salt, which greatly reduces sexual desire and the number of erections. I have been unable to learn anything definite about this. However, since being a patient here and eating away from home for a few weeks, I find that is definitely the condition in myself. Perhaps this is all psychic, but it has never occurred to me before and there is no physical reason for it now. Is this assumption correct, and if so what preparation is used? Is there such a drug that can be used without permanent harm to the individual?

Lieutenant (MC), U.S.N.R.

ANSWER:—Saltpeter is used and has been used for years in curing most meats for both civilian and military use. The amounts used and the reasons for its use by the Army are identical with the use to which it is put in food for civilian consumption. Medicinally the uses of this chemical are identical with those of the best of civilian medical practice. Saltpeter is not used by the Army for its popularly reputed anaphrodisiac action—a reputation not justified by the facts in nontoxic doses.

MALARIA

To the Editor:—Can the parasites of malaria be detected in a blood smear when the patient is taking atabrine? I have in mind an army officer who has just returned from eighteen months in the Philippine Islands and who has been taking the usual daily army preventive doses. Can malaria be diagnosed and treated without allowing the patient to stop atabrine?

Robert R. Snook, M.D., Manhattan, Kan.

ANSWER:—In order to determine whether cure has taken place, it is always necessary to remove the drug. If a patient is taking atabrine constantly it is practically impossible to demonstrate any parasite in the blood smear. In order to establish positive diagnosis, it is necessary to take from the patient all antimalarial drugs. It is probably preferable to remove all suppressive medication and treat the attacks as they occur. This point, however, is not established.

EMBALMING OF BODIES

To the Editor:—What are the usual components of the common embalming fluids and in what proportion are they used? What quantity of the embalming fluid is used? Is it necessary to use two or more kinds of embalming fluid? Are there any good books on embalming? Those by Charles A. Renaud and C. F. Callaway do not mention the composition of the embalming fluids. Who performs the embalming work in the United States? Is it well considered and ethical in the United States for physicians to do this type of work?

M.D., Cuba.

ANSWER:—The composition of modern embalming fluids varies greatly. Most of these fluids are dispensed in a concentrated form and the manufacturer furnishes directions for dilution. The formulas are trade secrets. The main purpose of an embalming fluid is to preserve and disinfect the tissues; hence the diluted fluid injected into the body must have sufficient strength to be a disinfectant. The basis of most embalming fluids is solution of formaldehyde, ethyl alcohol, glycerin and certain inorganic salts. Approximately a 5 per cent concentration of the first three ingredients makes a suitable fluid, although many other factors must be considered: Solution of formaldehyde disinfects and preserves. It hardens the tissues and contracts the capillaries but lacks penetrating power; hence it alone is not a good fluid for embalming. To overcome the hardening action of formaldehyde, glycerin is added; this renders the tissues soft and pliable and allows the capillaries to expand on injection. The penetrating power is increased by the addition of ethyl alcohol, which enables the formaldehyde solution to penetrate much farther into the tissues than if injected alone. These three substances, formaldehyde, alcohol and glycerin, are sufficient for preserving and disinfecting. However, their combination and use have many difficulties; for this reason most manufacturers have added other materials to aid the disinfection and preservation of the general appearance of the body. In recent years certain organic compounds known as glycols have been employed as substitutes for glycerin and alcohol. These compounds are good penetrating agents and many of them have antiseptic properties.

For proper drainage and good embalming, a fluid must contain certain inorganic salts to give the final diluted embalming fluid an osmotic pressure corresponding to that of the blood. Such a solution will prevent hemolysis of the red blood corpuscles, thus preventing further staining of the tissue. It will also assist in the removal of blood pigments and other blood residues. For this reason inorganic salts, especially sodium chloride, are added to embalming fluids. Many chemical materials may be used in embalming fluids in addition to the ones mentioned. Saltpeter, benzoic acid, sodium benzoate, salicylic acid, sodium salicylate, borax and many other compounds are used.

The quantity of the embalming fluid varies and depends on the blood removed for the natural lifelike appearance of the individual. The cause of death, duration of the illness, pathologic conditions, medicines administered, condition of the tissues as to moisture content, climatic conditions and the interval between death and embalming play an important part as to the quantity of fluid used. An average of 2 to 3 gallons of diluted embalming fluid is used for the average case.

In modern embalming two types of embalming fluids are used, one for the arterial work as described and one for the treatment of the visceral organs. The cavity fluid differs from the arterial fluid in that it contains a greater concentration of formaldehyde. In the average body 16 ounces of the cavity fluid is used as a direct injection by means of a trocar into the visceral organs. Hollow visceral organs are aspirated before cavity fluid is injected. The arterial fluid may be used for the injection of the visceral organs, but this is not recommended.

Apparently embalming textbooks do not give the composition of embalming fluids. The following textbooks may be obtained relative to this subject:

Outline of Chemistry, R. P. MacFate, Ph.D., Worsham College of Mortuary Science.
Principles of Embalming, R. G. Reichle, B.S., Worsham College of Mortuary Science.
Chemistry of Embalming Fluids, Simon Mendelssohn, Cincinnati.

In the United States embalming is done by licensed embalmers. Each state requires, by statute, certain qualifications before an applicant is eligible to receive an embalmer's license. In the United States if a physician wished to practice embalming and funeral directing it is necessary to fulfil such requirements before being permitted by law to do so. The law, however, does not apply to the preparation of anatomic material for use in medical colleges.

ORAL PENICILLIN

MAXWELL FINLAND, M.D.

MANSON MEADS, M.D.

AND

EDWIN M. ORY, M.D.

WITH THE TECHNICAL ASSISTANCE OF CLARE WILCOX
BOSTON

The early studies on the absorption of penicillin indicated that most of an orally administered dose is probably destroyed by the acidity of the normal stomach. Nevertheless, the small amounts recovered from the urine and the demonstration of activity in the serum suggested that some absorption does take place.¹ When, more recently, doses of 100,000 units were given on an empty stomach, the amounts excreted in the urine were the same as or larger than the quantities usually given in a single intramuscular injection,² suggesting that the oral method is feasible if larger doses are used. A number of antacids, buffers, capsules and oils have been used in attempts to protect the penicillin from the acidity of the stomach. These, as well as substances intended to increase absorption, have given conflicting results.³ Almost all workers found wide variations in absorption by different persons. Although some have suggested that the use of one or another of the adjuvants with oral penicillin resulted in absorption of amounts approximating those obtained from similar doses given intramuscularly, most of them found that from two and one-half to five times as much penicillin is required when given by mouth. In persons with achlorhydria there is more complete absorption from the stomach.⁴ Some of the recent studies have also indicated that, when a dose is given after a meal, lower serum levels are obtained and less penicillin is recovered from the urine

than when the same dose is given before a meal.⁵ Preliminary clinical trials in small numbers of cases of pneumonia⁶ and in gonococcal and other miscellaneous infections⁷ have suggested that oral therapy may be feasible.

In this paper are presented the results of a study of the effective absorption of penicillin after oral administration as indicated by the levels in the serum. Several preparations were compared in single doses in the same individuals, both normal persons and persons with achlorhydria. The results of a preliminary clinical trial in patients with acute gonorrhea and with pneumococcal pneumonia will also be summarized.

MATERIALS AND METHODS

The subjects used as controls in this study were members of the laboratory staff. One of them (subject D) had a history of peptic ulcer and had gastric hyperacidity and hypermotility. The achlorhydric subjects were patients with pernicious anemia who were in various stages of remission induced by active anti-anemia substances. The penicillin was taken either one-half hour before or after breakfast was started. Blood was drawn at one-half, one, two, three and four hours after a dose or at other intervals when indicated. Serum levels were done by the serial dilution method of Rammelkamp⁸ using the same strain of hemolytic streptococcus, No. 98, but with human group O cells as an indicator to avoid heterogenous hemolysis. The smallest amount of penicillin detected when 0.5 cc. of serum was added to 0.5 cc. of the culture was 0.0156 unit per cubic centimeter (recorded for brevity as 0.02 unit per cubic centimeter). When 0.2 cc. of serum was used, the smallest amount detected was approximately 0.03 unit per cubic centimeter.

The oral preparations were supplied by Lederle Laboratories, Inc., Hoffman-LaRoche, Inc., and Commercial Solvents Corporation. A small supply of commercial penicillin sodium for use with aluminum hydroxide gel (Creamalin) was supplied by the Winthrop Chemical Company. Capsule A contained 15,000 units of crude calcium penicillin mixed with shellac, beeswax and cottonseed oil. Powder A was the crude penicillin powder used to make capsule A. Capsule B contained 25,000 units of calcium penicillin in corn oil. Tablet C contained 30,000 units of calcium penicillin with a highly soluble binder. Capsule D con-

tained 25,000 units of sodium penicillin. The two latter preparations each contained a buffer and other solids, the nature of which the makers prefer to keep as a trade secret. Aluminum hydroxide gel was used by mixing three parts with two parts of the saline solution of penicillin, the latter containing 5,000 units per cubic centimeter.

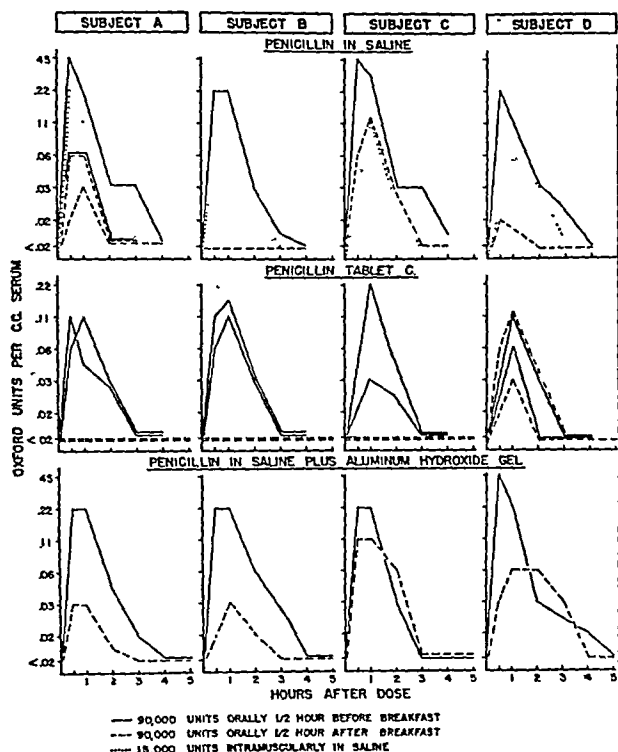

Chart 1—Serum levels after single 90,000 unit doses of penicillin given orally before and after breakfast in 4 normal subjects. Comparison with 15,000 units given intramuscularly.

The pneumonia patients treated were routine admissions to the medical wards. The patients were selected because they were acutely ill, had the typical clinical picture of lobar pneumonia and had previously received neither penicillin nor sulfonamide drugs, and typable pneumococci were found in characteristic sputum. The cases of acute gonorrhea were ambulatory and were treated in the outpatient clinic. They all had the typical clinical picture, and positive smears and cultures were obtained from the exudate before treatment. Most of the strains of gonococci were sulfonamide resistant. Whenever possible, the smears and cultures were repeated after the course of treatment was completed, that is, before the patient left the clinic, and again on the following day and at weekly intervals for three weeks before they were discharged as cured. Unfortunately, some of the patients did not have the complete follow-up. Prostatic secretions were obtained by massage from the male patients in whom there was no further urethral exudate.⁹ Patients who had positive smears on the day after treatment or within three weeks were considered as failures and were retreated with intramuscular preparations. Those with incomplete follow-up who had negative cultures and were clinically well for one week were considered as probable cures, since they cannot be considered as definitely cured.¹⁰ Patients who had

apparent clinical and bacteriologic cures for at least one week and later returned with symptoms and discharge beginning more than four days after an exposure to a known source of infection were classified as reinfections. Bloods were taken for levels at irregular intervals during the course of treatment in most of the patients.

SERUM LEVELS AFTER SINGLE DOSES

Normal Subjects.—The results obtained in 4 subjects with single oral doses of 90,000 units of three different preparations of penicillin given both before and after breakfast are shown in chart 1. The levels obtained after a single intramuscular injection of 15,000 units of sodium penicillin in saline solution are also shown for comparison. All of the observations with tablet C and those with penicillin in saline solution given orally to subject A were done twice. From this chart it is seen that:

1. The doses given orally before breakfast all produced serum levels which were usually better than those obtained from 15,000 units intramuscularly. Many of the levels compared with those obtained after an intramuscular dose of 25,000 units.¹¹ These serum levels, moreover, were fairly comparable in different subjects, the variations being no greater than those found after intramuscular doses in different subjects or after repeated doses in the same subject.¹¹
2. Ordinary commercial penicillin given orally in saline solution one-half hour before breakfast produced serum levels which were as high as and were maintained as well as or better than similar amounts given under similar conditions but in a specially prepared tablet which allegedly contained "buffers" and "stabilizing agents," or when the saline solution of penicillin was given together with aluminum hydroxide gel.
3. The same doses given to the same subjects one-half hour after a similar meal resulted in levels which varied considerably from the different preparations and in the different subjects. (a) Penicillin could be detected in the serum in only 1 of the 4 subjects after tablet C, and

Chart 2—Left, serum levels obtained when the same dose was given orally after breakfast in a powder and in a capsule containing adjuvants. Right, serum levels after single 300,000 unit doses before and after breakfast in 2 normal subjects.

the same results were obtained on two separate occasions in each subject. (b) The greatest variations were noted with the saline solution given after a meal: Subject B had no demonstrable penicillin in the serum, subjects A and D had low levels on one or two occasions and

9 Mrs. Helen Trousdale made the bacteriologic determinations and rendered other valuable assistance in this part of the study. The patients were treated through the courtesy of Dr. Herbert H. Howard.
10 Lapenta, R. G.; Weckstein, A. M., and Sarnoff, H.: The Inadequacy of a Standardized Dosage of Penicillin in the Treatment of Gonococcal Urethritis, *J. A. M. A.* 128:168 (May 19) 1945.

11 Ory, E. M.; Meads, M.; Brown, B.; Wilcox, C., and Finland, M.: Penicillin Levels in Serum and in Some Body Fluids During Systemic and Local Therapy, *J. Lab. & Clin. Med.*, to be published.

subject C had levels comparable with those obtained after the 15,000 unit intramuscular dose. (c) The saline solution of penicillin mixed with aluminum hydroxide gel and given after a meal gave rise to low serum levels for one or two hours in subjects A and B and moderate levels which were more sustained in subjects C and D.

Chart 3.—Serum levels after single 90,000 unit doses of penicillin given orally before and after breakfast in 4 patients with pernicious anemia.

4. The variations observed with the doses that were taken after a meal were not consistent in the different individuals. Thus subject D, who was the only one having good levels from tablet C, showed the poorest serum levels after the saline solution and the most sustained level when the same solution was given mixed with the aluminum hydroxide gel. (This subject is known to have gastric hyperacidity and hypermotility.) Subjects A and C obtained comparable serum levels after the penicillin in saline solution with or without the added gel while failing to get demonstrable levels from tablet C.

The serum levels obtained in 2 of the same subjects when 300,000 units was taken in the form of capsule A before and after breakfast are shown in the right side of chart 2. Absorption was more rapid and more complete when the dose was given before the meal. The maximum levels were higher each time in subject D. The levels in every instance were maintained longer than was the case with the 90,000 unit doses, and they were better sustained in subject D than in subject A.

On the left hand side of chart 2 are shown the levels obtained in 2 of the normal subjects with the same dose of penicillin given after a meal, once in the form of crude penicillin powder and again in capsule A, in which this same powder, mixed with shellac, beeswax and oil, was enclosed in a thin gelatin capsule. The maximum levels in the same subject were similar but were attained later with the capsule than with the powder. In subject B the levels were also sustained longer when the penicillin was taken in the capsule containing the adjuvants.

Achlorhydric Subjects.—The serum levels after 90,000 units given orally before and after a meal in 4 patients with pernicious anemia in remission are shown in chart 3. The penicillin was demonstrable in the achlorhydric subjects for four to six hours, as compared with only two to four hours in the normal subjects. Here again the levels were higher and somewhat better sustained when the dose was given before a meal, and they were quite irregular when it was given after a meal. Furthermore, the maximum levels were generally higher in these subjects than in the normal ones when the same materials were given under the same conditions. The penicillin appeared in the serum later when the dose was given after breakfast than it did in the same subject when the same dose was given before a meal. The highest levels were obtained when the dose was given in saline solution either before or after a meal.

SERUM LEVELS DURING REPEATED ORAL ADMINISTRATION

Normal Subjects.—Prior to embarking on a therapeutic trial with oral preparations it seemed desirable to determine whether serum levels could be maintained with large doses given orally at frequent intervals. A large priming dose was given in the morning immediately before breakfast, and the sustaining dose was given one hour later and repeated at two hour intervals for four more doses. Dinner was taken just before the fourth dose. This sort of schedule seemed applicable in the outpatient clinic for use in the treatment of acute gonorrhea. The serum levels in 4 control subjects given two different amounts of penicillin in capsule A on this time schedule are shown in chart 4.

There were considerable variations in the results obtained in the 4 subjects. In subjects D and E the penicillin was detectable and reached significant levels after an hour. In subject B none was detected until the third hour, and in subject A it was first demonstrated only after five hours. In all 4, however, there

Chart 4.—Serum penicillin levels during repeated oral doses in normal subjects.

were significant, though variable, amounts in the serum for at least six of the ten hours during which observations were made. The levels did not show any constant fluctuations in relation to the meals. It seemed from these preliminary observations that the larger initial dose and the larger follow-up doses were more desirable.

Patients Under Therapy.—The serum levels obtained at different times during the course of the oral administration of some of the preparations in the treatment

of patients in the clinic and in the wards, using somewhat similar dosage schedules, are shown in chart 5. On the whole, satisfactory levels were obtained in most instances, but they were quite irregular. Some of the failures to detect penicillin in the serum during the first hour may have been due to the fact that the patient had

- CAPSULE A—315,000 UNITS, 1 HOUR LATER 90,000 UNITS THEN 90,000 UNITS EVERY 2 HOURS
- + CAPSULE B—300,000 UNITS, 1 HOUR LATER 100,000 UNITS THEN 100,000 UNITS EVERY 2 HOURS
- × TABLET C—120,000 UNITS, THEN 60,000 UNITS EVERY 2 HOURS
- TABLET C—150,000 UNITS, 1 HOUR LATER 90,000 UNITS THEN 90,000 UNITS EVERY 2 HOURS

Chart 5.—Serum levels obtained during oral penicillin therapy with various preparations and dosage schedules.

taken a meal shortly before the initial dose. Most of the serums in which penicillin could not be detected (that is, they contained less than 0.03 unit per cubic centimeter) after the first hour were from patients who received the smallest amounts of tablet C, namely 120,000 units followed by 60,000 units every two hours. The levels on the other dosage schedules are comparable, on the whole, with those obtained with a dose of 20,000 units given intramuscularly every three hours. The chief differences seem to be that with the latter method one is certain of obtaining significant levels during the first hour or two after each injection but not during the third hour,¹¹ whereas with the oral doses, even when given every two hours, the level at any time in any 1 subject cannot be predicted so long as food is taken during the treatment.

CLINICAL OBSERVATIONS

It seemed from these preliminary findings that the magnitude of the serum levels and the fluctuations obtained when the larger doses were given were not significantly different from those noted during intermittent intramuscular penicillin therapy with the doses which are most frequently and successfully used. Clinical trials with oral penicillin preparation in large doses, therefore, seemed justified. It was obvious, however, that only a rough estimate of the effectiveness of such therapy could be gained unless large numbers of cases could be studied with adequate clinical and bacteriologic control. Even greater numbers would, of course, be required for any reasonable comparison of different preparations or dosage schedules. This has already become clear from attempts to establish in cases of gonorrhea the curative dose of ordinary commercial penicillin given by intramuscular

injection.¹⁰ The present observations were therefore intended only as a test of the feasibility and general effectiveness of some of the preparations that were available.

Acute Gonorrhea.—A total of 61 patients were treated with various preparations and dosage schedules. Included are 5 patients who were given four doses of 25,000 units of ordinary penicillin in saline solution mixed with aluminum hydroxide gel. This method and dose had been suggested as giving complete and prolonged absorption. Two other patients are included, although, through a misunderstanding, they took only a single dose and left the clinic; but they returned for the follow-ups and were observed without further treatment. In general the total amounts were given in four to six doses, one or two hours apart. The patients were not all instructed to come to the clinic fasting, but about half of them had no breakfast or only a cup of coffee before the treatment was begun and the others had breakfast from one to two hours before the first dose. Most of them took a light meal after the third or fourth dose.

The results are listed in the table according to the criteria previously set forth. Since the duration of the treatment as well as the total dose may influence the result, both are shown in the table. It is seen that the majority of the cases were cured with each of the doses used and that probably doses of 450,000 units or more gave cure rates comparable to those usually reported from 100,000 units of penicillin given intramuscularly. That, however, cannot be stated with any certainty from this small number of cases. Clinically it was noted that, except with the largest doses used, the response of the individual patients to the oral therapy was not quite as good as that observed after the full intramuscular dose. With the former, some dysuria and mucoid or slightly purulent discharge continued for twelve to twenty-four hours longer in spite of the fact that organisms could not be seen on smear or obtained from cultures of the exudate after the last dose was

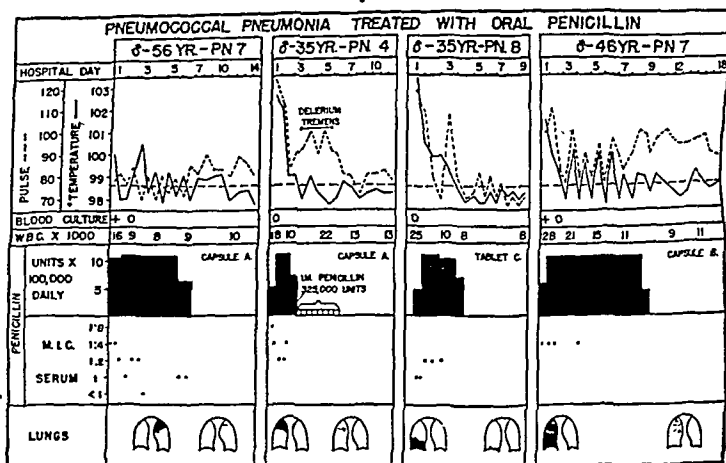

Chart 6.—Clinical course and certain relevant features in 4 cases of pneumococcal pneumonia treated with oral penicillin. The minimum inhibiting concentration of penicillin (M. I. C.) is shown in terms of dilution of serum (0.2 cc. amounts). In terms of Oxford units, 1 is equivalent to 0.03 unit, 1:2 = 0.06 unit, and so on.

taken. The cases which are listed as failures or probable recurrences all subsequently responded with complete clinical and bacteriologic cure after the usual doses of 100,000 units given in four intramuscular injections. Some of the serum levels obtained during treatment in these cases are shown in chart 5.

Pneumococcal Pneumonia.—The clinical course and some of the relevant findings in 7 patients with typical lobar pneumonia who were treated with oral penicillin are shown in charts 6 and 7. The disease was only of moderate severity in all, but 2 of them had positive blood cultures before treatment. Treatment was begun

UNTOWARD EFFECTS

Some of the control subjects and patients who received capsule A experienced slight abdominal discomfort accompanied by increased peristalsis, and they usually passed one or two loose and bulky stools, but none had any definite diarrhea. This may be attributable to the shellac. Both the crude and the ordinary commercial penicillin have a rather persistent and unpleasant taste which somewhat resembles that of licorice powder. There was also a mild odor of amylacetate to some of the preparations. No other untoward effects were experienced from any of the preparations.^{12a}

COMMENT

Two points stand out from the results of the serum levels obtained after single oral doses of penicillin. The first is the paramount importance of the time when a dose is given in relation to a meal. When the penicillin was taken one-half hour before breakfast, effective absorption was good and regular and this can probably be assumed for longer periods before the meal. When taken after the meal, the serum levels were irregular and unpredictable. Persons with achlorhydria had good serum levels for longer periods than normal persons when penicillin was given before a meal. When the penicillin was taken after the meal, absorption in the achlorhydric subjects was delayed and the serum levels were lower than when taken before a meal but were regularly higher and better sustained than in normal subjects. The importance of the size and of the various constituents of the meal as well as the duration of their effects has not been determined. These factors require further study, which should bring to light information that may be of practical importance in improving the results of oral therapy.

The second point which was quite striking was the fact that ordinary commercial penicillin powder when given in saline solution before a meal gives levels which are at least as high and as well sustained as the various preparations tested which contained buffers and stabilizers in tablets or capsules. This was generally true both before and after a meal with the possible exception

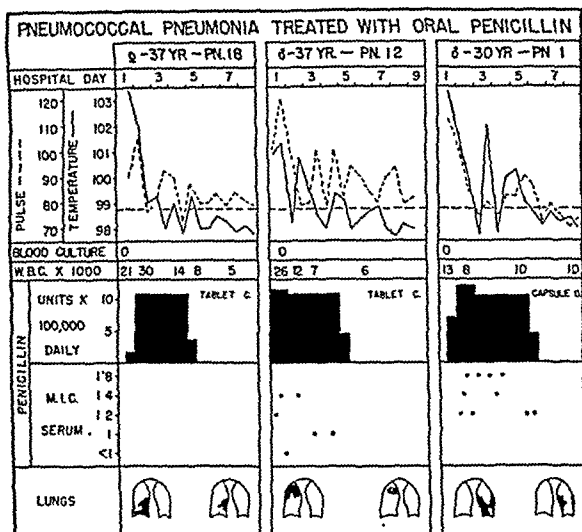

Chart 7.—Clinical course and certain relevant features in 3 cases of pneumococcal pneumonia treated with oral penicillin. The minimum inhibiting concentration and Oxford units are as in chart 6.

between the first and fourth days in 6 cases and on the seventh day in the remaining case. The initial dose was 300,000 units in 5 and 150,000 units in the other 2. The follow-up doses of 90,000 or 100,000 each were given every two hours thereafter and continued until the temperature had remained normal for about forty-eight hours. One patient developed delirium tremens after the temperature, pulse and leukocyte count had reached normal and he was clinically improved. A few intramuscular injections of penicillin were then given on that account. The total oral dose varied between 2.5 and 8.5 million units. The largest dose was used in a patient who had low grade fever for six days associated with an interlobar pleural effusion.

As seen from charts 6 and 7, the results are comparable with those obtained with effective sulfonamides given in full doses or with the usual doses of 15,000 units of penicillin given every two or three hours.¹² The patients were all clinically improved within twelve hours and were essentially afebrile in from twelve to thirty-six hours except in the case that was complicated by the pleural effusion. In the 2 cases in which blood cultures were positive before treatment, subsequent ones taken twelve hours later were negative. Studies of the sputum in these cases showed that pneumococci could not be recovered on the second day of treatment or later. In these respects too the results were comparable to those obtained with intramuscular penicillin therapy. The serum taken at various intervals usually showed complete inhibition of the test strain of hemolytic streptococcus either when used in 0.2 cc. amounts undiluted or up to a 1:8 dilution. These levels are equivalent to concentrations ranging from 0.03 to 0.22 unit per cubic centimeter of serum. Only rarely did the concentration fall below the lowest detectable level of 0.03 unit per cubic centimeter of serum.

Acute Gonorrheal Urethritis Treated with Oral Penicillin

* These patients left after an initial dose and received no other therapy but returned for a check up later.

of the aluminum hydroxide gel, which may have slightly increased and prolonged the absorption of the saline solution of penicillin when given after a meal.

The significance of the levels obtained from the single doses and during the course of treatment in the present study can best be appreciated by comparison with the

12. Meyers, M.; Harris, H. W., and Finland, M.: Treatment of Pneumococcal Pneumonia with Penicillin, *New England J. Med.* 232:747 (June 28) 1945.

12a In a recent case of pneumococcal pneumonia with bacteremia that was treated with oral penicillin alone a maculopapular rash developed on the fifth day and nitrogen retention (nonprotein nitrogen 165). These cleared within thirty-six hours after penicillin was discontinued.

in vitro penicillin sensitivity of various common pathogenic strains and with the levels obtained during routine treatment with the usual intermittent intramuscular doses. Data obtained in this clinic by the same or comparable methods are summarized elsewhere.¹³ A concentration of 0.03 unit per cubic centimeter was found to be sufficient in vitro to sterilize cultures of all strains of gonococcus and group A hemolytic streptococcus, the great majority of strains of pneumococcus and Streptococcus viridans, but only one half or less of the strains of meningococcus and Staphylococcus aureus. Most of the remaining strains of the two latter organisms and occasional streptococci from cases of subacute bacterial endocarditis required from two to eight times this concentration. Several of the staphylococci required even greater amounts. Thus, the levels obtained with the oral preparations in the doses used may be expected to prove effective in gonococcal, hemolytic, streptococcal and pneumococcal infections, but they may fail in many cases of staphylococcal or meningococcal infection and in some cases of subacute bacterial endocarditis.

The results in the clinical cases are obviously of a most preliminary nature. They do indicate, however, that treatment with penicillin given at brief intervals and in large doses is feasible and effective at least in cases which respond to low or moderate doses of parenteral penicillin. Obviously, clinical judgment dictates that the parenteral route is the preferable one for initiating treatment in all severe infections and for maintaining therapy in those infections in which large doses given over a long period have already proved essential for the best results.

SUMMARY AND CONCLUSIONS

A dose of 90,000 units of penicillin given by mouth one-half hour before breakfast regularly gave serum levels comparable with those obtained from 15,000 or 20,000 units given intramuscularly. The levels obtained in the serum when the same amount of penicillin was given one-half hour after breakfast were very irregular and unpredictable.

As compared with normal persons, achlorhydric individuals had more sustained serum levels from oral penicillin taken before a meal and higher as well as better sustained levels from the postprandial dose.

The serum levels obtained with ordinary penicillin in saline solution were at least as high and as well sustained as with any of the special oral preparations tested. This was true both before and after meals except possibly when aluminum hydroxide gel was used in addition to the saline solution of penicillin after a meal.

Effective penicillin levels could be fairly well maintained with several oral preparations given in 90,000 or 100,000 unit doses every two hours.

The results of preliminary clinical trials in gonorrhea and in pneumococcal pneumonia suggest that oral penicillin therapy is feasible in these infections. They suggest further that oral therapy should prove effective in other infections in which low doses of parenteral penicillin have proved adequate. Parenteral penicillin should be used to initiate therapy in all severe infections and in those which experience has already shown to require prolonged treatment with large parenteral doses.

THE TREATMENT OF PNEUMOCOCCIC PNEUMONIA WITH ORALLY ADMINISTERED PENICILLIN

PAUL A. BUNN, M.D.
WALSH McDERMOTT, M.D.
SUSAN J. HADLEY, M.D.
AND
ANNE C. CARTER, M.D.
NEW YORK

Several groups of investigators have demonstrated that it is possible to attain appreciable concentrations of penicillin in the blood following the oral administration of the material in various vehicles.¹ In a previous communication² it was reported that the height and duration of the blood penicillin concentrations observed in fasting subjects after oral administration are of the same order of magnitude regardless of whether the penicillin is administered following an antacid, as a suspension in oil, as a suspension in oil mixed with beeswax or in plain water. With any of these methods approximately five times as much penicillin is required to achieve a given blood concentration when the material is administered by the oral as by the intramuscular route. From the studies of urinary excretion there was no evidence that any of the vehicles promoted the absorption of more penicillin than occurred following the ingestion of the material in water. This original investigation has been extended to include a number of additional vehicles³ and methods for the oral administration of penicillin. These results will be reported elsewhere,⁴ but it can be said at this point that in no instance was it possible to demonstrate that any method was superior to the oral administration of powdered penicillin in a capsule or dissolved in water.

The present report is concerned with the therapeutic results attained following the oral administration of penicillin to a series of 45 patients with pneumococcal pneumonia. The patients were treated in the medical service of the New York Hospital and in the Second Medical (Cornell) Division of Bellevue Hospital. All patients in whom the diagnosis of pneumococcal pneumonia was established who were admitted to the two services during the period of study (December 1944 to May 1945) are included in the series (table 1).

VEHICLES AND METHODS OF ADMINISTRATION

Both the calcium and the sodium salts of penicillin were used. The former was given as a suspension in corn or cottonseed oil enclosed for convenience in a quick dissolving gelatin capsule.⁵ In a few instances the oil suspension of calcium penicillin was mixed with

5 per cent beeswax before it was capsuled. In about one half of the series (22 patients) the only preparation used was the sodium salt of penicillin in the customary powdered state enclosed in a gelatin capsule or dissolved in 20 or 30 cc. of iced tap water (table 1). Although the aqueous solution of penicillin is somewhat bitter to the taste, its administration caused little or no inconvenience to the patients. Three patients were treated solely with the aqueous solution of a preparation which contained approximately 90 per cent of the X fraction of penicillin.⁶

appearance of a crisis, the administration throughout the night was discontinued. From this point on the 50,000 unit doses were given from 8 a. m. to 10 p. m. inclusive.

With eight exceptions the duration of treatment varied from four to seven days.

No particular effort was made to arrange the timing of meals in relation to the administration of the penicillin despite the fact that the effectiveness of orally administered penicillin is appreciably diminished by the ingestion of food.⁶

DOSAGE REGIMENS

The dosage regimen was gradually modified throughout the period of the study. Because the effectiveness of the treatment was not established, the first patients treated received relatively huge amounts (1 to 2 million units) of penicillin during the first twenty-four hours of therapy. As experience was gained, it was possible to reduce the dosage, and the patients in the latter half of the series were all treated on a relatively constant regimen. This consisted in the initial administration of 200,000 units of penicillin followed by 50,000 unit doses at two hour intervals throughout the twenty-four hour period. Twenty-four to thirty-six hours after the

REACTIONS TO THE INGESTED PENICILLIN

No instances of nausea, vomiting, diarrhea or other gastrointestinal disturbances occurred following the oral administration of penicillin by these regimens. One patient developed mild generalized urticaria, which subsided promptly after the commercial brand of penicillin was changed.

PATIENTS

All of the patients presented the characteristic picture of pneumococcic pneumonia as determined by clinical

6 George, P., Vandegrift, H. N.; Elias, W., Collo, L. G.; Barry, I. M. and Pilcher, J. D. Administration of Penicillin by Mouth. Preliminary Report, J. A. M. A. 127: 632 (March 17) 1945. McDermott, Bunn, Bennett, D. J. and Haynes.

cal, bacteriologic and roentgenographic examinations. Although the pneumococcal infections observed by us during the study (1944-1945) were not so uniformly severe as in some previous seasons, all of the patients were acutely ill and 6 were in a critical state at the time of admission to the hospital. In almost one third of the group (13 patients) an initial bacteremia was present (table 2). Six patients were chronic alcoholic addicts who were intoxicated at the onset of infection. Of 3 patients with organic heart disease, 2 presented the characteristic peripheral evidence of congestive heart failure, and an additional patient was in severe diabetic ketosis when therapy was started.

AGE

The ages of the patients ranged from 15 to 89 years (table 1).

DURATION OF DISEASE AT START OF TREATMENT

As may be seen in table 1, treatment was started in the majority of instances within forty-eight hours of the onset of the pneumonia, as judged by the history of initial chill or first pleuritic pain. In a few patients

temperature to below 38 C. (100.2 F.) with accompanying signs of amelioration of the infection in the absence of peripheral circulatory failure. As may be seen in table 2, such a crisis developed within twenty hours in 11 patients, within thirty hours in an additional 19 patients and within forty-eight hours in 6 more patients. In 8 patients defervescence was not abrupt but developed gradually over a period of ninety-six hours.

No difference in therapeutic response could be demonstrated between the group of patients who received penicillin suspended in oil and those who received penicillin alone.

In chart 1 may be seen a representative example of the onset of crisis within twenty hours of the start of therapy with powdered sodium penicillin in capsules. This white man (W. N.), aged 58, was admitted to the hospital with a history of severe shaking chills, fever, pleuritic pain, nausea and diarrhea of twelve hours' duration. On examination he was found to be acutely ill, cyanotic and still shaking from a recent chill. Signs of consolidation over the area of the right lower lobe were demonstrable by physical and roentgenographic

the infection had undoubtedly been present for a longer period and in 1 instance therapy was not inaugurated until the fourteenth day of illness.

PNEUMOCOCCUS TYPES

In table 2 may be seen the distribution of the types of infecting pneumococci. The causative organisms in 18 patients (40 per cent) were in serologic types I, II and III. In 2 patients more than one type of pneumococcus was identified in the sputum, but in each patient a type I pneumococcus was the only organism demonstrable by culturing the blood and was considered to be the infecting pneumococcus. It was impossible to classify the organisms in 8 of the patients. In 6 of these an abundance of organisms with the characteristic morphology of pneumococci was present on direct examination of the sputum. Unfortunately, sputum for pneumococcus typing was not obtained from the remaining 2 patients. However, as the pneumonia of these patients both clinically and by roentgenogram was so similar to the picture of pneumococcal pneumonia observed in the others, these 2 cases have been included in the unclassified pneumococcus group.

RESULTS

In the majority of the patients a crisis ensued soon after the inauguration of oral penicillin therapy. The term "crisis" is used to designate an abrupt fall in

examination. Characteristic rusty sputum contained type I pneumococci. There was a leukocytosis of 25,000 cells with a decided increase in the numbers of immature forms, and the blood culture was sterile. Eighteen hours after the institution of therapy with penicillin powder there was an abrupt crisis. This remission of all signs of the infection was maintained, and at the end of seven days a roentgenographic examination disclosed almost complete disappearance of the pneumonia. The subsequent course was uneventful, with eventual complete recovery.

MORTALITY AND COMPLICATIONS

There was one death. The patient was a man aged 50, an alcoholic addict with hepatic cirrhosis who had been found in bed at home by neighbors with an acute illness of unknown duration. On admission to the Bellevue service he was critically ill with a pneumococcus type II pneumonia of the right upper lobe, fever of 40.2 C. (104.4 F.) and a bacteremia. He developed peripheral circulatory collapse with pulmonary edema and died six hours after admission. He had received 200,000 units of penicillin in water on admission and an additional 100,000 units subsequently. Postmortem cultures of the blood were not obtained, so that it is not known whether the treatment had had any effect on the bacteremia. Whether the administration of penicillin by another route would have proved more effective in

this case cannot be determined. However, the small number of fatalities from pneumococcic pneumonia which occur despite the intramuscular administration of penicillin usually develop in this type of case in which the development of shock results in death before there is sufficient time for the antibacterial agent to exert an effect.

Chart 1.—Onset of crisis eighteen hours after start of oral therapy with powdered penicillin (pneumococcus type I).

One patient developed empyema (chart 2). He was a student aged 21 who entered the hospital on the fourth day of illness. Examination revealed that he was acutely ill, with lobar consolidation of the right middle and lower lobes, cyanosis, dyspnea and fever of 40 C. (104 F.). A type V pneumococcus was found in his sputum, but there was no bacteremia. During the first twenty-four hours of treatment he received 850,000 units of penicillin in oil suspension. At the end of that period his temperature had fallen little and there had been only slight improvement in the clinical picture. As our experience with the treatment of pneumonia with oral administration of penicillin was so limited at the

Chart 2.—Pneumococcus type V empyema.

time of this patient's illness, it was decided to change to the intramuscular route. Within six hours of the change the patient's temperature had fallen to normal. Specimens of blood which were obtained during the period of oral administration were subsequently found to contain satisfactory concentrations of penicillin. Because of this finding, and the fact that the crisis occurred within such a short period after the change of route, it is probable that the abandonment of the oral

administration was an unnecessary caution. During the four days after the initial defervescence, while he was still receiving penicillin intramuscularly, the patient's temperature gradually rose and he was discovered to have a pneumococcus type V empyema. This was treated by aspiration and direct introduction of penicillin into the empyema cavity. During the next three weeks there was a gradual but slow resolution of the process in lung and pleura with eventual complete recovery.

A change of the route of penicillin administration from oral to parenteral was also made in 2 other patients in the series. In both of these cases, which were virtually identical, a low grade fever had persisted throughout the week after the initial crisis. In neither case was there any dramatic effect on the course of the fever following the change to intramuscular administration. The fever continued for a few days and then subsided gradually. The clinical course of 1 of these patients may be seen in chart 3. Other than these 3 patients, all the members of the series received the penicillin solely by the oral route throughout the entire period of therapy.

Chart 3.—Persistent low grade fever unaffected by change to intramuscular administration of penicillin (pneumococcus type VIII).

MINOR COMPLICATIONS

Eight patients developed small intrapleural collections of fluid demonstrable by roentgenogram during the course of their illness (table 2). These effusions were presumably sterile, as they resolved completely without aspiration.

"DELAYED RESOLUTION"

In 4 of these patients with effusions and in 4 additional patients resolution of the pneumonia was somewhat delayed. The designation "delayed resolution" is an arbitrary one and is used here to mean any residual, clinical or roentgenographic evidence of the process present later than twenty-one days after the onset of the infection. Four of these patients had not received therapy until after the fourth day of the pneumonia. From a clinical standpoint the course of all 8 of these patients with "delayed resolution" did not differ significantly from the other patients in the group. They were, however, kept under observation in the hospital for a longer period. Eventual complete recovery occurred in 7 patients between the third and the sixth week after onset of the pneumonia. One patient was lost from observation after the fourth week.

OTHER MINOR COMPLICATIONS

On admission to the hospital 1 patient presented an extensive pustular herpetic eruption of the lips and nose, and another had an acute but mild otitis media. In neither case was any special therapy required, and both infections disappeared as the pneumonias resolved.

FEBRILE RELAPSES

Twelve of the 36 patients who developed an abrupt crisis within the first forty-eight hours after the start of penicillin therapy showed a small secondary rise during the second or third day of therapy. This increase in temperature was usually to less than 38.6 C. (101.5 F.) but in 2 patients reached 39 C. (102.3 F.). In no instance was the fever accompanied by evidence of relapse of the infection. In 4 of these 12 patients the fever subsided promptly within thirty-six to forty-eight hours. In the remaining 8 patients the low grade fever persisted for four to seven days, and in 1 instance for fourteen days, before it subsided. An increase of the oral dose of penicillin in 1 patient and a change to the intramuscular route in 2 others did not seem to affect the course of this low grade fever, as mentioned previously (chart 3).

A more striking type of febrile relapse occurred in 5 patients at a two to five day interval after the cessation of penicillin therapy. In general, the peak of these recurring fevers did not exceed 38.5 C. (101.3 F.), but in 1 instance a temperature of 39 C. (102.3 F.) was attained. It was impossible to demonstrate by physical or roentgenologic examination that the return of fever was associated with a relapse or extension of the pneumonia. With some of the patients, however, the febrile recurrence was accompanied by an increase in leukocytes, and in a few instances it seemed as if there was an increase in cough without change in the amount or character of the sputum. This phenomenon of a return of fever after cessation of chemotherapy has been noted by others⁷ following the intramuscular administration of penicillin in pneumococcic pneumonia and will be discussed later.

Chart 4.—Secondary fever during therapy, and febrile relapse two days after cessation of therapy (pneumococcus type XVIII).

With the reinstitution of the oral administration of penicillin to 4 of these patients, the temperature and leukocyte count promptly returned to normal with no further relapse after subsequent discontinuance of therapy. The disappearance of the febrile relapse, however, was equally prompt in the other 2 patients who received

no penicillin during the period of recurrent fever. In this connection it should be noted that these febrile relapses occurred between the ninth and the seventeenth day of the pneumonia.

In chart 4 may be seen the clinical course of the patient who presented the most severe of these relapses. The patient was an alcoholic addict aged 48 who was desperately ill with a type XVIII pneumonia at the time of admission to the hospital. There was consolidation of two lobes, a bacteremia, abdominal distention and much difficulty in respiration, accompanied by cyanosis. After the initial crisis the patient's course was characterized by continued elevations of temperature, with two distinct rises to 38.8 C. (101.8 F.) on the third and fourth days of therapy. Following this, recovery was apparently progressing satisfactorily until the ninth hospital day (two days after cessation of penicillin therapy), when there was an abrupt return of fever accompanied by mild pleuritic pain, increase in cough and a moderate leukocytosis. All evidence of relapse disappeared promptly with the reinstitution of therapy, which was continued for a period of two days. The subsequent course was uneventful, with eventual complete recovery.

PREPARATIONS CONTAINING BEESWAX

As may be seen in chart 4, this patient received an unusually large amount (2 million and 50 thousand units) of penicillin during the first forty-eight hours of treatment. The reason for this is that during the first twenty-four hours of therapy he had received an oil preparation which was combined with 5 per cent beeswax. At the time of this patient's illness it was discovered from the studies of the pharmacology of orally administered penicillin which were proceeding concurrently with the therapeutic investigation that preparations of penicillin which contained beeswax are associated with erratic absorption and unpredictable blood penicillin concentrations. It was decided, therefore, to change to another preparation and to repeat the first day of the regimen. Only 2 other patients in the series received preparations containing beeswax. In both patients, however, therapy was initiated with 200,000 units of plain penicillin in water followed by the penicillin-oil-beeswax preparation. It is possible that the somewhat delayed crisis in the patient presented in chart 4 merely represented the severity of his infection and was not a result of irregular absorption of penicillin from the beeswax preparation. However, in the absence of a rapid method for the estimation of the concentration of penicillin in the blood, preparations for the oral administration of penicillin which contain substances which retard absorption should not be used in the treatment of serious infections until their reliability is established.

Chart 5.—Random determinations of blood penicillin concentrations per cubic centimeter in pneumococcic pneumonia. Circled points are levels from patient with pernicious anemia.

CONCENTRATIONS OF PENICILLIN IN THE BLOOD
DURING THE ACUTE ILLNESS

The penicillin concentrations attained in the blood at various intervals after oral administration were measured in 9 patients during the period of acute illness. The Kirby-Rantz modification⁸ of the Rammelkamp method of bioassay was used for most of the determinations, although a few were made by the original Rammelkamp technic.⁹ As performed in this laboratory the maximum sensitivity of the latter test is 0.078 unit per cubic centimeter, and of the former 0.04 unit per cubic centimeter in the detection of penicillin in an unknown specimen. In the majority of instances the specimens of blood were obtained after therapy had been in progress for some hours, and no attention was paid to whether the patient had recently ingested food. As a result, the determinations represent a random selection and some may reflect a cumulative effect.

As may be seen in chart 5, a blood penicillin concentration of 0.04 unit per cubic centimeter or higher was present at thirty and sixty minutes after a 50,000 unit dose in all but 2 patients. At 120 minutes after the same dose there was no detectable penicillin in the serum of 1 patient, but in the 4 others concentrations of 0.04 to 0.1 unit per cubic centimeter were present.

Only 3 patients were studied after larger doses (150,000 and 200,000 units respectively), and in 2 a relatively high penicillin concentration (0.1 to 1.0 unit per cubic centimeter) was present 120 minutes after administration; in the other there was no detectable penicillin in the blood sixty minutes after ingestion. The determinations enclosed in a circle (chart 5) were all made on specimens from a patient who had pernicious anemia. The higher levels attained in this patient may be a reflection of gastric anacidity. Unfortunately, only 1 patient was studied after the ingestion of penicillin in oil. The levels attained in this patient were of the same order of magnitude as were observed in others of the group.

In general, the penicillin concentrations observed in these acutely ill patients, although variable, were somewhat higher than is usually encountered following administration of the same oral dose to normal fasting subjects. The explanation of this phenomenon is not entirely clear. It is probable that several factors such as dehydration, accumulation of penicillin in the blood and variations in the effect of the infection on gastric and intestinal motility may play a role. It is equally possible, as discussed later, that under certain conditions, however, an infection could influence gastric motility in such a manner as to inhibit the absorption of ingested penicillin.

COMMENT

Forty-five patients with pneumococcic pneumonia have been treated by the oral administration of penicillin, with only one death and one serious complication. In the 3 instances in which the route of penicillin administration was changed from the oral to the intramuscular, it would seem that no additional advantage was gained. The therapeutic results were as satisfactory whether the penicillin was administered as a suspension in oil or merely as the plain powder dissolved in water or enclosed in a gelatin capsule. With both methods the penicillin concentrations attained in the blood of the patients acutely ill with pneumonia were

comparable or superior to those observed following the oral administration of similar amounts of penicillin to normal subjects.

The fact that the effectiveness of orally administered penicillin is impaired by the ingestion of food does not interfere with therapy. Virtually all patients with an acute pneumonia have not eaten for some hours before admission to the hospital. It was suggested that the meals served in the hospital might be spaced midway between two doses, but as no particular effort was made to enforce this recommendation it is probable that in the busy services it was not always carried out. In any event, at the most only three of the eight or twelve daily doses could have been affected by the ingestion of food.

A number of the patients presented a moderate degree of abdominal distention which did not seem to affect the therapeutic efficiency of the orally administered material. The absorption of ingested penicillin can be hindered, however, by inhibition of gastric motility.⁴ Therefore, if abdominal distention was accompanied by gastric dilatation, as is so frequently the case, it is probable that much larger doses of penicillin would be required for effective oral therapy. Until more information is available on this point, the presence of a moderate or pronounced degree of abdominal distention should be regarded as a contraindication to the use of penicillin by mouth.

A period of thirty to sixty minutes after ingestion is required for the attainment of the peak concentration of penicillin in the blood. Such a short delay would be of no significance in the treatment of most patients with pneumococcic pneumonia. In a critically ill patient with peripheral circulatory failure it is conceivable that even so short a period might be of importance. Under such circumstances, therefore, it would seem to be advisable to administer the initial dose of penicillin parenterally.

As previously mentioned, approximately four or five times as much penicillin must be given orally as intramuscularly to attain the same penicillin concentration in the blood. The regimens used in the treatment of this series of patients with pneumococcic pneumonia were calculated conservatively on the five to one ratio. Accordingly, the initial oral dose of 200,000 units is regarded as the approximate equivalent of 40,000 units intramuscularly and the subsequent 50,000 unit dose as the equivalent of 10,000 units. The administration of penicillin at two hour intervals by either of these regimens (oral or intramuscular) is usually followed throughout the greater part of the period by blood penicillin concentrations above a level (0.04 unit per cubic centimeter) which is presumably sufficient to inhibit most pneumococci.

Tillett, Cambier and McCormack¹⁰ have demonstrated that it is possible to treat pneumococcic pneumonia successfully by the intramuscular administration of penicillin in regimens which would not maintain detectable concentrations of penicillin in the blood continuously. In patients whose illness was of only moderate severity, these investigators¹¹ found that 10,000 units intramuscularly at three hour intervals for only four doses per day was a satisfactory regimen. In more severe infections they recommend an initial intravenous dose of 25,000 units, which is repeated at a three hour interval. Subsequent therapy consists of 10,000 units intramuscularly at three hour intervals, the

number of daily doses varying somewhat according to the condition of the patient. They recommend the initial larger doses in the more severe infections for the purpose of controlling the bacteremia and hence preventing metastatic complications.

The penicillin regimens used for the oral therapy of our series of patients with pneumococcic pneumonia were modeled in part after these intramuscular regimens studied by Tillett and his associates. The large initial dose to combat possible bacteremia and the omission of therapy throughout the night after the initial defervescence has been maintained are merely an adaptation of their systems to oral administration. The omission of penicillin therapy during a part of the night is undoubtedly a convenience to both patients and staff. Whether it is good chemotherapeutic practice in terms of the attainment of the maximum possible therapeutic result in the shortest period of time has not been established as yet. As far as could be ascertained in such a small series, the therapeutic results in the 6 patients in whom the night doses were omitted were identical with those obtained with the other members of the group.

Be that as it may, the return of fever and other minor evidences of infection in 5 patients after the cessation of penicillin therapy would indicate that all of the treatment regimens used in this series, although successful, were somewhat less than ideal. To be sure, the particular relapses observed were minor in character and were apparently without effect on the outcome of the disease. It is conceivable that this might not always be the case. Furthermore, a diagnostic problem is created. For the relapse, manifested by the return of fever and possibly by an increase in leukocytes, develops at a time when more serious complications such as empyema or endocarditis are most likely to make an appearance. To exclude the presence of such complications requires a reinvestigation of the case and the performance of laboratory tests, to say nothing of the worry occasioned the patient and the physician. The benign character of the relapse as distinguished from a complication is eventually made evident by the prompt disappearance of the former, either spontaneously or following the reinstitution of penicillin therapy.

This phenomenon of the return of signs of infection within a short period of the cessation of chemotherapy is by no means unique to the oral administration of penicillin. Several groups of investigators⁷ have noted the same phenomenon in the treatment of pneumococcic pneumonia by the parenteral administration of penicillin. Tillett and his colleagues¹² observed that the administration of large doses of penicillin in a single day to patients acutely ill with pneumonia produced a well defined remission of the signs of infection, which was followed within twenty-four or thirty hours by a relapse. In addition, these investigators¹¹ reported that, when penicillin was given over a four day period and then discontinued despite the presence of a low grade fever, the fever might continue for several days thereafter although the eventual result was perfectly satisfactory. In a few patients who continued to have fever for a longer period despite the continued intramuscular administration of presumably adequate amounts of penicillin, a change of chemotherapy to sulfadiazine was without noticeable effect on the rate of recovery, which was eventually complete. The latter cases of Tillett's are of interest in connection with the 2 cases reported

here in which the change from the oral to the intramuscular administration of penicillin exerted no apparent effect on the course of the persistent but eventually subsiding fever.

At Fort Bragg¹³ it was noted that in 57 per cent of a series of 75 patients with pneumococcic pneumonia treated with penicillin by the intramuscular route there occurred a transient increase in temperature in the period immediately following the initial crisis. Seven patients in the series showed a febrile relapse after cessation of therapy. However, all of the 7 had received small amounts of penicillin as part of an attempt to establish the minimal effective dose regimen for pneumonia. Despite the occurrence of the secondary fevers, the therapeutic results observed in this series were uniformly excellent.

Thus it is evident that with the penicillin treatment of pneumococcic pneumonia by either the oral or the intramuscular route there are two types of febrile relapses which occur in a minority of the patients. In one there may be a partial return of fever after the initial crisis despite the continued administration of the penicillin, whereas in the other the fever and minor signs of infection may return after the cessation of therapy in a previously afebrile patient.

The underlying mechanism of these phenomena has not been established. It is possible that the penicillin inhibits or destroys only the organisms in the heavily infected edematous zone at the periphery of the pneumonia but is unable to penetrate the exudate sufficiently to eliminate the pneumococci from the consolidated areas, in which case the destruction of the latter organisms would have to await the development of the normal cellular and immune forces in the host. In general, these mechanisms of immunity are not operating effectively until the fourth to the eighth day of the disease.

Further investigation of this problem should be pursued. In the absence of more exact information, however, and as the supply of penicillin is no longer so limited, it would seem that the duration of treatment in penicillin therapy of pneumococcic pneumonia, whether oral or parenteral, should be prolonged over a period well beyond that required for the attainment of maximum effectiveness of the natural defenses of the host. The patients treated in the latter part of the series presented in this report were accordingly treated for seven days or longer, depending on the duration or severity of the infection.

SUMMARY

1. Forty-five patients with pneumococcic pneumonia have been treated with the oral administration of penicillin with only one death and one serious complication, an empyema.
2. The therapeutic results in this series were comparable to those observed in the penicillin treatment of pneumococcic pneumonia by the intramuscular route.
3. Although relatively huge amounts of penicillin were used at the beginning of the study, the patients in the latter half of the series received 750,000 units on the first day and 400,000 to 600,000 units on the subsequent days of therapy.
4. It is believed that, in order to diminish the possibility of relapse, therapy should be prolonged for seven or more days, depending on the duration and the severity of the infection.

13. Kinsman, J. M.; Daniels, W. B.; Cohen, S.; McCracken, J. P.; D'Alonzo, C. A.; Martin, S. P., and Kirby, W. M. M.: The Treatment of Pneumonia with Sulfonamides and Penicillin, *J. A. M. A.* 128: 1219 (Aug. 25) 1945.

5. The therapeutic results obtained following the use of powdered penicillin dissolved in water or enclosed in capsules were as good as were observed after the administration of penicillin suspended in oil.

6. The concentrations of penicillin attained in the blood of 9 patients acutely ill with pneumonia after the ingestion of the aqueous solution, or the dry powder of penicillin (8 patients) or the oil suspension (1 patient) were comparable to or possibly higher than those usually attained after the same oral dose in normal subjects.

WITH THE TECHNICAL ASSISTANCE OF BETTIE

VIRGINIA PORTER, B.S.

WASHINGTON, D. C.

In 1941 Abraham and his associates¹ attempted to administer penicillin by the oral route and found that it was rapidly destroyed by the gastric acidity. These investigators employed phenyl salicylate coated capsules with relatively small doses of the drug but abandoned this method after unsuccessful trials. In corroboratory experiments Rammelkamp and Keefer² also demonstrated that penicillin was inactivated by the hydrochloric acid in the stomach. However, following intraduodenal administration, fairly adequate penicillin concentrations were demonstrated in the blood, approximating those achieved after intramuscular injection. In this regard Rammelkamp and Helm³ gave a penicillin solution containing 20,000 Florey units by mouth to 2 patients with achlorhydria associated with pernicious anemia and observed that the blood concentrations of penicillin were greater than those assayed in normal subjects.

In all of these preliminary experiments in which the oral route was used, comparatively small doses, ranging between 10,000 and 20,000 units, were administered. Antecedent neutralization of the gastric acidity by the use of sodium bicarbonate was attempted in some of these experiments, but in the majority of cases no effort was made to provide any mechanical protection for the conveyance of the penicillin to the small intestine.

The advantages of the oral route of administration of penicillin are obvious and require little elaboration when compared with the prevalent parenteral methods. Because of the rapid rate of excretion in the urine, frequent intramuscular or intravenous injections of

penicillin are required to maintain therapeutic concentrations in the blood. The inconvenience of such a regimen, both to the patient and to the hospital personnel, are manifest. Continuous intravenous infusions maintain a more constant serum level, but close supervision is necessary and the incidence of thrombosis is large enough to make the intramuscular route preferable.⁴ Furthermore, hospitalization is usually mandatory for the treatment of infections susceptible to penicillin when the parenteral route is employed.

Consideration of these difficulties has stimulated investigation of methods of prolonging therapeutic blood levels so that less frequent injections will be required. Toward this end, production of a kidney excretory blockade by diodrast⁵ or para-amino hippuric acid⁶ has been tried but does not seem practical for routine use. Similarly a combination of penicillin in a 3 per cent beeswax-peanut oil suspension⁷ for intramuscular use, as well as preliminary chilling of the muscle,⁸ has been employed to secure prolongation of therapeutic blood levels by decreasing the rate of absorption from the site of injection.

The greater availability of penicillin at the present time makes possible a reevaluation of the oral route of administration. In a preliminary report we⁹ demonstrated that adequate blood concentrations of penicillin could be obtained when penicillin is given by mouth. Several other reports employing various technics for oral administration have appeared in the recent literature; these include combination of the drug with mild antacids¹⁰ or suspension in oils¹¹ or raw egg solutions.¹²

The following report represents a preliminary clinical trial of the efficacy of penicillin when given by the oral route:

METHODS AND MATERIALS

To avoid inactivation, penicillin when given by mouth must escape the destructive influence of gastric acidity and be absorbed from the small bowel before meeting the inhibitory action of *Escherichia coli*.

For the purposes of these experiments the contents of an ampule containing 100,000 units of powdered sodium penicillin was transferred to a plain gelatin capsule (No. 1), which was moistened and sealed and in turn placed in a second capsule of the next larger size (No. 0). Hardening of the capsule containing the penicillin was then accomplished by placing it in solution of formaldehyde U. S. P. diluted 1:20 for five seconds, followed by immersion in 95 per cent alcohol for five minutes. The purpose of the double capsule was to provide additional mechanical protection for the penicillin in its passage through the stomach. Two aluminum hydroxide tablets¹³ were given one-half hour prior to the ingestion of each penicillin capsule in order to neutralize the hydrochloric acid in the stomach.

3. Rammelkamp, C. H., and Helm, J. C., Jr.: Studies on the Absorption of Penicillin from the Stomach, *Proc. Soc. Exper. Biol. & Med.* 54: 324 (Dec.) 1943.

From preliminary experiments⁹ the impression was gained that slightly higher penicillin blood levels were obtained when the capsules were taken on an empty stomach. In the clinical trials herein reported, a light diet with low fat content and moderate fluid intake was employed routinely. A three hour schedule of administration of the drug was followed, with slight adjustment of the diet schedule so that at no time was the penicillin capsule administered simultaneously with meals.

The subjects selected for these clinical trials included 14 children ranging in age from 2 to 11 years. There were 10 cases of gonorrhea, 2 cases of bronchopneumonia and 2 cases of cellulitis. Gonorrhea was particularly well suited for a clinical trial of the efficacy of the oral administration of penicillin because of readily demonstrable bacteriologic evidence of cure.

In cases in which penicillin assays were done while under treatment, samples of venous blood were taken at the end of one-half, one, two and three hours. Also, in 7 instances, penicillin levels were assayed during a consecutive six hour period to demonstrate the incremental rise in the blood penicillin concentration resulting from the ingestion of a second capsule three hours after the first dose.

his associates¹⁵ administered 315,000 Florey units of penicillin orally to four groups of fasting patients in four different forms: (1) penicillin in water, (2) in corn oil, (3) in water preceded by magnesium trisilicate neutralization of the gastric acidity and (4) in a 4 per cent beeswax-peanut oil mixture. In each instance

Chart 2.—Penicillin blood levels obtained in 3 children during a five to six and one-half hour period after a 100,000 unit capsule of penicillin. Note the concentration following ingestion of a second hours after the first dose.

Chart 1.—Comparison of penicillin blood levels after oral and parenteral administration.

Penicillin content was determined according to the method of Rammelkamp,¹⁴ using beta hemolytic streptococcus 203 as the indicator organism. Blood samples after withdrawal were immediately placed in the icebox and usually run within three or four days. It is advisable to assay the blood sample for penicillin content as soon as possible, since a certain amount of destruction occurs on standing, thus vitiating the accuracy of the level.

STANDARDIZATION OF PENICILLIN BLOOD LEVELS AFTER ORAL ADMINISTRATION

In a preliminary report on the oral administration of penicillin,⁹ single 100,000 unit capsules were given to normal adults. The average of six serum penicillin concentration curves obtained in these subjects are represented in chart 1 and comparison is made with the curves obtained after parenteral administration of between 40,000 and 45,000 units observed by Rammelkamp² and Romansky.⁷ It will be noted that the levels achieved after oral administration compared favorably and in some respects surpassed those observed after parenteral injection of approximately one-half the amount of penicillin. By comparison, McDermott and

serum penicillin concentrations of from 0.312 to 1.25 Florey units per cubic centimeter were obtained for thirty to sixty minutes after administration. From these results McDermott recommended an oral dose five times the amount used in intramuscular therapy.

However, it will be noted in chart 1 that, when 100,000 units was given, a double capsule being employed as a mechanical protection, an average level of 2.49 Florey units per cubic centimeter was obtained at the end of one-half hour and therapeutic levels were still demonstrable in the blood stream three hours after administration. It is possible that the use of only approximately twice the parenteral dose with this method, rather than the fivefold dose recommended by McDermott to achieve comparable results, is due in no

Chart 3.—Illustrating as in chart 2 the penicillin blood levels after ingestion of a 100,000 unit capsule and the increment obtained when a second 100,000 unit capsule is given at three hours.

small part to the use of mechanical protection for the penicillin afforded by a double gelatin capsule.

When 200,000 units as a single dose was given in a double capsule, higher levels of penicillin content in the blood were observed, ranging between 2.48 and 9.98

units per cubic centimeter one-half hour after ingestion. Therapeutic concentrations were maintained with this dose between four and five and a half hours, suggesting that blood concentration and prolongation may be directly proportional to the dosage employed.

Similarly, in the following clinical evaluation, a characteristic of the curves obtained in patients under treatment, after the oral administration of 100,000 units in a double capsule, was the relatively rapid appearance of large amounts of penicillin in the blood stream (charts 2 and 3). In the majority of instances the highest titers were observed in the first thirty to ninety minutes after ingestion, indicating prompt absorption from the small bowel. In 2 cases a somewhat delayed rate of absorption was obtained, as indicated by the appearance of a maximum concentration after two hours. Subsequent levels showed decreasing amounts during the next two hours. A feature common to all the curves was the continued presence of therapeutic serum levels of penicillin three hours after the ingestion of a 100,000 unit capsule. The highest penicillin serum levels ranged between 0.624 and 2.48 Florey units with one exception, when 0.156 unit was recorded. As may be noted in charts 2 and 3, the ingestion of a second

of oral penicillin could be calculated on the basis of weight. Further investigation is contemplated to establish the optimal dose by this method in both age groups.

In none of the cases included in this report were any objective or subjective symptoms of toxicity noted even after these relatively large doses. In 1 case, not included in this series, a total dose of 11,500,000 units was given over a period of fourteen days without toxic effect.

This method of administering penicillin has a wide range of applicability, especially in older children and adults. However, in some of the younger children it was necessary to place the capsule in the esophagus because of their inability to swallow the capsules spontaneously.

CLINICAL TRIALS

Gonorrhea.—Many reports have appeared in the recent literature concerning the efficiency of penicillin in the treatment of gonorrhea in adults. Observations on the value of penicillin for the treatment of this infection in children have been less numerous but equally satisfactory. There is general agreement that this drug is the most efficacious single agent for the management of this disease. It is curative for chemoresistant strains

Details of Treatment

Case	Sex	Race	Age, Years	Individual Dose of Oral Penicillin, Units	Dosage Schedule	Total Dose, Units	Interval Before Negative Culture, Hours	Days Negative	Comment
1	Q	W	4	100,000	Every 3 hours	300,000	12	4	Failed to respond to 200,000 units; subsequently cured with 300,000 units; 4 negative smears and cultures; no further clinic visits after discharge
2	♂	N	6	100,000	Every 3 hours	300,000	12	74	Failed to respond to 200,000 units; subsequently cured with 300,000 units; 6 negative smears and cultures
3	Q	N	8	100,000	Every 3 hours	400,000	12	35	Relapse after 300,000 units; subsequently cured with 400,000 units; 5 negative smears and cultures
4	Q	N	4	100,000	Every 3 hours	400,000	24	46	Cured; 9 negative smears and cultures
5	Q	N	3	100,000	Every 3 hours	400,000	12	40	Cured; 8 negative smears and cultures
6	Q	N	3	100,000	Every 3 hours	400,000	12	28	Cured; 5 negative smears and cultures
7	Q	N	3	100,000	Every 3 hours	400,000	12	66	Cured; 6 negative smears and cultures
8	Q	N	2	100,000	Every 3 hours	400,000	12	36	Cured; 6 negative smears and cultures
9	Q	W	7	100,000	Every 3 hours	400,000	12	26	Cured; 6 negative smears and cultures
10	Q	N	3	100,000	Every 3 hours	400,000	6	24	Cured; 4 negative smears and cultures

100,000 unit capsule produced an incremental curve in the penicillin titer similar to the initial three hour curve.

It may be concluded that, when these capsules are administered every three hours, therapeutic concentrations can be maintained constantly throughout the course of treatment for all susceptible infections.

Rammelkamp and Keefer¹⁶ found that the degree of antibacterial action was in direct proportion to the concentration of penicillin in the serum and found the maximum effects against *Streptococcus hemolyticus* to be in concentration of from 0.019 to 0.156 Florey unit per cubic centimeter of serum. Against staphylococci slightly higher levels were necessary, at least 0.156 Florey unit being required for maximum effect. Gonococci and pneumococci are both rated as highly susceptible organisms.

A comparison between the penicillin levels in children and adults observed after the oral administration of 100,000 units in a capsule reveals no especial difference. Interestingly, the curves noted in the two groups were similar in regard to concentration and prolongation. Adequate explanation for this observation is lacking, since theoretically one might expect higher and longer sustained levels in children if the dosage

of gonococci and has the additional virtue of being relatively nontoxic.

The current mode of administering penicillin by the parenteral route complicates the management of an otherwise ambulatory disease. The development of an adequate method of giving the drug by mouth has particular merit in the treatment of this and many other ambulatory infections, since it makes possible its management in office practice. Details of the treatment of 9 cases of gonococcal vaginitis and 1 case of gonococcal urethritis in children ranging in age from 2 to 9 years are presented in the accompanying table.

In view of the well known unreliability of smears alone as diagnostic criteria of gonorrhea, all the cases showed both positive smears and cultures before institution of therapy. Clinical cure does not necessarily coincide with bacteriologic cure; the criterion employed as used in the table was at least four negative smears and cultures obtained over a period of from three to four weeks after termination of treatment. The adequacy of this observation period is in agreement with the report of Lapenta and his associates.¹⁷ These investigators noted in their observations of 113 cases of gonococcal urethritis treated with intramuscularly

16. Rammelkamp, C. H., and Keefer, C. S. Penicillin: Its Antibacterial Effect in Whole Blood and Serum for the Hemolytic *Streptococcus* and *Staphylococcus Aureus*. *J. Clin. Investigation* 22: 649 (Sept.) 1943.

17. Lapenta, R. G.; Weckstein, A. M., and Sarnet, H. The Inadequacy of a Standardized Dosage of Penicillin in the Treatment of Gonococcal Urethritis. *J. A. M. A.* 128: 162 (May) 1945.

administered penicillin that not a single relapse occurred in a three month follow-up when three negative cultures were obtained over a period of twenty-one days.

The therapeutic index of this infection is directly proportional to several factors, viz. the sensitivity of the particular strain of gonococcus to penicillin, the duration of symptoms prior to starting treatment and the extent of the infection. In this regard there is a lack of unanimity of opinion in the literature regarding the optimal dosage of parenterally administered penicillin in the treatment of gonorrhea. Mahoney and his associates¹⁸ report only 74 per cent of cures after administration of 150,000 units intramuscularly. Lapenta¹⁷ reported 70 per cent cures with 100,000 units. These figures do not coincide with the greater percentage of cures reported by several other investigators who administered 50,000 to 100,000 units.¹⁹

In preliminary attempts to standardize the oral dosage required for gonorrhea, the first 2 patients treated were given 100,000 units at three hour intervals for two doses. However, this dosage failed to

Chart 4.—Penicillin blood levels obtained during a three hour period after the administration of 100,000 units by mouth in 3 cases of gonorrhea in children.

effect a cure. Three days later these 2 patients received 100,000 units for three doses and were cured. Similarly, the next patient was given three doses of 100,000 units, following which three negative vaginal smears and cultures were obtained. She was then discharged from the hospital but, ten days later, a follow-up smear and culture proved to be positive and a second course of oral penicillin consisting of 100,000 units every three hours for four doses was given with successful results. Following these preliminary reversals, it was clear that either the total dose of penicillin administered was insufficient or that treatment should have been continued for a longer time. It was therefore deemed

advisable to adopt arbitrarily a schedule consisting of 100,000 unit capsules given at three hour intervals for four doses. After the selection of this regimen no relapses occurred in the subsequent 8 cases.

The minimal dosage of oral penicillin for the treatment of this infection cannot be categorically defined. It is likely that cures could have been effected in the majority of cases with less than 400,000 units, especially if smaller single doses were given for a longer sustained period of treatment. However, it is believed that the employment of a larger dose than is considered necessary for every case would insure against symptomatic cures with the production of chronic carriers and prevent an increase in resistance of the strain of organism to subsequent treatment. It is clear that a much larger series of cases must be treated before any definitive statement can be made regarding the optimal oral dose.

Reference to chart 4 illustrates the penicillin concentrations obtained in 3 of these patients who were followed with serum levels during the course of treatment. In the curve obtained in subject 1, after oral administration of the first 100,000 unit capsule the blood concentration rose rapidly, attaining a maximum concentration of 2.49 Florey units per cubic centimeter at the end of one hour; after three hours a level of 0.624 Florey unit per cubic centimeter was still demonstrable. In subjects 2 and 3, maximum levels of 0.624 and 1.24 Florey units per cubic centimeter respectively were obtained one-half hour after oral administration of the 100,000 unit capsule, followed by a moderately rapid parallel fall in both instances with 0.078 and 0.039 Florey unit per cubic centimeter still present after three hours. It will be noted that in all three curves the penicillin levels taken at frequent intervals during the three hour period were all well within or above the therapeutic range of penicillin against gonococci. The degree of antibacterial action of penicillin has been shown to be directly related to the concentration of penicillin in the blood; as previously noted, the maximum effects of penicillin against gonococci are obtained when blood concentrations range from 0.019 to 0.156 Florey unit per cubic centimeter.

Reference to charts 2 and 3 illustrate the incremental elevations obtained when a subsequent 100,000 unit capsule is given at the end of three hours. It may be inferred that similar rises in the penicillin blood levels would be present with each additional three hour dose. From this one may postulate the presence of therapeutic concentrations at any instant throughout the nine or twelve hour period during which therapy is maintained.

As noted in the table, a bacteriologic cure was effected within six to twenty-four hours after the institution of therapy with the majority of cases showing no organisms after twelve hours.

A rather consistently close parallel in the serum penicillin values at comparable intervals in both children and adults was observed following the ingestion of 100,000 unit capsules even though on a theoretical basis some disparity in the penicillin concentrations might be expected when identical dosage is given to the two age groups. Although the cures reported here deal with gonorrhea in children, the employment of the same schedule of 100,000 unit capsules given every three hours for four doses would probably be similarly efficacious. However, this remains to be proved by clinical trial in a series of gonorrhea in adults.

Pneumonia.—Two cases of pneumonia were treated by the oral administration of penicillin. Case summaries follow:

CASE 1 (chart 5).—J. B., a Negro girl aged 7 years, was admitted to Children's Hospital with a history of fever, chills and productive cough of six days' duration. Two days after the onset of illness she was seen by her local physician and was given 2 Gm. of sulfadiazine a day. Therapy was continued during the subsequent four days without any improvement being noted. On entry into the hospital, sputum examination revealed pneumococcus type XIV, and an x-ray of the chest confirmed the clinical impression of right lower lobe pneumonia. Blood culture was negative. Oral penicillin therapy was started and consisted of 100,000 unit capsules every three hours for ten doses, totaling 1,000,000 units.

Twelve hours after the initiation of treatment, her temperature dropped precipitously from 105 F. to 98.4 F. and she remained afebrile during the remainder of her hospital stay. This was followed by clinical evidence of resolution of the pneumonic process during the next two to three days. A chest film taken three days after termination of therapy was negative. Likewise the white blood cell count dropped from an initial 23,000 on entry to 5,400 within two days, and pneumococcus organisms were no longer demonstrable in the sputum after forty-eight hours.

Six samples of blood were taken over a consecutive six hour period while the patient was under treatment and assayed for penicillin content. As may be noted in chart 5, adequate amounts of the drug promptly appeared in the peripheral blood after the ingestion of the capsule and was maintained for three hours. When the second capsule was taken at the end of three hours, therapeutic concentrations were maintained and prolonged for another three hour period. The amounts present

ished breath sounds over the right lower lobe. X-ray examination showed an infiltrative lesion in the right base indicative of pneumonia. Two sputum cultures showed *Staphylococcus aureus* hemolyticus.

The patient was given 100,000 units of penicillin orally every three hours for eight doses, totaling 800,000 units, with a defervescence of fever from 103.8 F. to 97.4 F. twelve hours

Chart 6.—Observations in case 2.

after the initiation of therapy. The temperature remained normal, with resolution of clinical and x-ray signs in three days (chart 6).

Further trials of oral penicillin therapy for the treatment of pneumonia are now under way. As in the management of gonorrhea, the establishment of an optimal oral dose necessitates an extensive clinical evaluation. In the reported 2 cases, 800,000 and 1,000,000 units given over a period of twenty-four and thirty hours produced a rapid response and cure.

Cellulitis.—Two cases of cellulitis of the face were treated with oral penicillin. One patient, a boy aged 11 years, had an extensive involvement of the left side of his face and neck secondary to an infected tooth. He was given 100,000 unit capsules every three hours for twelve doses and showed a prompt effective response, with rapid subsidence of inflammation and swelling in forty-eight hours. The second patient, a child aged 7 years who had periorbital cellulitis associated with suppurative ethmoiditis, also received a thirty-six hour course of oral penicillin consisting of 100,000 units every three hours. A similar prompt recovery ensued forty-eight hours after the initiation of therapy.

CONCLUSIONS

1. Adequate therapeutic blood concentrations of penicillin after oral administration can be obtained when the drug is protected against inactivation by gastric acidity. A method of providing this protection by the use of a double gelatin capsule hardened by formaldehyde-alcohol immersion together with prelimi-

Chart 5.—Observations in case 1.

ranged between 0.078 and 1.24 Florey units per cubic centimeter during this interval.

CASE 2 (chart 6).—R. H., a Negro boy aged 7½ years, was admitted with the chief complaints of abdominal pain and fever. The temperature on admission was 100.4 F., rising four hours later to 104 F. Pronounced dyspnea, with splinting of the right side of the thorax, was noted. Examination of the chest revealed dullness on percussion, crepitant rales and dimin-

nary neutralization of the hydrochloric acid in the stomach was adopted.

2. Administration of a 100,000 unit capsule every three hours by this method provides constant therapeutic penicillin levels well within or above the effective antibacterial range of most susceptible organisms throughout the course of treatment.

3. A clinical trial of this method on 10 children with gonorrhea, 2 with pneumonia and 2 with cellulitis resulted in prompt recovery.

4. The relatively large doses of penicillin employed produced no toxic manifestations.

BORIC ACID

A DANGEROUS DRUG OF LITTLE VALUE

E. H. WATSON, M.D.

ANN ARBOR, MICH.

Many indispensable drugs are known to be dangerous when used in improper dose or by unusual routes of administration—digitalis, iodine and others immediately come to mind as illustrations. Certain toxic drugs—arsenicals, for example—continue in use because of their effectiveness and because nontoxic substitutes of proved effectiveness are lacking. It cannot sensibly be argued that an effective drug should be dropped from use simply because the occasional patient reacts unfavorably to the ordinary dose or because untoward reactions follow the accidental administration of an excessive dose. When, however, a drug can be shown to be almost entirely ineffective and at the same time dangerous even when used in ordinary ways, it is time to remove that drug from general use as rapidly as possible. Boric acid is such a drug.

Search of medical literature reveals many instances of accidental poisoning with boric acid and not a few following its calculated use in ointment and powder form.¹ Fatal poisonings have been reported following the placing of boric acid powder into wounds and boric acid solution into the bladder,² the empyema cavity³ and the bowel,^{3a} and unreported instances of death following its use in the stomach in gastroscopy have come to our attention. Both the powder and the solution have caused death when they were accidentally administered in food. A recent occurrence of this kind, according to newspaper reports, involved poisoning of 19 infants in a New Jersey hospital, with fatal results in 4. At about the same time Dr. R. R. Cross, director of public health of Illinois, requested hospitals to eliminate boric acid from the inventory of drugs kept on hand for use in maternity divisions.⁴ This request is reported to have followed the death of 2 infants in an Illinois hospital, attributed to boric acid poisoning. Boric acid

preparations were removed from use in the children's ward of University Hospital (Michigan) several years ago following the fatal poisoning of an infant:

A. B., a white boy aged 4½ months, was admitted to the hospital because of very severe infantile eczema. Almost all of the body was involved in a typical, acute cracking and weeping eczema. Except for this the infant showed normal growth and development, and physical examination revealed no other deviation from normal.

Initial treatment consisted in continuous warm wet dressings of saturated boric acid solution applied to the entire body. The infant was restrained to prevent scratching. Colloidal baths were given twice daily. By the second day of this treatment the skin had improved considerably, several areas being ready for application of ointment. It was our custom then as now to use crude coal tar in 3 per cent strength, Lassar's paste being a commonly used base for the tar. Because one member of the staff had seen good results in treating less severe eczemas with boric acid ointment in another hospital, its use in place of tar ointment was decided on. Orders were to apply boric ointment twice daily to all inflamed areas which were not crusted or weeping. Only three general applications were made, a total amount of ointment somewhere between 60 and 100 Gm. being used. Twenty-four hours after the first application of boric acid ointment the temperature rose to 102 F. and two hours later the patient began having convulsions while receiving a colloidal bath. These convulsions lasted for about three hours, during which time the temperature rose to 107 F. They were controlled at the end of this time by codeine but were resumed again at intervals throughout the next few days. The most striking thing about the case during this time was the development of an intense and generalized erythema. This was so pronounced that the child was literally the color of a boiled lobster. Almost from the beginning of the convulsive seizures the eyes were wide open and staring but they did not follow a light, the corneal reflex was present, and the ocular fundi were normal. It was evident that he soon became deaf.

During the course of the week following the onset of convulsions the seizures gradually became fewer. Between convulsions the child apparently existed in a vegetative state. It was in a deep coma from which it could not be aroused. It remained in this condition until the time of its death, which occurred approximately three weeks after the onset of convulsions. Intravenous glucose, blood transfusions, feeding by gavage and other types of supportive treatment were tried, the only result being that the child remained alive.

Shortly after the first convulsion a lumbar puncture was done. This revealed an increase in pressure of the spinal fluid, 3 cells, total protein of 113 mg. per hundred cubic centimeters, 4 plus globulin and a colloidal gold curve of 000110000000. Lumbar punctures at one week and two weeks after the onset of convulsions were essentially normal, the cell count in 1 instance being 5 and the other not recorded.

Diagnosis of boric acid poisoning was first made when it was noted by a member of the staff on the second day following the onset of convulsions that the child resembled and behaved in a manner similar to 3 infants accidentally poisoned with boric acid solution in a New York hospital. In this instance 3 infants were given saturated boric acid solutions (parenterally) by mistake when it was intended to give isotonic solution of sodium chloride. All of these infants died, the most remarkable thing being the *boiled lobster* appearance of the skin. Practically all reports of boric acid poisoning which have appeared in the literature have remarked about this significant feature. Accidental poisoning similar to that in the New York hospital also occurred in a Chicago hospital infants' ward about twenty years ago. In this instance several infants were given boric acid solutions by mouth and nearly all of them died. This was not reported in detail in medical literature, but reports of the pathologist's examination at the postmortem have been published.⁵

Tests for boric acid on the spinal fluid and urine of our patient were strongly positive on three occasions but were no longer positive after one week. The turmeric test for boric acid was used.⁶

As already stated, the patient remained alive for approximately three weeks following the onset of the boric acid poisoning. During this time several spinal fluid examinations and other clinical observations indicated the absence of infection. However, on the third day preceding death there was an elevation of temperature, and a lumbar puncture done two days before death revealed a spinal fluid cell count of 185. Autopsy was obtained which showed the final cause of death to be lobular pneumonia and purulent meningitis (pneumococci). Other postmortem diagnoses were generalized septicopyemia, fatty atrophy of the liver, extensive cloudy swelling of the kidneys and exfoliative dermatitis of the face and neck. It seemed quite clear that the pneumococcosis found at postmortem examination was a terminal invasion.

Our primary diagnosis of boric acid poisoning in this case was based, not so much on the finding of boric acid in the spinal fluid and urine of the patient, for we were subsequently able to show that the boric acid saturated dressings applied to a very small area of excoriation was sufficient to give a positive test for boric acid in the urine when an alcohol solution of turmeric was used, but more on the fact that the patient's appearance, symptoms and clinical course resembled known cases of boric acid poisoning. We had applied fairly large amounts of U. S. P. boric acid ointment, possibly as much as 100 Gm. (containing 10 per cent of boric acid) to extensive areas of broken skin, which furnished ideal conditions for its absorption. Apparently sufficient had been absorbed to cause a fixed acidosis and irreparable damage to the central nervous system, immediate evidence of this damage being convulsions, blindness and deafness and an increase in pressure and albumin in the spinal fluid.

COMMENT

With the advent of considerably more effective germicides, use of boric acid or its solutions has almost ceased. Probably the principal uses of boric acid or its solutions are in the eye and for irrigating body cavities. Both of these uses have been abandoned in the University Hospital. Boric acid solution as ordinarily used in collyria is probably without significant antiseptic or germicidal properties—many newer antiseptics are far superior to it. As a lavage to remove exudate (pus) from the eye a weak solution of sodium bicarbonate is much more effective.

Boric acid solution is widely employed by mothers of small infants in the care of the eyes. Freshly boiled and cooled water will do as well and has only the drawback of needing to be freshly prepared daily, whereas boric acid solution usually remains sterile on standing, though some organisms will survive in it for a significant time. Another use of boric acid solution is to cleanse the breasts of the mother before putting the infant to breast. Lembcke⁷ has clearly shown the danger of relying on the supposed bactericidal properties of boric acid solution in this connection. He has reported an outbreak of diarrhea in a newborn nursery and shown that the probable pathogenic organism was transmitted from infant to infant by way of the boric acid solution soaked cotton pledgets used to sponge the breast before feeding. In the early part of World War II boric acid ointment was officially suggested as a dressing for burned areas of skin. This suggestion was later withdrawn—a wise decision, it would seem, in view of the demonstrated ease with which the damaged skin may absorb drugs. In 1910 Rubin and

Donner⁸ called attention to the rapid absorption of boric acid from denuded areas such as burns.

The following quotations from recent editions of three widely used textbooks on pharmacology indicate the fallacy of depending on boric acid to act as a bactericide or a significant bacteriostatic:

Sollmann,⁹ speaking of boric acid and sodium borate (borax), says "These are fairly antiseptic, but not potently germicidal, and it is questionable whether they check bacteria under clinical conditions. They are not deleterious locally or systemically in the amounts ordinarily used, but larger doses are fatal."

Elsewhere Sollmann says "Death may result from the ingestion of 15 to 30 Gm. of borax or 2 to 5 Gm. of boric acid. This has occurred by intravenous injection of boric acid solution in mistake for saline or by similar mistakes in infant feeding. It may arise from local administration (van Dort Krom, 1906); especially from flushing cavities and from use of powdered boric acid on extensive burns (Savariaud, 1914)."

Edmunds and Gunn¹⁰ state that "boracic acid and its sodium salt have some antiseptic power, for in 2.5 per cent solution almost all forms of bacilli stop growing; but they are not destroyed, even the delicate anthrax bacilli being found capable of further growth after exposure to a 4 per cent solution for twenty-four hours. Boracic acid is therefore valueless as a disinfectant but has been used as an antiseptic dressing; it has the advantage over many other antiseptics of inducing very little irritation and of being only slightly poisonous, but experience has shown that it cannot be used with impunity in very large quantities. . . . Chemical examination of the organs in cases of fatal poisoning has shown that the largest amount of boracic acid is stored in the brain, which in turn is followed closely by the liver."

Goodman and Gilman¹¹ state that "boric acid is a very weak germicide, and certain organisms such as *Staphylococcus aureus* are not killed by long exposure to a saturated aqueous solution. However, aqueous solutions are effective in inhibiting bacterial growth. . . . Although it is not very toxic, serious poisoning can result from the ingestion of 5 Gm. of boric acid."

SUMMARY

A case of fatal boric acid poisoning following use of boric ointment U. S. P. in eczema was observed. Use of boric acid preparations should be discouraged because of their limited usefulness and the real dangers of their accidental and intentional use. The medical profession as a whole probably puts unwarranted confidence in boric acid preparations and is likely to forget that boric acid is a poison.

PAROXYSMAL TEMPORAL HEADACHE

SAMUEL B. NADLER, Ph.D., M.D.
NEW ORLEANS

Within the past year I have treated 8 cases of headache so closely related from the standpoints of clinical manifestations and therapeutic response that a report seems warranted.

The characteristic picture was one of periodic attacks of throbbing pain in the right, left or both temporal regions radiating to the frontoparietal and postauricular areas. Although throbbing pain predominated and was frequently "unbearable," it was usually superimposed on a dull, constant ache in the involved parts. Attacks ranged in frequency from once a month to several times a week over a period of months or years, usually recurred in the same region (right or left temporal) and lasted from several hours to several days. Onset was abrupt, appeared any time during the day and was apparently unrelated to physical exertion or emotional tension.

Gastrointestinal manifestations were common but tended to accompany the headache rather than precede it. Scotomas, dizziness, facial flushing and rhinorrhea did not occur. Sensitivity to histamine by skin test was demonstrated in only 1 case.

Digital compression of the temporal artery on the affected side abolished the throbbing pain and most of the continuous dull ache. The point at which digital compression afforded maximum relief was located; the tissue about the segment of artery underlying the palpating finger was infiltrated with 2 cc. of 1 per cent procaine hydrochloride. This procedure effected complete disappearance of the throbbing and almost complete cessation of the dull aching pain. Periarterial infiltration with 2 cc. of isotonic solution of sodium chloride used as a control in all cases invariably failed to alleviate distress.

Relief was frequently obtained within one minute after periarterial block with procaine hydrochloride and lasted from several hours to several days. In the latter instance it is probable that the attacks were aborted rather than relieved by prolonged anesthetization.

Of the 8 patients, 5 with frequently recurring headache obtained complete remission following arterial section. Patients were followed postoperatively from two to eleven months. A general anesthetic was used in 3 instances and a local in 2. Arterial biopsy in 3 cases disclosed no abnormal changes in the vascular walls. Three patients whose attacks occurred less frequently preferred repeated block with procaine hydrochloride to surgical intervention.

REPORT OF CASES

CASE 1.—B. W., a white woman aged 21, single, referred by Dr. C. H. Weinberg on May 15, 1944, had been incapacitated by periodic headaches occurring two or three times a month to such an extent that for three years she had been unable to retain steady employment. The headaches were almost entirely limited to the temporal and parietal regions on the right side and were characterized primarily by a dull ache with exacerbations of sharp, shooting, throbbing pain lasting several hours. The duration of the attacks was from two to five days. Nausea occurred frequently, but there were no visual disturbances. During attacks the patient occasionally experienced a sensation of warmth on the involved side. At first the headaches usually appeared about the time of the

menstrual period but during the past year and a half occurred at any time.

Physical examination yielded essentially negative results. Routine laboratory studies failed to reveal any abnormality. The result of the skin test for histamine sensitivity was negative.

When first seen the patient had a headache of one week's duration. Pressure over the right temporal artery immediately obliterated the throbbing pain, leaving only a slight dull headache in the temporoparietal region. Periarterial infiltration with procaine hydrochloride completely relieved the pain for twelve hours, after which throbbing in the right temporal region recurred. Periarterial infiltration with saline solution had no ameliorative effect; infiltration with 2 cc. of 1 per cent procaine hydrochloride produced arrest of the pounding headache.

Ligation and section of the temporal artery performed by Dr. Sidney Copland on May 19 resulted in disappearance of the headaches to date.

CASE 2.—J. R. C., a white man aged 55, referred by Dr. Gilbert Anderson, had suffered from temporal headaches about two or three times a month for one year. Seizures lasted several hours and were readily abated by various "headache remedies." There were no other associated symptoms.

One such severe bilateral throbbing headache occurred on April 17, 1944; its intensity did not diminish during the next ten days, and the patient had not been able to sleep for several days. Nausea and vomiting complicated the picture. When seen in consultation on April 27 he was in obvious pain, restless, dehydrated and exhausted. He reiterated the statement "The headache is driving me crazy." Pain was located chiefly in the temporal region but radiated into the frontal, parietal and posterior auricular portions.

Physical examination disclosed nothing of importance; the blood pressure was within normal limits, the temporal arteries were tortuous, and visible pulsations were readily detected. Digital compression to obliterate the pulsation allayed throbbing on the affected side. Bilateral infiltration with procaine hydrochloride relieved all pain, but a mild, dull residual headache remained. The patient promptly fell asleep.

Cephalalgia gradually returned during the succeeding hours and reached its former peak intensity in twenty-eight hours, at which time saline infiltration failed to produce relief. Bilateral block with procaine hydrochloride again effected subsidence of the throbbing pain. Ligation and section of both temporal arteries was done by Dr. Gilbert Anderson on April 20, and the patient has been free from symptoms since that time.

CASE 3.—M. B., a white man aged 36, seen on Sept. 3, 1944, complained of periodic headaches for the past two and one-half years. They occurred chiefly on the right side, were throbbing in character and ranged in frequency from three to five attacks a month. On September 6 the patient was seen during a typical seizure and obtained relief from digital compression and periarterial infiltration with procaine hydrochloride. A subsequent attack three days later was again mitigated by the same procedure. On September 6 ligation and section of the right temporal artery was done; the patient has had no headaches since that time.

CASE 4.—B. R., a white woman aged 42, married, seen on Sept. 16, 1944, complained of a throbbing headache in the right temporal region occurring six to eight times a month for the last two years. Beneficial response was obtained from periarterial infiltration with procaine hydrochloride. Ten days later another attack again responded to periarterial infiltration, but the pain recurred about two hours after injection. The patient has had no headache since ligation and section of the right temporal artery, performed on Sept. 28, 1944.

CASE 5.—G. A., a white woman aged 27, married, consulted me on Jan. 15, 1945 because of right temporal headaches occurring ten or twelve times a month for a period of approximately three years. The attacks lasted from several hours to several days and were associated with nausea and vomiting. There were no other noteworthy symptoms. From time to time ergotamine tartrate had been used successfully.

The patient was seen during a characteristic attack on January 17 and responded promptly to digital compression and periarterial infiltration with procaine hydrochloride. On February 8 the patient appeared again for relief of a typical right temporal headache; alleviation was again secured by periarterial infiltration with procaine hydrochloride. Dr. Sidney Copland performed ligation and section of the right temporal artery on February 15, and cephalalgia has not occurred since that time.

In a study on the mechanism of migraine, Graham and Wolff¹ reported highly significant observations on 16 patients. They discovered a close relationship between the amplitude of pulsations in the extracranial arteries and the intensity of the headache. Reduction in the amplitude of pulsations in the temporal artery (during an attack) by the administration of ergotamine tartrate or by digital compression diminished or abolished the headache. In 4 patients the pain was limited to the distribution of the temporal and occipital arteries and could be completely abolished by digital pressure sufficient to obliterate arterial pulsation.

Other branches of the external carotid artery may be involved. Dickerson² pointed out that in certain cases the migraine could be abolished by ligation and section of the middle meningeal artery on the affected side. Patzer, Derbes and Engelhardt have obtained relief in certain cases of migraine by periarterial infiltration with eucupine and procaine hydrochloride.³

Six of the 8 cases in this series had previously been diagnosed as "migraine" on the basis of periodic attacks of intense hemicranial cephalalgia, accompanied by nausea and occasionally by vomiting. It is not surprising that none of the patients had visual disturbances, since the end-organ artery was extracranial. Cases of "migraine" involving arteries other than the temporals have been omitted from this series.

Selection of cases of paroxysmal temporal headache was made on the basis of a typical history of periodic throbbing headache limited to the distribution of the temporal artery and its main branches, with relief by digital compression of the artery and by periarterial infiltration with procaine hydrochloride. In order to test adequately the criteria for selection the patient should be seen at the peak of an attack. If relief is obtained on two or more occasions by infiltration with procaine hydrochloride (with control saline injections) ligation and section of the affected temporal artery seems justified. Injection with procaine hydrochloride between attacks is ineffectual. The results reported in this paper seem to indicate that this particularly distressing headache is amenable to surgical intervention, with the possibility of prolonged or permanent cure. There is no evidence to date (two to eleven months postoperatively) that the factor or factors inducing segmental arterial dilatation in the surgical cases are predisposed to affect other extracranial vessels of these patients.

SUMMARY

Operative intervention has been successful in the abolition of paroxysmal temporal headache in 8 cases for the observed period of two to eleven months postoperatively. Cases of "migraine" satisfying the criteria may benefit from operation.

1430 Tulane Avenue.

RECENT FRACTURES OF THE CARPAL SCAPHOID

LIEUTENANT COLONEL RALPH SOTO-HALL
MEDICAL CORPS, ARMY OF THE UNITED STATES

Fractures of the carpal scaphoid offer a great challenge to the surgeon, for on his skill in diagnosis and treatment rests the ultimate functional result. The treatment of recent fractures of this type is almost a solved problem, as shown by the many studies of end results in the last few years. But too many surgeons fail, either because they are not vigilant in noting and following the most minute details in diagnosis and treatment, or because they experiment with methods which are not founded on sound anatomic principles.

DIAGNOSIS

This fracture must be diagnosed immediately after the injury, and failure to do so is one of the main causes of nonunion. A note of warning must be given about diagnosis of so-called severe sprain of the wrist, too often made because of negative roentgenograms, and it is a good working rule to deny its existence. Injuries to the semilunar or scaphoid often simulate this condition and thus fail to be recognized, and since precious days are allowed to pass without the instituting

Fig. 1.—Experimentally produced fracture of the carpal scaphoid in a cadaver. A wire has been threaded through the flexor pollicis longus tendon. These views show the intimate relationship of this tendon to the scaphoid, particularly to the area of the tubercle. In these specimens any movement of the interphalangeal joint of the thumb produces a definite change of position of the fractured fragments. The tendon passes beneath the transverse carpal ligament and entering the osseoponeurotic canal, of which the scaphoid is a wall, then passes distally to be inserted in the distal phalanx of the thumb. Note that in the anteroposterior view the fracture is not visible, whereas in the oblique view it is readily seen.

of correct treatment the surgeon's oversight may be, to the patient, an economic catastrophe.

A history of a fall on the outstretched hand, tenderness in the anatomic snuffbox and pain there on percussion of the fully extended thumb should be almost conclusive evidence. Should the initial x-ray fail to show the fracture, the clinical findings should be used as presumptive evidence, and the only course to be followed is immobilization of the wrist for a period of three weeks. After this, should radiographic studies again be negative, the patient's ligamentous injury will have been helped by rest, and if, as so often happens, the films show a bone injury, he is already started in the proper path of healing.

Certain precautions in taking the x-rays are desirable. For careful comparison with the uninjured wrist, lateral views should be taken with the two wrists in the same position, and this can best be attained by putting the palms together with the fingers pointing forward in a "praying position." The posteroanterior views must always be taken in complete ulnar flexion, as in this position the long axis of the scaphoid is visible; and at

least two obliques are needed to complete the study, with the palmar and dorsal surfaces of the wrist alternately next to the plate. Not only should the most minimal fractures be searched for, but the surgeon must also be alert for any slight malposition of the fragments. As in other fractures, careful anatomic reduc-

Fig. 2—Axial view of the wrist taken in full dorsiflexion. This shows well the volar osseoponeurotic canal. The wire threaded through the tendon of the flexor pollicis longus is shown to be in intimate contact with the scaphoid.

tion is important, although in this injury it is frequently neglected because of the difficulties in interpreting the lateral films. Of certain clinical varieties of scaphoid fracture which may occur, an infrequent but easily treated type is an extra-articular fracture involving the tubercle. The most common injury is a fracture of the body, which may be linear or may show some displacement or angulation. Occasionally severely comminuted fractures are encountered; but these are more commonly associated with other carpal injuries. Fractures involving a small part of the proximal pole should be differentiated, because in this type the blood supply is poorest and the prognosis therefore is least favorable. The excellent work of Oblatz and Halbstern¹ on the blood supply of the carpal scaphoid showed that there was considerable variation in the distribution of the arterioles but that the majority of these were located distally and the fractures through the waist of the bone could interrupt the blood supply in about one third of the cases.

A large number of patients sustain this fracture by falling on the outstretched hand with the wrist in dorsiflexion. The force strikes the heel of the hand and is transmitted to the scaphoid, which may break over the radial styloid. But there is another mechanism of injury which may explain the close association of this injury with luxation of the semilunar. The scaphoid acts as a bone bridge across the junction of the proximal and distal carpal rows, so that any abnormal motion taking place between the semilunar and os magnum is checked by the scaphoid, and, as the force increases, the scaphoid must either break its body or tear the intra-articular ligaments attaching it to the semilunar, producing the not infrequent rotational shift without fracture.

This second mechanism is well illustrated by the so-called perilunar dislocation of the wrist with scaphoid fracture.

TREATMENT

In 1928 I reported a method of treatment of fractures of the carpal scaphoid which has now had ample trial, and its efficacy has been proved by a large number of reports by various workers.² Because at times certain phases of this method have been misinterpreted, and because certain slight improvements in technic have been acquired, it is believed that a detailed description of the present status of the method is indicated.

Treatment of each type of fracture must be individualized. Fracture of the tubercle offers little difficulty, since the bone in this area is covered by periosteum and is well vascularized. This is a rare lesion and usually of isolated occurrence. Full healing should take place in three to four weeks by simple immobilization of the wrist.

In treatment of fractures through the body, the first step should be to determine accurately whether any displacement is present. The lateral film should be carefully studied for angulation. In the presence of displacement, reduction can be obtained by traction on the thumb while the snuffbox is molded by the surgeon's fingers. Once alignment has been attained, the fragments can be impacted and properly immobilized by placing the wrist in full radial flexion with 20 to 30 degrees dorsiflexion and pressing the base of the thumb just below its proximal crease into full abduction. Technically it is preferable to perform this movement by placing the heel of the operator's hand on the same area of the patient's hand as demonstrated in figure 3. By this method full abduction of the thumb metacarpal is attained while the metacarpophalangeal and interphalangeal joints are allowed to remain in flexion, which is important because this position allows function to return more rapidly when immobilization is discon-

Fig. 3—Two views illustrating maneuver for manipulating the wrist into correct position of full radial flexion, 20 to 30 degrees dorsiflexion of the wrist with the base of the thumb in full abduction but its metacarpophalangeal and interphalangeal joints relaxed in slight flexion, the heel of the physician's hand pressing against the heel of the patient's hand.

tinued. It is imperative that ulnar flexion should be avoided, because in this position the scaphoid leaves its facet in the articular surface of the radius and moves

distally and radialward, the fractured surface tending to separate because the proximal fragment remains attached to the semilunar by the interosseous ligaments. On the other hand, in radial flexion the fragments closely approximate, especially when abduction of the thumb is added to this position. This can be readily

Fig. 4.—Arrow points to proper site of pressure and correct position of the hand, wrist and thumb.

demonstrated by producing experimental fractures in cadavers or by roentgenographic studies in the living.

In the anteroposterior plane, dorsiflexion at 30 to 40 degrees has been experimentally proved by Berlin³ to be an ideal position. Warning must be given about the use of too much dorsiflexion, because this may lead to anterior angulation of the fracture with eventual malunion.

Proper immobilization of the thumb is important for several reasons:

1. By its inclusion more complete fixation of the wrist can be attained.

2. Any active movement of the thumb involves the long flexor tendon and the abductor pollicis. The latter often originates in the tuberosity of the scaphoid, so that abduction of the digit produces motion in the distal fragment. The close relationship of the long flexor to the scaphoid can be shown by noting its anatomic position and by noting movements in experimentally produced fractures, when it can be shown that motion of the interphalangeal joint alters the relation of the fracture surface (figs. 1 and 2). Further confirmation can be obtained by asking the patient with recent fracture to flex actively the interphalangeal joint; this movement will produce severe pain.

3. Correct immobilization of the thumb avoids disability because, in application of the cast, care must be taken to force the thumb into abduction at its base rather than at its tip, since the latter procedure leads either to strain or to subluxation of the metacarpophalangeal joint. In this strained position recovery of function takes place much more slowly. The metacarpal, therefore, should be abducted, and the thumb should be relaxed in slight flexion (figs. 3 and 4).

TECHNIC OF PLASTER SPLINT

An anterior skin-tight plaster splint is first applied, and then one layer of circular flannel bandage is wrapped around the extremity. This is followed by a circular plaster splint. It is important that the plaster be carried as close to the elbow as possible and still allow full flexion of this joint, and, as previously mentioned, the plaster should extend to the middle of the thumb nail and to the metacarpophalangeal joint of the fingers. Mobilization of this area in scaphoid fractures will not produce the stiffness one always notes following Colles' fractures.

PERIOD OF IMMOBILIZATION

Early and rapid healing will take place in fractures of the tubercle of the scaphoid. In this infrequent extra-articular fracture, position of the wrist is not of consequence. On the other hand, fracture through the waist is the most common, and in this type correct and adequate immobilization is very important. Immobilization should be complete and undisturbed for at least nine to ten weeks; a large percentage of fractures will heal in this time, but four to five weeks longer may be necessary. Roentgenograms and clinical examinations should determine whether this further immobilization is

Fig. 5.—Method of holding hand while plaster is drying. Note that splint is carried to the metacarpophalangeal joints of the fingers and to the level of the middle of the thumb nail. No pressure is put on the tip of the thumb.

desirable. The presence of local tenderness in the anatomic snuffbox, or pain on percussion on the tip of the thumb, associated with inconclusive radiologic evidence of union, should warrant further immobilization. Sometimes the clinical evidence of union will appear before it is demonstrated in the x-ray.

³ Berlin, David. *New England J. Med.* 201: 574-579, 1929.

Certain authors have recommended prolonged immobilization, sometimes as long as twelve to eighteen months. I do not concur with this policy, because 95 per cent of cases will have united in four to five months and when union is delayed beyond that time there are certain complications which should be treated surgically rather than by further splinting. These are malposition of the fractures, interposition of strong fibrous bands, aseptic necrosis or an uncontrolled very small fracture of the proximal pole. In the latter injury, in which only the sixth or seventh body of the scaphoid is involved, an excision of the small fragment, if three months' splinting fails, results in better function than very prolonged immobilization.

When fractures of the scaphoid are associated with luxation of the semilunar, which occurs in about 12 per cent of the cases, the wrist must of necessity be held in slight volar flexion for the first four weeks. If it is placed in dorsiflexion in order to treat the scaphoid fracture, the semilunar may redislocate.

350 Post Street, San Francisco.

IATROGENIC HEART DISEASE

A COMMON CARDIAC NEUROSIS

ALFRED AUERBACK, M.D.

AND

P. A. GLIEBE, M.D.

SAN FRANCISCO

In a recent publication Gillespie¹ said "There is a chapter omitted from medical textbooks which might be headed 'Iatrogenic (Gr. iatros, doctor) Diseases'; that is to say, diseases produced by doctors. It is not well enough realized that it is dangerous to give a label to a set of symptoms of disease until you are convinced that it is the right one. If a syndrome is psychologically produced (which of course the patient does not know) and if the doctor also does not know this and calls it gastritis because the patient complains of indigestion, or a weak heart because he complains of breathlessness or precordial pain, or even if he attaches to it some cabalistic letters, such as D. A. H., then he has implanted a suggestion in the patient's mind which fixes his anxiety in a way which, if not quite indelible, is at any rate very hard to undo."

While the advance of clinical knowledge has definitely limited the scope of iatrogeny, it must be admitted that incorrect medical diagnoses are still far from uncommon. In our psychiatric experience we have seen patients whose symptoms had been incorrectly diagnosed by physicians as evidence of pathologic processes in nearly every bodily system. However, one system—the cardiovascular—has been predominant. In 1926 Viko² described cardiac neuroses initiated by physicians in cases of organic heart disease. In 1929 Kilgore³ described cardiac neuroses with no pathologic findings initiated by physicians. Oille⁴ has summed it up well by stating that almost 60 per cent of patients who consult a cardiac specialist are suffering from either an exaggerated or a wholly unnecessary anxiety about their hearts, arising from suggestion and not based on reason, most of the

suggestions following the careless or ill considered remarks of doctors.

From time immemorial the heart has been the traditional seat of the emotions and hence acts as the focal point of anxiety. The anxiety neurosis in its varying degrees, according to Weiss,⁵ is probably the most frequent disorder of civilized life. It has long been known that anxiety attacks produce disturbances of cardiac function such as palpitation, arrhythmia and tachycardia, also disturbances of respiration and other body systems, yet not always accompanied by recognizable anxiety. The presence of cardiac symptoms directs attention toward the heart. The psychic reaction to doubt concerning the integrity of the heart, Conner⁶ has said, seems to be much more violent and profound than is the case with any of the other internal organs. Most persons who would accept with considerable equanimity the knowledge that they had some disease of the liver or kidneys or lungs will have their morale sadly shaken by any evidence that the heart is not functioning properly. In the minds of most laymen the thought of heart disease is still associated with the idea of sudden and unforeseen death. We are reporting some cases from our records to show how errors of commission or omission by the physician have resulted in patients with varying degrees of incapacity and disability, owing to concern regarding their hearts. It is our hope that an awareness by the medical profession of this condition will lead to more careful management of predisposed individuals and great savings in time, money and mental anguish.

Conner has outlined the four groups of causes which may act as the precipitating events for the development of cardiac neurosis: (1) the statement of some physician or life insurance examiner that the heart shows *some abnormality*, (2) the occurrence of some dramatic case of heart disease (such as sudden death) among relatives or friends of the patient, (3) the appearance of symptoms calling attention to the heart, such as sudden pain or a skipped beat, and (4) some profound and protracted emotional disturbance, such as deep grief or prolonged anxiety. Oille has described these patients as sensitive or suggestible with a past or family history of nervous excitability. They usually have a pessimistic type of mind; that is, they take a serious view of their symptoms or what people tell them and are unable to forget or disregard unfavorable remarks as can optimistic persons. The majority of this anxiety group is made up of people who have a pain somewhere which they think is in their hearts or due to their hearts.

We are presenting a few cases from our series of cardiac neuroses to show how often the physician himself has had an important role in the initiation of the illness. For this reason we are confining ourselves to such cases and ignoring others in which family pressures or illnesses or other environmental influences have played the predominant role.

REPORT OF CASES

CASE 1.—A divorced woman aged 28 was referred for psychiatric study of her "heart attacks" after careful medical and laboratory examination had revealed no cardiac pathologic change. The "heart attacks" had begun at the age of 19 years and continued up to the time of study. They consisted of severe, constricting retrosternal pain passing up to the left

shoulder, palpitation, difficulty in breathing and numbness in both arms, more pronounced on the left. The attacks would last several minutes and occurred at rest or on exertion. The patient had seen many doctors, some of whom had diagnosed heart disease and had prescribed digitalis and other cardiac medications as well as vitamins and sedatives. Between attacks the patient was symptom free and able to lead a normal, vigorous life.

Psychiatric study revealed that the patient had been attached to her father until the age of 16. At this time, when she began to go out with boys, her father abruptly accused her of having syphilis and forced her to have a medical examination, which was negative. She was terribly upset by this experience and torn between love and resentment toward her father. She left home and, despite her father's entreaties, did not return to see him. Several years later her father died suddenly following a heart attack. This was a shock to the patient, accentuated by the death of her fiancé in a car accident a week later. It was following this she had her initial attacks of retrosternal pain, breathlessness and palpitation. The family doctor examining her thought that she might have "a leaking heart" and put her to bed. Hearing the doctor's words, the patient thought of her father's cardiac death and felt such would be her fate. Under emotional stress she had recurrent attacks, which several doctors diagnosed as "heart disease" even in the absence of objective findings. One thought her tonsils responsible and recommended their removal. In view of this, when several physicians told her that she had a "nervous heart" and "there was nothing wrong," she "felt they were crazy."

The patient married but had a great fear of sexual relations and pregnancy because a sister had died of postpartum infection. Since a "heart attack" would preclude sexual activity, she found this a useful device repeatedly. After five years of marriage with recurrent separations, she divorced her husband and came to California. She began to work and got along very well until she began an affair with a man, and her "attacks" recurred. The local doctor treated her for one year and finally referred her for further study.

The physical and electrocardiographic examinations were negative. Since the patient appeared tense and nervous, sighing frequently, she was overbreathed for one minute, reproducing in all details her "heart attack." The patient immediately recognized her symptoms and their method of production. After a series of psychiatric interviews, she married her friend and has remained symptom free since that time.

CASE 2.—A married woman aged 30 was referred for anxiety regarding her heart following the birth of a child. Physical examination and laboratory examination had shown no cardiac pathologic change. Reviewing her life history, it was found that at the age of 20, while undergoing a routine medical examination, she was told that she had "an enlarged heart." The doctor also recommended that she "tell her husband" when she married, which she interpreted to mean that she should not have children. From this time on she was troubled by palpitation and breathlessness, which one doctor told her was "pseudoangina."

She married and managed quite well, although there was constant discord between her husband and her mother, all living in the same home. When she became pregnant she worried excessively about her heart, and a physician, attempting to reassure her, jokingly said "We never worry about the heart during pregnancy but only after the baby is born." Consequently, immediately following the birth of the child she was troubled by the recurrence of her symptoms with accentuated intensity and a profound conviction that her heart would stop. Repeated medical examination and reassurance could not dissuade her.

Psychiatric discussions unearthed the sources of conflict with the mother and the husband. When she had gained insight regarding the home situation, the patient and husband moved away from the mother's home. The significance of her cardiac symptoms was explained; the interpersonal relationship between husband and wife clarified. She has continued well and free from anxiety since completion of the treatment.

CASE 3.—A man aged 25, complaining of attacks of precordial pain and shortness of breath for two years, was seen for psychiatric study. At the age of 12 years he had been told by his family physician that masturbation would lead to sexual debility and heart disease in later life. His "heart attacks" had begun two years previously at the time he became engaged. Despite repeated medical and laboratory examinations, he was convinced he had "heart disease." The attacks frequently came on at night while asleep, awakening him and forcing him to sit up and gasp for breath. With psychiatric study it was found that erotic dreams precipitated these attacks. Overbreathing for sixty seconds, the patient would produce an attack. When the mechanism of the attacks was explained and the original sexual fears due to masturbation were discussed, definite improvement ensued.

CASE 4.—A man aged 34, a butcher, was seen for complaints of pain over the heart and extreme nervousness. At the age of 19 his family doctor told him that he had "athlete's heart" and instructed him to "take it easy." However, repeated medical examination since that time had shown no pathologic condition. Psychiatric study showed that he had always been under the domination of an aggressive mother. To escape her he had married at 18 years of age to find that his wife had the same personality makeup as his mother. His feeling of being trapped and frustrated in this situation gave rise to anxiety symptoms, incorrectly diagnosed by the physician as being of cardiac origin. After finding out the factors underlying his symptoms, the patient decided that his marriage would never work. Since separation from his wife there has been a decided improvement in his condition.

COMMENT

Kilgore⁷ has stated that the physical signs often responsible for mistaken diagnoses of cardiovascular disease are benign murmurs and arrhythmias, simple tachycardia and temporary elevation of blood pressure from the excitement of a medical examination. The symptoms giving rise to error are those designated as neurocirculatory asthenia and effort syndrome. Summing it up, he feels that the disability of masquerade heart disease is almost always due to fear which usually comes from suggestion. The readiness of physicians to diagnose heart disease on the basis of an audible murmur is responsible for many cases of cardiac neurosis. He has said that a systolic murmur can be found in a considerable proportion of healthy young adults if they are examined in various postures, in different phases of respiration, before and after exercise. In the absence of supporting findings or history they should not be regarded as pathologic, the diagnosis of valvular disease being held in abeyance until radiographic and electrocardiographic studies have been made. Repeatedly, our patients have been told by their physicians that they had "a murmur" or "a leaking valve" or "a leaking heart" with no investigation beyond auscultation of the heart. Patient 1 was told that she had "a leaking heart" and when in later examinations some physicians told her that her heart was normal she "thought they were crazy."

Another error is that of some physicians who tell patients that they have "functional heart disease," "nervous heart" or "pseudoangina." As far as the patient is concerned, the physician is diagnosing a form of heart disease. If it was explained that the cardiac symptoms are due to nervousness but not due to any actual heart disease, such misunderstandings would not arise. Similarly, the use of diagnoses such as "athlete's heart" or "effort syndrome" imply to the patient that an actual disease entity is present.

7. Kilgore, E. S.: The Heart in Military Service, J. A. M. A. 117: 258 (July 26) 1941.

There is a tendency to recommend rest in bed as a general measure in patients exhibiting anxiety tension symptoms with resultant exaggeration and fixation of symptoms. In patients with anxiety about their heart the doctor's advice to rest in bed or "take it easy" confirms their worst fears. We have had many of these patients who as children or adolescents were ordered to bed following a "nervous breakdown." One patient, a woman aged 32, was told by her physician at the age of 14 years that rest was essential for the remainder of her life: "Never run when you can walk, never exert yourself unless it is necessary." The disastrous effects on the patient's subsequent life can be readily imagined and had nearly wrecked her marriage by the time she came under psychiatric care.

Next to preoccupation about the heart there is universal concern about blood pressure. The layman's ideas about blood pressure, accentuated by the impressive apparatus and technic, have given it an air of portentous meaning. Nearly every patient is anxious as to the results of this examination and places much importance on it. The glib use of the phrase "high blood pressure" or "low blood pressure" by the examining physician, without any careful explanation of its significance, may be the focal point of an anxiety state. It is indeed surprising to find the number of neurasthenic or depressed patients whose condition was ascribed to low blood pressure, if their blood pressure determinations tended to be in the lower ranges of normal variation. Similarly, many patients showing a slight elevation in pressure are told that their pressure is increased, even though the anxiety accompanying such examination is well known and might in itself be the cause of the elevation.

Even reliance on the electrocardiogram as a diagnostic aid may be a source of error. It has been shown that the anxiety tension states classed as the hyperventilation syndrome may show electrocardiographic changes which could lead the unsuspecting physician to diagnose heart disease.⁸ An awareness of the possible changes due to hyperventilation would obviate such a possibility. Recently a married woman aged 21 was seen in the outpatient department of the University of California Hospital complaining of precordial pain and breathlessness for which no organic pathologic condition could be found. An electrocardiographic record showed changes suggesting heart disease. However, the examining physician felt that a hyperventilation syndrome might account for the whole clinical picture. He was able to reproduce the entire symptomatology by the hyperventilation test. Psychiatric study revealed marital discord plus guilt feelings regarding a premarital sexual escapade. Fortunately he recognized the picture and so avoided the initiation of a cardiac neurosis.

At times the doctor, anxious to have a patient carry out his orders or submit to an operation, will unduly stress possible untoward effects if these measures are not followed through. While it is justifiable to mention that heart disease may be a possible consequence of neglected, diseased tonsils or sinuses or other toxic foci, it is unfair to imply that it is an invariable result of continued neglect. One patient was told, at the age of 15, that unless his "diseased tonsils" were removed he would be dead of heart disease in five years. He

is still alive and healthy at the age of 30, still with the same infected tonsils—but with a cardiac neurosis.

Again, the indiscriminate use of medications in the anxious patient all too often have a deleterious effect. Digitalis is made use of because the physician feels that in small doses it can do no harm and might do some good if, by chance, any slight heart disease should be present. Since most patients learn sooner or later that digitalis is a specific cardiac medication, they assume that they are being treated for heart disease. Frequently other cardiac drugs are used. At times the patient misconstrues his sedative mixtures as being specific cardiac drugs. In fact, the use of any medications or even placebos may lead to misconceptions unless their purpose is explained.

It cannot be too strongly emphasized that, since cardiac symptoms may occur in neuroses of all types and even in psychoses, they are only the presenting symptoms of a more fundamental disorder—the individual's inability to handle his personal and environmental problems. The physician, limiting his attention to the cardiac symptoms, permits the major personality disorder to escape unnoticed and helps to fix the anxiety at a somatic level.

While anxiety cases showing cardiac symptoms are less frequent in the present struggle compared to World War I, they still are common and present a major problem. In his Goulstonian Lectures on the effort syndrome Wood⁹ pointed out that a number of the cases in his series had been induced by the doctor. The accidental finding of a systolic murmur or of tachycardia was usually the source of error. Evidence of predisposition was common. Given the suggestible subject, the doctor often succeeded in linking emotional reactions to effort by grafting on the mind of the patient the idea that his heart would not stand up to exertion. Douglas-Wilson¹⁰ found cardiac symptoms the most common somatic manifestations in a group of psychoneurotic soldiers. The induction of symptoms by suggestion through prolonged confinement to bed or by doctors' or relatives' warnings was found in 14 of the group of 53 cases. It was noted that, whatever the reason for the patient's having been confined to bed—it varied from head injury to "nervous breakdown"—the patient himself had supposed that it was because of "something wrong with the heart." Not one of the patients that had been instructed to "take things easy" had sought further advice after the initial warning.

In addition to these cases recognized as cardiac manifestations of a psychogenic disorder there are countless numbers incorrectly diagnosed. Lewis,¹¹ in reviewing the studies at Hampstead from 1914 to 1918, estimated that about five sixths of the British army diagnoses of organic heart disease were erroneous. Commenting on this, Kilgore stated that in the United States services many diagnoses of mitral insufficiency, myocarditis, angina pectoris and the like were mistakenly entered in the records and carried forward as grounds for disability ratings long after the passage of years and accumulating evidence should have removed any doubt of the original diagnostic errors. Considering the great number of men incorrectly labeled as suffering from "heart disease," the extent of the iatrogenic illness so created is indeed appalling. One wonders if the same diagnostic errors are recurring in the present conflict.

While only after postwar surveys will the answer be known, the impression is that we do not yet recognize psychogenic disorders of this type.

One of us, while serving as psychiatrist at an army induction center, was surprised to find a rather considerable number of healthy young men concerned about their having heart disease, despite the absence of any clinical findings. Repeatedly they stressed the fact that the family doctor had diagnosed heart disease and were surprised, if not actually irked, when told that their cardiac examinations were negative. While those exhibiting anxiety tension states were rejected, the great majority of these men were deemed acceptable for military service. It will be interesting to ascertain some day their later reactions to the strains of military life and service.

TREATMENT

It has been reported by many observers that the majority of patients coming to the doctor with cardiac symptoms do not have heart disease.¹² However they have anxiety about their hearts and, as a fertile field for cardiac neuroses, must be handled carefully. The physician's primary task is to reassure the patient not only through his words but through his attitude. A careful history and thorough physical examination, with laboratory aid where indicated, impresses the patient with the physician's interest and permits an acceptance of his diagnosis. Statements the doctor makes should be positive and definite and, if he is in doubt about certain points, it is best not to mention these. If heart disease is found, the doctor should frankly state the case and advise accordingly, being careful not to implant an exaggerated idea of the gravity of the condition. If he is sure the signs and symptoms do not mean heart disease, he must be equally frank and decided. When he feels the need for roentgen ray or electrocardiographic study, he must explain why and answer any questions whether expressed or not. More important than words is his attitude, since any semblance of uncertainty may nullify his reassurances. Having another doctor listen to an interesting though benign murmur or a suggestion for increased rest or even a vague recommendation to "take it easy" implies some positive finding to these suggestible individuals. When the symptoms are associated with anxiety, the doctor should briefly explain the physiologic and psychologic mechanisms responsible, so that the patient can understand the basis of his otherwise incomprehensible symptoms. To send a patient on his way with the statement that "nerves" are responsible for his difficulties is to leave him prey to many worries and unwholesome thoughts. A few simple sentences by the doctor may save months and years of anguish.

We have previously reported an overbreathing test that in many cases can reproduce the cardiac symptoms complained of by an emotionally disturbed individual.¹³ The patient, while seated relaxed in a chair or comfortably lying down, is instructed to breathe deeply in and out through the mouth. He is usually asked to sigh once or twice and then told to do so very deeply at regular intervals, forcing all the supplemental air from the lungs. This is continued at a rate of 15 to 25 respirations per minute for a period of one to three minutes. To insure deep respiration with complete removal of the air and to regulate the rhythm

the physician presses lightly on the lower sternum or epigastrium. In many patients this is not necessary, since the patient overbreathes satisfactorily without intervention by the doctor. The time interval from the beginning of the test to the onset of symptoms is noted. In most cases symptoms will be definitely present within sixty seconds and should be pronounced within a minute or two. If symptoms are not present after a three minute period, the test should be discontinued, provided that during the three minutes the ventilation was trebled or quadrupled. The physician must be sure that there is adequate respiratory exchange, since some patients go through the motions of deep breathing, raising and lowering their shoulders, without actually overbreathing. Rarely has it been necessary to continue the hyperventilation for fully three minutes, since the patient will request that the test be discontinued after one or two minutes, often stopping of his own accord. At this point the patient may recognize that these symptoms are those of which he has originally complained, otherwise this fact should be brought to his attention. He is told that his symptoms are not those of a physical disease but are due to emotional problems whose undischarged emotional tension causes him to sigh or overbreathe. It is explained that sighing, yawning, panting, "catching one's breath" or any other form of deep breathing all represent the same process and have the same result in their production of these symptoms of overbreathing.

In the absence of psychiatric treatment designed to uncover the psychologic mechanisms responsible, most patients will continue to have symptoms. Therefore it is important for the physician to urge the patient to live a normal life in spite of his symptoms. He is urged to return to work and to assume his regular duties, perhaps doing lighter work at first but gradually doing more with increasing improvement. A great deal of pressure by the doctor may be necessary to initiate the first steps, such as going upstairs, walking down the street or going downtown despite the presence of symptoms. It is permissible to use mild sedatives, but it must be made clear to the patient that they are given for his nervousness and not for his heart. Rest should not be prescribed unless absolutely necessary, but increasing activity should be the rule. It is questionable whether eliminating coffee and tobacco does much good. Frequently the doctor may have an idea as to the sources of psychologic upset. Adjusting marital difficulties, particularly in the sexual sphere, or recommending business or environmental changes may effect a decided improvement. Probably many patients can be handled at such a superficial level. Where the difficulties are more deep seated and do not respond to these measures, psychiatric consultation should be sought.

CONCLUSION

In emotionally disturbed individuals, cardiac disturbances are commonly the presenting symptoms of their anxiety. Often careless or ill timed remarks of the physician may initiate a cardiac neurosis. Every patient consulting a doctor for anxiety tension states, particularly those with cardiac symptoms, must be considered as potentially having a cardiac neurosis and managed accordingly. When careful physical and laboratory examinations reveal no organic findings, the patient must be told so unequivocally. Some of the sources of error in diagnosis and management have been mentioned. Recognition by the physician of the presence of underlying personality disorders in such cases will help reduce the incidence of iatrogenic disease.

DEATH FROM AIR EMBOLISM FOLLOWING INSUFFLATION DURING PREGNANCY

REPORT OF A CASE

HERBERT S. BREYFOGLE, M.D.
ST. LOUIS

Insufflation has been a medical practice since early in the nineteenth century. The earliest recorded mention of it appeared in 1823. There are descriptions of its use for therapeutic and diagnostic purposes in connection with almost every opening and cavity of the body. Despite the fact that it has been used widely and frequently since then, insufflation has not been regarded as a dangerous procedure.¹

The first reference in medical literature to insufflation of the vagina with silver picrate as an effective treatment of trichomoniasis appeared in 1936.² Since that time three deaths directly attributed to insufflation of the vagina during pregnancy have been reported, one from Canada³ and two from England.⁴ Attention was directed by these accounts to the dangers of the method; especially when applied during the latter part of pregnancy. One author referred to the fact that the English manufacturer of the drug "Picrotol" warns the physician against its use in these circumstances.⁵

The following death from air embolism resulting from insufflation during pregnancy is therefore the fourth from this means to be reported, and the first to be recorded in the medical literature of this country.

REPORT OF CASE

A white woman aged 21 was brought by ambulance to the St. Louis County Hospital from the office of an osteopath on Aug. 14, 1944 and pronounced dead on arrival. An inquest held by the county coroner disclosed the following facts: The decedent, a housewife and trigravida, had consulted the osteopath on August 14 at 9 p. m. because of an irritating vaginal discharge. She was admitted to the treatment room at about 9:15. Shortly thereafter the osteopath began to insufflate the vagina with silver picrate compound powder 1 per cent silver picrate in kaolin,⁶ Wyeth, using a Shelanski insufflator⁷ (Wyeth) fitted with a soft rubber vaginal shield. It was estimated that from one half to two thirds of the standard container (Wyeth) attached to the insufflator was filled with silver picrate powder (2 to 3 Gm.) when the treatment began. The patient was supine, with her feet elevated in stirrups, during the proceedings.

Approximately five minutes after the conclusion of the insufflation the patient sat up and asked a question. In a

moment she became noticeably pale and said "I feel sick" and fell back on the examining table, suddenly inhaled deeply and emitted a peculiar sound as if she was strangling. Shortly thereafter she was dyspneic, cyanotic and unconscious, and a white froth began to exude from the mouth. The respirations were irregular and then ceased. External stimulants, epinephrine by hypodermic injection and artificial respiration were administered, but within a period of from twenty to thirty minutes after the initial symptoms appeared no heart beat could be detected. Death was recorded officially as having occurred at 10:20 p. m.

Testimony by two members of the immediate family of the decedent did not provide any relevant information with particular regard to heart disease, syncope, injury or convulsions. There was some evidence that the decedent had suffered for several days previous to her death from cramps in the region of the lower abdomen, weakness and "dizzy spells." The records of the osteopath indicated that the patient had visited him on three previous occasions since June 1944 in connection with her pregnancy, which was expected to terminate in October 1944. On June 28 the patient complained of an irritating vaginal discharge for the first time during the pregnancy and was treated with silver picrate powder administered by insufflation in the same manner as on the day of death. A normal blood pressure was obtained on two occasions (110/55) with a pulse rate of 100. On June 10 the temperature was 100 F. and on June 28 99.6 F. The osteopath stated that on July 10 he observed no change in the condition of the patient. She was advised to use vaginal suppositories containing silver picrate (Wyeth) until she returned to his office in August. The decedent had been delivered of a seven months pregnancy in July 1943 by the same osteopath. The child died within twenty-four hours. A Kahn test performed by the St. Louis County Health Department Laboratories in July 1943 was reported as negative. The decedent was the mother of one living child.

The autopsy was performed eleven hours post mortem. The body had been placed in a standard morgue refrigerator (temperature 5 C.) shortly after death was pronounced officially. The diagnoses were the following: Primary: Gas bubbles in the right auricle and ventricle of the heart; edema and congestion of the lungs; hemorrhagic infarct of the lower lobe of the left lung; pregnant uterus containing a normally implanted placenta and a fetus weighing 1,625 Gm. and measuring 430 mm. (crown to heel); discoloration (brown-black) of the vaginal mucosa; subpleural petechiae. Accessory: infarct of the right kidney; adrenal rests of the kidneys; polyp of the ascending colon.

The heart was immersed in water in situ before being incised. The blood within the right auricle and ventricle was noted to be frothy, but this was not observed elsewhere. The placenta was implanted on the left posterolateral surface of the uterus. There was no evidence of hemorrhage or separation. The membranes were intact. The fetus was in an attitude of flexion with the head presenting. Bacteriologic examination of blood removed from the heart showed colon bacilli. No organisms of the Clostridium group were reported.

COMMENT

The clinical picture in this case—pallor, dyspnea, cyanosis and sudden collapse—strongly suggested an acute fulminating anoxia. There was evidence of an initial stimulation of respiration, which then became labored, irregular and finally ceased within a brief period of time. The appearance of a frothy exudate in the mouth reflected the rapidly developing respiratory difficulty. The association of cyanosis with these changes was consistent with acute anoxia. No information could be provided in regard to the blood pressure changes necessary to complete the clinical manifestations of acute fulminating anoxia. Lacking also was a history of sudden, excruciating retrosternal pain so often recorded in cases of postoperative pulmonary embolism. The character of the postmortem observations tended to

remove from serious consideration a diagnosis of primary reflex circulatory failure independent of all other causes as suggested by the reports of Weiss, Capps and others.⁸

Mechanism.—Although the exact port of entry was not demonstrated⁹ at autopsy it may be supposed on the basis of the postmortem observations that air entered the systemic venous circulation at the site of placental implantation and was carried directly to the right auricle and ventricle of the heart. If the quantity of air thus reaching the heart was small, or if it was introduced at a slow rate, the resulting delay in the pulmonary circulation would be of no consequence. But in a case in which a large volume of air gained entrance to the systemic circulation, as in this instance, the time interval of interruption of the blood flow through the pulmonary artery would have been sufficient to bring about collapse and probably death.¹⁰ According to several investigators,¹¹ 8 cc. of air per kilogram of body weight can be fatal if injected intravenously in dogs within twenty to thirty seconds. Richardson and his co-workers found that in dogs large volumes of air injected intravenously at a rate of 0.12 cc. per kilogram of body weight were tolerated well. One animal received 1,377 cc. of air in this manner in four hundred and sixty minutes without serious consequences. They noted, however, that 100 cc. of air introduced into the venous system within twenty to thirty seconds in a dog weighing 12 Kg. was fatal. Wolffe and Robertson,¹² on the other hand, claimed that intravenous injection of amounts less than 15 cc. per kilogram in dogs was not fatal. Karsner¹⁰ reported that 450 cc. of air proved fatal within twenty-five minutes to a dog weighing 10 Kg. when the air was introduced intravenously in amounts of 20, 30, 50 and 70 cc. at a time.

The conclusion reached by many authors¹³ discussing air embolism is that death results from mechanical obstruction of the pulmonary artery.

Physical Factors.—The physical factors involved in death from air embolism following insufflation of the vagina do not lend themselves readily to duplication in the laboratory. The apparatus employed is at best a crude implement serving merely to direct the drug or chemical where it is most useful; individual variations are introduced by the physician according to the manner in which he uses the device. Other modifications can appear, depending on defects in the instrument resulting either in manufacture or from long continued use. In order for pulmonary air embolism to occur, however, it is known that (1) there must be a positive pressure at the point where the gas enters the vein and (2) approx-

imately 500 cc. of gas must enter the vein within a relatively short time.

It is recommended generally in cases in which the use of silver picrate by insufflation is indicated that 5 Gm. of 1 per cent silver picrate in kaolin be administered.² A Shelanski insufflator (Wyeth) was obtained and fitted with a standard glass vial (Wyeth) into which from 1 to 5 Gm. of the powder was placed. The insufflator was attached then to a graduated and stoppered flask filled with water and so arranged that compression of the rubber bulb of the instrument would displace a measurable amount of fluid from the container. When all of the powder had been ejected from the vial attached to the insufflator, readings were taken of the total liquid displaced from the water flask. Three separate trials were made using this method. The results are shown in the accompanying table.

From these results it would appear reasonable to assume that, if the conditions during the insufflation of the patient (when 2 to 3 Gm. of the powder was administered) were in any way comparable to those of the foregoing experiment, an amount of air between approximately 925 and 2,200 cc. was injected into the vaginal cavity within a period of several minutes. The capacity of the vagina is, of course, a matter that can only be estimated. If it is presumed that in the case of the average woman the vagina is a cylinder measuring

Amount of Water Displaced by Air Ejected from the Shelanski Insufflator When Varying Quantities of Silver Picrate Are Employed

Amount of Silver Picrate, Gm.	Cubic Centimeters of Water Displaced		
	I	II	III
1	425	625	450
2	1,025	1,125	925
3	1,225	1,325	1,300
4	1,850	1,950	2,200
5	2,700	2,800	3,000

approximately 8 cm. in height and 5 cm. in diameter, then its capacity is obtained from the formula $\pi r^2 h$ and thus computed to be 157 cc. This consequently might be regarded as the minimum capacity. The maximum volume of the vagina in the average woman must be based on the alteration of its dimensions during parturition. The greatest diameter to which the vagina might expand during labor is 13.5 cm. (the occipitomenstrual diameter of the fetal head). According to the formula $\pi r^2 h$, therefore, the potential capacity of the vagina may be considered as at least 1,144 cc. It is unlikely that any patient would submit to a treatment which would suddenly distend the vagina to its limit, even if it was possible to do so. Moreover, should the rubber vaginal shield with which the instrument is equipped be pressed firmly enough against the perineum to prevent the escape of air to the outside, any positive pressure created within the vagina should tend to force the gas into the uterus. If the foregoing figures are valid, then in this case a positive pressure was created within the vagina which forced at least 500 cc. or more of air into the pregnant uterus within a brief interval of time, thus providing the necessary requisites for air embolism to result.

CONCLUSION

The facts brought forth by studies of deaths resulting from vaginal insufflation during pregnancy indicate that it can be an extremely dangerous procedure, especially in the latter half of gestation. In 3 of the cases, including the 1 reported here, the decedents were nearing

8. Weiss, S., and Baker, J. P.: Carotid Sinus Reflex in Health and Disease: Its Role in Cautation of Fainting and Convulsions, *Medicine* 12: 297, 1933. Capps, J. A.: Air Embolism versus Pleural Reflex as Cause of Pleural Shock, *J. A. M. A.* 109: 852 (Sept. 11) 1937.

9. As Moritz points out, it may prove difficult to show the specific site of entry of air into the endometrium (Moritz, A. R.: *Pathology of Trauma*, Philadelphia, Lea & Febiger, 1942, p. 133).

10. Karsner states that the foam which forms when air is mixed with circulating blood can require 50 per cent more time to pass through capillaries than blood alone. An additional delay may be thought to occur at the same time within the right ventricle. As a result, following systole there is probably a considerable residue of foamy blood within the right ventricle (Karsner, H. T.: *Human Pathology*, ed. 6, Philadelphia, J. B. Lippincott Company, 1938, p. 119). According to Bard, a rapidly induced anoxia (as in the case of inhalation of inert gas) results in unconsciousness and collapse within forty five to eighty seconds (Bard P.: *MacLeod's Physiology in Modern Medicine*, ed. 8, St. Louis, C. V. Mosby Company, 1938, p. 374).

parturition, and of these 2 were multiparous. The fourth death, although it occurred in only the fourth month of pregnancy, also involved a multiparous mother. It would seem, therefore, that multiparity as well as the terminal stage of gestation is a factor adding to the risk of such insufflation. In view of the fact that other methods are equally effective in the treatment of trichomoniasis it appears that insufflation of the vagina may be abandoned. As long as this method is used, however, a warning should accompany the sale of the drug and the device.¹⁴

Clinical Notes, Suggestions and New Instruments

A TRANSFUSION REACTION DUE TO A DANGEROUS UNIVERSAL DONOR

FAILURE OF THE SECRETING FACTOR TO PROTECT THE RECIPIENT

SAUL MALKIEL, M.D., PH.D., AND WILLIAM C. BOYD, PH.D.
BOSTON

Since some controversy still exists as to whether a group O donor with an unusually high titer of isoagglutinins can be dangerous when his blood is transfused into a recipient of one of the other three groups, we report here a case in which the evidence seems particularly convincing that such "universal donors" can really be dangerous.

A girl of 19 who had never been pregnant, belonging to blood group A, received 450 cc. of citrated whole blood of group O. No untoward signs were noticed during the transfusion, but forty-five minutes after completion of the transfusion the patient complained of a feeling of oppression and had a severe chill. The temperature rose somewhat over 102 F. Jaundice developed, and the icterus index had risen to 62 units within eighteen hours after the transfusion. During the next twenty-four hour period oliguria developed. The patient voided only 85 cc. of urine during this period, and the urine contained large amounts of urobilinogen. The nonprotein nitrogen of the blood was found to be 100 mg. per hundred cubic centimeters at the end of the twenty-four hour period. Recovery was slow, but at the end of several weeks the patient seemed to have recovered completely from the effects of the transfusion.

Because of evidence suggesting that the reaction might be due to the use of group O blood, a sample of blood from the patient was examined, thirty-six hours after the transfusion, to see whether the hemolysis had affected the patient's or the donor's cells. The method of Ashby was used.¹ This has the advantage of requiring very little blood and gives results of sufficient accuracy in most cases.

It was found that the total red blood cell count of the patient at this time was 3,350,000, a figure which may be accurate to about 1 per cent. By making the dilutions with a strong anti-A serum, prepared by the method of Witebsky, Klendshoj and McNeil² and counting the unagglutinated cells, it was found that the group O red cell count was about 350,000. Since the patient weighed 59 Kg., we may estimate that she had originally about 4.7 Kg. of blood, or possibly somewhat less. Assuming 400 cc. of whole blood to have been present in the 450 cc. of citrated blood which was administered, this means that the introduced blood amounted to about 8.5 per cent of the recipient's total, leading one to expect a count of group O cells initially of about 380,000. The figure actually found does not seriously differ from this, considering the uncertainties involved. It is of importance to note, however, that the patient had a total red count of 4,250,000 before the transfusion, which shows

that she had lost 4,250,000—(3,350,000—350,000), or 1,250,000 red cells per cubic millimeter. This amounts to about 29 per cent of the patient's own cells.

It seems clear that the destruction has been almost entirely of the patient's and not the donor's cells. The amount is large enough to be quite serious and amply sufficient to explain the symptoms observed.

The serum of the donor was titrated to determine the strength of the isoagglutinins present, and an anti-A titer of between 1:1,024 and 1:2,048 was found. The anti-B titer, though less, was still high, namely 1:512. It is clear that this donor has an unusually high titer, for we find, by our technic,³ an anti-A titer of around 1:64 in the average group O serum.

It has been suggested by some that the secreting factor⁴ which determines whether or not water soluble blood group substance will be present in the tissues and secretions of the individual may assist, when present, to prevent transfusion reactions due to incompatible agglutinins of the donor. It might be expected that a large part of the introduced agglutinins would quickly be neutralized by the group substance present in the plasma and tissues of an individual of the secreting type, thus protecting his erythrocytes from their action. However, when we examined samples of saliva from the patient⁵ we found to our surprise that the patient was a "secretor,"⁶ and that group A substance was present in her saliva in considerable amount and therefore, by inference, in her plasma and tissues.

SUMMARY

A case of transfusion reaction due to the use of a dangerous (high titered) universal donor was observed in which the recipient lost nearly 30 per cent of her original red cells as a result of the transfusion but ultimately recovered. It was found that although the patient, who belonged to group A, was a "secretor," nevertheless the group substance present in the plasma and tissues obviously had not served fully to protect the patient's erythrocytes against the action of the incompatible isoantibodies. It is not known whether the reaction might have been more severe if the patient had been a nonsecretor.

SCHISTOSOMA HEMATOBIUM INFECTION

SEWARD E. MILLER, BALTIMORE

Surgeon, U. S. Public Health Service, U. S. Marine Hospital

Vesical schistosomiasis has been exceedingly rare in this country and seen exclusively among patients of foreign extraction or natives who have been traveling or residing abroad. There is no endemic focus of vesical schistosomiasis on the North American continent. In the North Central states and neighboring regions of southern Canada there is an endemic focus of schistosome dermatitis or "swimmers' itch,"¹ but this parasite appears incapable of maturing in man. Large numbers of our armed forces have been engaged in actual combat in North Africa, fighting in fields and through streams where *Schistosoma hematobium* is endemic. With the return of these men we may expect that some will be infected. If the infection is light, symptoms may not appear for a matter of years, and so it is quite probable that men infected abroad may not have symptoms until some time after their return to civilian life. Therefore I feel it is highly desirable to report such a case in detail.

G. S. K., a white man aged 27, Egyptian, was admitted to the U. S. Marine Hospital, Baltimore, on June 7, 1944 complaining of blood in his urine for the previous four months. Late in February 1944 he had developed frequency with nocturia of four to seven times and associated lower abdominal cramps. Almost persistently at the termination of urination he had noticed a few drops of blood. There was also moderate burning on urination, and for the two months previous to his hospitalization he had had occasional sharp pains in the peri-

14. Since this article was submitted for publication an additional death from air embolism following insufflation during pregnancy has been reported (Martland, H. S.: Air Embolism: Fatal Air Embolism Due to Powder Insufflators Used in Gynecologic Treatments, *Am. J. Surg.* 130: 164 [May] 1945).

nium during urination. He had also experienced a few vague episodes of chills and fever between February and June. There had been no loss of weight. A review of his systems showed no other symptoms. The patient considered himself to be in good health aside from the symptoms enumerated. The pertinent facts in his past history revealed that he was born in the Nile Delta in Egypt, where he lived in a rural community and frequently played, waded and swam in irrigation ditches and tributaries of the Nile Delta. None of his family to his knowledge had developed any similar difficulties. He left Egypt over three years previous to admission, he served as a seaman aboard a British ship engaged continuously in the North Atlantic service, and he had not returned to Egypt since starting his service as a seaman. In fact, he was ashore but little even in the North Atlantic ports. He stated that he had been perfectly well until February.

Physical examination showed that he was well developed, slightly obese and not acutely ill. The temperature, pulse and respirations were normal. Significant clinical findings were a thin pannus along the upper margins of both corneas, some scarring and granulations in the conjunctiva of both upper eyelids (old inactive trachoma) and mild tenderness on deep pressure over the urinary bladder. The external genitalia and the rectal examination were normal.

Cystoscopy showed on the midposterior wall of the bladder two closely approximated, rounded, reddish, edematous masses, each about 1 cm. in diameter, which were elevated 3 to 4 mm. above the surface. The mucosa covering these nodules was vascular and rather piled up in small, "raspberry-like" groups. Arranged about these two lesions was a series of small, satellite, cystic nodules, each about 2 mm. in diameter, having thin walls and containing a thin, yellowish white fluid. Sections of the biopsy specimen showed an intact epithelium with a very

Urine examinations of the terminal bloody urine revealed many typical ova of *Schistosoma hematobium*. Stool examinations showed no ova or parasites. The patient's blood count was normal, with only 3 per cent eosinophilia. His blood urea nitrogen was 11.0 mg. per hundred cubic centimeters and the serologic examination was negative.

Fig. 2.—Higher magnification of single ovum showing internal structure; $\times 200$.

Fig. 1.—Section from biopsy of bladder lesion showing a deeply placed single ovum surrounded by dense granulation tissue; $\times 80$.

granulomatous mass beneath, diffusely infiltrated with lymphocytes, plasma cells and many eosinophils. In the midst of this there were two small clusters of cross cut and tangentially cut ova. In one section one of these ova was cut centrally and perfectly longitudinally. This longitudinally cut ovum showed a sharp terminal spine on its pointed end. The diagnosis was *Schistosoma hematobium* infection of the urinary bladder.

The patient was placed on a high fluid intake with a regular diet, and intramuscular injections of fuadin every other day were started. The initial dose was 1.5 cc., followed by a second dose of 3.5 cc., and then each succeeding dose was 5 cc. until a total of 40 cc. had been administered. The urine became free from ova in the latter part of June and remained free. The hematuria and all symptoms disappeared shortly after treatment started, and there was no reaction to the fuadin. On July 4 cystoscopy revealed definite improvement, with very slight evidence remaining of the previous polypoid-like lesions. A biopsy showed only granulation tissue beneath the mucosa, with a diffuse cellular infiltration of lymphocytes and eosinophils. No ova were found.

COMMENT

Prompt diagnosis is very important, because therapy by antimony compounds gives best results in recent rather than in long standing infections in which extensive tissue damage has taken place. In late cases after pronounced scarring, deformity and sinus tracts have formed, therapy is of little avail and the prognosis is poor. Even in the early cases more than one course of the drug may have to be given. Antimony and potassium tartrate and sodium antimony tartrate are given intravenously, while fuadin (stibophen) is given intramuscularly. These drugs kill both the adult worms and the ova. Fuadin appears to be the least toxic and to cause few reactions. It gave excellent results in our case. Liver involvement is infrequent in *Schistosoma hematobium* infections but does occur when the infection is heavy and the case is untreated. Local carcinomatous changes in the polypoid growths in the bladder have been reported fairly frequently in long standing untreated cases.

During the four months before coming to us this patient had been hospitalized on two occasions at other institutions. Cystoscopy was done both times, and the first time the impression

was that of benign polyps. On the second occasion the impression was that of a papillary carcinoma and he was transferred to the Tumor Clinic at the Marine Hospital, Baltimore, for treatment. At neither of these cystoscopies was a biopsy taken. The patient's terminal urine was not examined microscopically.

Human schistosomiasis is a rare entity in this country, and our literature contains but few references to this disease. Only one of these² refers specifically to *Schistosoma hematobium* infection. However, the textbooks³ on tropical diseases contain excellent discussions, for *Schistosoma hematobium* infection has been extensively studied in Egypt and North Africa. The reader is referred to these textbooks for details of the life cycle, pathology and epidemiology. It is sufficient here to summarize the salient features. Man is the principal definitive host. Only a few monkeys have been found naturally infected. The ova are passed in the urine and rapidly hatch (in warm weather), liberating a free swimming parasite, the miracidium, which seeks the suitable intermediate host, a snail. Within the snail metamorphosis occurs with the development and liberation of large numbers of cercariae, minute fork tailed parasites which swim about, searching for their definitive host, man. They penetrate the unbroken skin, lose their tails and enter the circulation. They lodge in the portal radicles, feed, develop and become sexually differentiated in about four to six weeks. The young parasites emerge from the liver and work their way down into the veins of the urinary bladder. In severe and heavy infections some of the parasites lodge in the hemorrhoidal

We have in this country snails related to those that serve as the intermediate host in Egypt and Africa. However, it has not been proved that these snails will serve as suitable intermediate hosts. Because of the difference in our living and working conditions it is extremely doubtful that any focus of *Schistosoma hematobium* is likely to be established by the scat-

Fig. 4.—Centrally cut ovum, showing the characteristic terminal spine; $\times 300$.

tered cases of *Schistosoma hematobium* infection returned from abroad.

In our case we found large numbers of ova in the terminal urine, and, indeed, many ova frequently hatched while on the microscope slide under observation without any dilution of the urine. Generally it is recorded that a dilution of urine with 10 parts of water is necessary for these ova to hatch. All our efforts to preserve these ova with the usual chemical preservatives, such as solution of formaldehyde and glycerin, were failures, for within thirty-six hours no intact ova could be found, and we came to the conclusion that no known chemical preservative was satisfactory. The ova hatched rapidly if warm but more slowly if cool. From this experience we feel that rapid freezing might be a possible satisfactory method of preserving these ova. If a specimen is to be shipped and preservation of the ova is desired, rapid freezing and subsequent packing in solidified carbon dioxide offers a possibility of preservation and shipment.

Fig. 5.—Centrally cut ovum, showing the characteristic terminal spine; slightly reduced from a photomicrograph with a magnification of 600 diameters.

CONCLUSIONS

1. Symptoms of *Schistosoma hematobium* infection may not develop for many months to several years after exposure if the infection is light.
2. Biopsies should be taken of polypoid bladder lesions seen on cystoscopy.

Fig. 3.—Nest of ova immediately beneath intact bladder epithelium; slightly reduced from a photomicrograph with a magnification of 160 diameters.

and rectal veins. The fertilized female then deposits her eggs in rows in the walls of the fine tributaries of the vesical veins. The shell is rather porous, and the ova probably secrete a lytic enzyme which aids in their erosion through the vessel wall and bladder mucosa. This process is irritating and there is considerable cellular infiltration characterized by large numbers of eosinophils and also much fibroblastic proliferation. Some ova are permanently walled off and calcified, but many others pass into the urine, causing eroded and ulcerated areas. At the end of urination muscular contraction is strongest and results in bleeding and liberation of many ova from these polypoid and ulcerated lesions in the bladder.

In heavy infections symptoms occur and ova may make their appearance in the urine within sixty days after infection. However, many months may elapse before symptoms occur and ova are present in the urine. In our case at least three years elapsed between infection and the appearance of symptoms.

2. Blum, B. B., and Lidga, H. V.: *Schistosomiasis Infection: Report of Two Cases Found in Northern Michigan*, J. A. M. A. 121: 125-126 (Jan. 9) 1943.

 6. Bercovitz, Z. T.: *Clinical Tropical Medicine*, New York, Paul B. Hoeber, Inc., 1944.

3. Persons developing hematuria who give a history of having been in Egypt or North Africa should have microscopic studies of their terminal urine for *Schistosoma hematobium* ova.

4. Fuadin is an effective drug in the treatment of *Schistosoma hematobium* infections.

5. Ova of *Schistosoma hematobium* hatch rapidly when warm, even without dilution of the urine with water.

6. No known chemical means of preserving these ova has proved satisfactory.

7. Rapid freezing is suggested as a possible method of preserving these ova.

8. In the light of our present knowledge, endemic foci in this country of *Schistosoma hematobium* are not to be anticipated.

THE DANGER OF INTRAMUSCULAR INJECTION OF CALCIUM GLUCONATE IN INFANCY

REPORT OF THREE CASES, WITH ONE DEATH

STANLEY S. LAMM, M.D., BROOKLYN

My purpose in this paper is to stress and reemphasize the danger of using calcium gluconate for intramuscular injection in infants.

In 1936 there were two reports which recorded the effects of calcium deposition in the tissues of 2 infants who had received the calcium intramuscularly. Tumpeer's case¹ was that of an infant who weighed 6 pounds 13 ounces (3.1 Kg.) and received 9 cc. of 10 per cent calcium gluconate intramuscularly on the third day of life. At the age of 5 weeks x-ray examination demonstrated a radiopaque substance in the thigh and buttocks where the injection had been made. A week later there was a slough of the tissue, with the extrusion of calcified material which was identified as calcium phosphate. By the fourth month of life an x-ray of the region was normal. Von Hofe² reported the case of an infant who had received calcium gluconate intramuscularly because of twitching on the third, fifth and sixth days of its life. Ten cc. of calcium gluconate had been injected into the gluteal muscles on two occasions, and one dose of 10 cc. had been given intramuscularly. All the areas became indurated at the age of 2 weeks and infection occurred in one of the regions previously injected. X-ray showed calcification in the soft tissues of the gluteal and the scapular regions. Bakwin³ and Shannon⁴ have reported other instances of infection following intramuscular injections of calcium gluconate.

I now report 3 cases of infants who received calcium gluconate intramuscularly with subsequent abscess formation. In the last one gangrene of the tissues and death supervened. As far as I know this is the only recorded death from this complication.

REPORT OF CASES

CASE 1.—R. M. was a 3 months old white boy baby admitted to the Long Island College Hospital on May 30, 1937 because of fever, collapse and convulsions. The family and birth history were negative. The infant had been hypertonic since birth. For a month prior to admission there had been no weight gain. The present illness was characterized by fever of three days' duration. It fluctuated between 100 and 102 F. The cause of the fever was undetermined. Irritability was pronounced, and the infant slept poorly these three days. At 10 o'clock on the morning of admission the patient suffered a vasomotor collapse, including cyanosis and respiratory difficulty. The temperature rose abruptly to 107.5 F. but was reduced by hydrotherapy to 102 F. The stuporous state persisted for four hours, followed by hyperexcitability and irritability. Hospitalization was thereupon advised. Meanwhile, 10 cc. of 10 per cent calcium gluconate was injected into the muscles of the right buttock.

4. Shannon, W. R.: Tetany Syndrome in Newborn Infants: Remote Deposit of Calcium Salts Following Injection of Calcium Gluconate, *Am. J. Dis. Child.* 56: 1046 (Nov.) 1935

The admission examination revealed that the infant was acutely ill, decidedly cyanotic and in severe respiratory distress. Except for a slight left internal strabismus, the examination was negative. Blood count revealed 5,600,000 red cells, 13,000 white cells and 64 per cent polymorphonuclears. The urine showed 3 plus urine albumin and many red and white cells and cellular casts.

The diagnosis of pyuria was made. The therapy included intravenous glucose and sodium R-lactate injections. There was a favorable response, so that on discharge the patient was afebrile and the urine was normal. However, an abscess had developed at the site of injection, which was about an inch in diameter. This healed after several weeks, but a permanent scar remains.

CASE 2.—C. S. R., a white girl baby born on Nov. 19, 1942, birth weight 7 pounds (3.2 Kg.), had a convulsion on the third day after birth. Ten cc. of 10 per cent calcium gluconate was injected into the right buttock. Forty-eight hours after the injection the buttock became indurated and discharged purulent material for six weeks. After two months healing occurred.

CASE 3.—A. Y., a white girl baby, one of twins, was delivered on July 13, 1943 by low forceps. She weighed 4 pounds 11 ounces (2.1 Kg.). The mother and babies were discharged on

Areas of gangrene in case 3.

the eighth day in good condition. At the age of 14 days the mother observed two convulsions at the 2 a. m. feeding time. These convulsions began as a twitching of the face, followed by clonic movements of the left arm and leg. Her physician sent the baby to the hospital. There the infant received an injection of 10 cc. of calcium gluconate into each buttock for "possible tetany." There were no further seizures. On August 6, when the baby was 24 days old, she was discharged with the advice that a salve was to be applied to the buttocks, because they were infected where the needle had been inserted.

At home the mother noted that her baby "felt feverish" and the buttocks appeared worse. She therefore brought her to the Kings County Hospital (Long Island College Division) the following day, August 7.

The infant was well developed and well nourished and weighed 6 pounds 7 ounces (2.9 Kg.). She appeared acutely ill. Her temperature was 102 F. The examination on admission was normal except for both buttocks. These were equally affected. Each had an area of sloughing gangrene 5 by 5 by 1.5 cm. involving the ischioanal fat and gluteus maximus, as shown in the illustration. The ischial tuberosities, though not visible, were easily palpated. When the infant bore down, the perirectal tissues bulged into the right ischioanal space. Two days after the admission a surgical debridement was performed. The slough contained necrotic fat, connective tissue and muscle. Therapy consisted of sulfathiazole, orally and as an ointment for the buttocks, and two blood transfusions. In spite of these

measures the course of the infant's illness was steadily downhill. On the third day pneumonia set in. This was associated with the development of meningitis. Death followed on the fifth day after admission.

The autopsy was performed by Dr. Caspar Burn. The body, weighing 7 pounds (3.2 Kg.) and measuring 19 inches (48 cm.), appeared to be poorly nourished. There was no evidence of jaundice or petechial hemorrhages of the skin. The scleras and conjunctivas were clear and showed no petechiae, jaundice or hemorrhages. The buttocks presented pronounced ulcerations. The ulceration of the left buttock was oval, measured 2.5 by 5 by 3.5 cm. and was 1 cm. deep. It had a slightly irregular jagged edge and contained a small amount of yellow, necrotic material which covered the adipose tissue and the left gluteal muscles. The ulceration on the right buttock measured 2.5 by 5 by 3 cm. and was 1 cm. deep; this presented a yellow necrotic slough covering the gluteal fat; each ulceration was surrounded by a purple areola 4 to 5 cm. wide.

The pleural surfaces were smooth, glistening and translucent; no evidence of apical scars, tubercles or exudate was noted. The lungs had their usual shape and both lungs appeared to be collapsed except in the right lower lobe, which was firm and prominent. The external surfaces of the left lung showed numerous small, depressed, purple areas, whereas the whole right lung appeared a diffuse purple. On section the lung parenchyma was moist and exuded a frothy, pink material. The right lower lobe was dark beefy red and showed almost complete loss of lobular formation. The cut surface appeared smooth and darker red than usual, with this change being more prominent in the right lung than in the left. The bronchi and blood vessels showed no undue prominence, and the bronchi were lined by a smooth, white, glistening membrane. The hilar and tracheobronchial lymph nodes were not unduly prominent and showed no evidence of tuberculosis.

The scalp over the occiput showed two old hematomas about 6 cm. in diameter, most likely the result of the use of the scalp veins for intravenous therapy ante mortem. The anterior fontanel was diamond shaped, soft, 3 fingerbreadths in diameter, and showed no bulging or recession. The sagittal suture showed no overriding, and the posterior fontanel was closed. The bones of the vault of the skull were soft and showed no irregularities or fractures. The dura showed no evidence of hemorrhage or tearing. The meninges, except over the base of the brain, had lost their usual translucency, and within the subarachnoid spaces in this region there was an accumulation of fluid, greenish, purulent material. The brain was symmetrical and had well formed sulci and gyri, with no evidence of softening. The cerebellum was well developed. The blood vessels were thin walled and showed no aneurysms or arteriosclerosis. On section, the convolutions of the gray matter were pale and indistinct in outline but were regularly arranged. The ventricles appeared somewhat dilated and were filled with granular, pus-like material. The medulla and cerebellum showed the usual structures and did not appear unusual.

The skin was lined with stratified squamous epithelium, which stopped short at the edge of the ulceration. The corium of the skin contained sweat and sebaceous glands and hair follicles. The edge of the sinus consisted of collagenous material together with dilated and engorged newly formed capillaries and edema fluid. This process involved the base of the ulcer and to a slight extent the adjacent adipose tissue. There were a few foreign giant cells situated within the newly formed granulation tissue. Occasional polymorphonuclear leukocytes were present within the necrotic zones.

The remaining organs were essentially normal.

Bacteriologic examination of the heart's blood revealed *Staphylococcus aureus*, of the ulcers of the buttocks *Staphylococcus aureus*, *Bacillus pyocyaneus* and *Proteus vulgaris* and of the meninges *Staphylococcus aureus*.

The anatomic diagnoses were abscess of buttocks, sepsis, atelectasis of both lungs, bilateral hemorrhagic pneumonia and acute purulent basilar meningitis.

COMMENT

I have referred to the fact that previous articles have stressed the danger of injecting calcium gluconate intramuscularly in infants. The possible explanation lies in the fact that the cal-

cium, which is injected as a gluconate, is precipitated as a phosphate. The reason for this may be linked up with an increased phosphorus content of the blood serum in these cases. This is followed by coagulation within the local blood vessels, accounting for the necrosis and sloughing of the tissues (Tumpey¹).

Whatever the reason, the practice would still appear to be quite common. Furthermore, several excellent sources state that calcium gluconate may be used with safety intramuscularly. In Goodman and Gilman's textbook⁵ with reference to calcium gluconate the statement is made "It can be administered orally, intravenously or intramuscularly." No mention is made of the danger of using it intramuscularly in infants. The intramuscular injection of calcium gluconate is discussed in New and Nonofficial Remedies,⁶ which is issued under the supervision of the Council on Pharmacy and Chemistry of the American Medical Association. On page 454, under actions and uses of calcium gluconate, it states that it "is nonirritant for hypodermic or intramuscular use," "for children, 0.2 to 0.5 Gm. administered every day, on alternate days or every third day."

In view of the previous reports and these additional 3 cases, including a fatality, through sepsis not due to the drug, it would seem advisable to eliminate from the book and drug literature the use of calcium gluconate for intramuscular injection in infancy and specify the use of calcium gluconate in infants orally and intravenously only.

CONCLUSION

Three cases of abscess formation, including one death, following the injection of calcium gluconate intramuscularly in infants have been observed. It would appear advisable to avoid completely the use of calcium gluconate intramuscularly in infants and to restrict its use to the oral and intravenous routes. 340 Henry Street.

Council on Foods and Nutrition

The Council on Foods and Nutrition has authorized publication of the following statement.

GEORGE K. ANDERSON, M.D., Secretary.

POLICIES OF THE COUNCIL WITH RESPECT TO THE NUTRITIVE QUALITY OF FOODS

The Council on Foods and Nutrition has long concerned itself with the quality of foods. At first this interest involved primarily the purity of individual products and the truthfulness of statements made on package labels and in advertising. More recently the attention of the Council has also been given to the nutritional quality of foods and to the effect of a poor nutritional environment on the public health. A recognition of the importance of natural foods of both plant and animal origin in the maintenance of high standards of nutrition is paramount. It is necessary that the vast bulk of our diets in the way of carbohydrates, fats and proteins must come from products of this type. While certain nutrients found in these foods may be prepared synthetically, nutritional knowledge is incomplete, and unknown food factors undoubtedly exist which can be obtained only from natural food products.

It is well known, however, that many foods have suffered deterioration in their nutritional values as a result of the influences of modern civilization. Fruits and vegetables have been influenced by selective breeding to give better yields per acre and to have better keeping qualities in market or a better appearance. These induced changes have frequently brought about a reduction in the content of vitamins or minerals, or both, such that consumption of natural foods does not always insure adequate nutrition. The preference of the public for processed foods has frequently caused many of the valuable nutrients of a food to be discarded in favor of the nutritionally inferior, smooth, bland parts of the natural food. The use of

5. Goodman, L., and Gilman, A.: *The Pharmacological Basis of Therapeutics*, New York, Macmillan Company, 1944, p. 604.
6. *New and Nonofficial Remedies*, Chicago, American Medical Association Press, 1944, p. 454.

high temperatures in the preparation of certain types of foods further reduces their value to the body. Examples of these effects may readily be found in the chemically pure sugar of commerce, which lacks all but traces of its original vitamins and minerals, in white flour, from which the nutritious germ and outer coatings have been removed, and in the refined cereals, which undergo various processing procedures. These "denatured" foods have come to replace in large part the nutritious more nearly whole cereal grains which in former days supplied a considerable portion of the vitamins of the B group that enter the diet.

A consequence of this sophistication of the modern food supply has been to increase the difficulty of selecting diets that are suitable to maintain a good state of nutrition. Extensive educational programs have failed to bring about a greater appreciation and usage of the natural type of foods, such as whole wheat flour and bread. The continuation and extension of the preference for nutritionally inferior foods poses a question of grave concern with respect to the effect on the public health. This is especially disturbing, since animal experiments have shown that ill effects resulting from less than satisfactory diets may become obvious only after many years.

In view of these facts the Council wishes to encourage efforts to improve as far as possible the nutritive quality of all foods which contribute importantly to the American diet and which thereby constitute the food environment of the people. A genuine interest is taken by the Council in all attempts to raise the level of nutrients in products of the farm and in the institution of measures designed to retain in high degree the nutrients of foods during storage, processing and cooking. Programs of the dairy industry directed toward the production of milk of a higher and more uniform vitamin A content have had the support of the Council. Recently plans have been made to grant acceptance and use of the Council Seal to canned tomato and citrus juices, which contain a high natural content of vitamin C. The Council has also encouraged limiting consumption of sugar to such amounts as are needed to increase the palatability of foods with significant nutritional values.¹

In spite of all these efforts there exist now and will undoubtedly continue to exist for some time certain specific deficiencies in large segments of the population which can be remedied best through addition of the indicated nutrients to cheap, staple foods that occupy substantial places in the dietary.² The Council has favored and encouraged the addition of certain nutrients to selected foods for the purpose of overcoming these deficiencies by replacing as nearly as possible that which has been lost in processing or by making appropriate foods serve as carriers of dietary essentials which otherwise are inadequately supplied by many diets. Such additions considered to be in the interest of the public health are enumerated as follows:

Restoration (referred to as enriched in instances in which federal standards have been enacted)

of processed cereals with thiamine, riboflavin, niacin and iron.

of corn meal with thiamine, niacin and iron.

of hulled rice with thiamine, niacin and iron.

Enrichment of white flour with thiamine, riboflavin, niacin and iron.

Enrichment of white bread and rolls with thiamine, riboflavin, niacin and iron.

Enrichment of farina with thiamine, riboflavin, niacin and iron.

Fortification

of milk with 400 units of vitamin D per quart.

of oleomargarine with not less than 9,000 U. S. P. units of vitamin A per pound.

of salt with iodine.

The Council reaffirms its expression of opinion respecting the conditions under which additions of vitamins or minerals to foods will be approved as stated here and previously.³ As more

knowledge is acquired, some of the present "enrichment" programs may be modified. Some may be discontinued and new ones may be added. It is believed, however, that the present guiding principles will be maintained. In any case the addition of synthetics to natural foods must depend on the prevention of known deficiencies in groups of the population and not on the utilization of synthetic products which happen to be available at low cost. In the future the synthetics may be used more efficiently in animal nutrition to decrease the cost of animal products so that these materials may be more widely used in the human diet.

The Council disapproves of unlimited or indiscriminate fortification of general purpose foods with minerals, vitamins, amino acids or other nutrients. It likewise disapproves of artificial combinations of edibles designed to carry vitamins, minerals, amino acids or other nutrients for the use of the general public. It will use its influence to discourage the sale of products of the latter type except as special purpose products appropriately labeled to indicate their special purpose uses.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

PRIODAX.— β (4-hydroxy-3,5-diiodophenyl)- α -phenyl-propionic acid.— $\text{HO}(\text{C}_6\text{H}_4)_2\text{CH}_2\text{C}(\text{C}_6\text{H}_5)(\text{COOH})$.—M. W. 494.1. Priodax contains 51.37 per cent of iodine.

Actions and Uses.—Priodax is used as a medium for cholecystography. It is claimed to cause less nausea, vomiting and diarrhea than tetraiodophenolphthalein. The drug is excreted primarily through the kidneys.

Priodax is contraindicated in acute nephritis, uremia and acute disorders of the gastrointestinal tract. Side effects that may be encountered occasionally include pain on urination, nausea, vomiting, diarrhea, griping, headache, sensation of burning in the esophagus, generalized itching, dryness of the mouth, general weakness and flatulence.

Dosage.—The average adult dose is 3 Gm., although more may be given. The patient swallows the drug during or after a light fat-free meal in the late afternoon. Nothing is then eaten until the roentgenologic examination is completed the next morning.

Tests and Standards.—

Priodax occurs as a white or faintly yellowish, practically odorless and tasteless powder; soluble in alcohol and ether; slightly soluble in benzene and chloroform; soluble in both alkali carbonate and hydroxide solutions; insoluble in water. Priodax melts at 157 to 162 C., with decomposition.

Shake about 0.2 Gm. of priodax with 2 cc. of water and 2 cc. of chloroform: the chloroformic layer remains colorless (absence of free iodine).

Place about 0.3 Gm. of priodax in a 50 cc. glass stoppered cylinder, add 30 cc. of water, shake the contents for five minutes, filter through paper: separate portions of 10 cc. each of the filtrate yield a very faint opalescence with 0.5 cc. diluted nitric acid and 0.5 cc. silver nitrate solution (soluble iodides); no coloration or precipitation on saturation with hydrogen sulfide (salts of heavy metals).

Dry about 0.5 Gm. of priodax, accurately weighed, to constant weight over sulfuric acid: the loss in weight should not exceed 0.1 per cent. Incinerate 0.5 Gm. of priodax, accurately weighed, in a platinum crucible: the residue does not exceed 0.1 per cent. Transfer about 0.25 Gm. of priodax to a bomb tube; determine the iodine content by the Carius method: the amount of iodine found corresponds to not less than 50 per cent nor more than 52 per cent, when calculated to the dried substance.

SCHERING CORPORATION, BLOOMFIELD, N. J.
Tablets Priodax: 0.5 Gm.

SATURDAY, SEPTEMBER 29, 1945

TSUTSUGAMUSHI DISEASE

According to Blake, Maxcy and their colleagues,¹ the term tsutsugamushi disease is, on the basis of priority, appropriate to describe the condition which is also commonly known as scrub typhus or mite-borne typhus. The causative organism is *Rickettsia orientalis* and this name has the best claim to recognition. After thorough evaluation of the evidence, these investigators conclude that the disease, originally known as tsutsugamushi by the Japanese, is not confined to the river valleys of the islands of Honshu, Formosa and the Pescadores but has been reported from many localities in southeastern Asia and the adjacent islands in the Indian Ocean and southwest Pacific and in the coastal area of North Queensland.

Although there is some variation in clinical manifestations of the disease, particularly with regard to the frequency with which the primary lesion, or eschar, is found and the severity or case fatality rate, these variations are not greater than those which have been observed in Rocky Mountain spotted fever or classic louse-borne typhus. Consequently, although there may be some variation in virulence of the strains of the causative agent in different geographic areas, satisfactory evidence on which to base a recognition of two or more different diseases is not available.

The only vector which has been proved by animal experiments is the mite *Trombicula akamushi*, which occurs in Japan, Formosa, the Pescadores Islands and possibly elsewhere. The closely related species *Trombicula deliensis*, present in Sumatra, the Federated Malay States, India and Queensland, has also been incriminated, but crucial proof that this mite serves as a vector is still lacking. The principal host of tsutsugamushi fever in Japan is a field vole which has been found to

be naturally infected with *Rickettsia orientalis*. Because of its distribution, numbers and habits, this rodent probably serves as the principal reservoir host.

The principal early symptoms and physical signs of mite-borne typhus during the first five to seven days of the disease are headache, apathy and general malaise; fever, anorexia, bradycardia, congestion of the conjunctiva, lymphadenitis and a characteristic eschar. Only the presence of a typical eschar is sufficiently pathognomonic to establish the diagnosis at the first stage of the disease. A macular or maculopapular rash usually appears on the trunk between the fifth and the eighth day. The course is variable: the total febrile period in the mild cases may extend for twelve to fourteen days; when moderately severe, there may be signs of pneumonitis and encephalitis with recovery by lysis early in the third week; in the severe cases fever may last for three weeks or more with signs of severe pneumonitis and encephalitis. Collapse of the peripheral circulation and myocarditis are common in the severe cases. The Weil-Felix test becomes positive for *Proteus* OXK about the twelfth or fourteenth day of illness in most cases. The causative organism, *R. orientalis*, can be recovered readily from the blood of patients during the acute stage of the disease by the intraperitoneal inoculation of 0.2 to 0.3 cc. of blood in white mice. When positive, both of these laboratory procedures establish the diagnosis, but the disease is not excluded by a negative Weil-Felix test for *Proteus* OXK.

Blake and his colleagues also report the isolation of nine strains of a rickettsia from patients with mite-borne typhus of New Guinea. Inoculation studies were carried out with white mice, rabbits and hamsters. The latter animal proved to be excellent for studies of cross immunity. It was also found possible to cultivate these strains in the yolk sac of the fertile hen's egg. These investigations showed that the morphologic and pathogenic characteristics of both the human strains and the mite strains were identical and were similar to those described for *R. orientalis*, thus confirming the view that the mite-borne typhus of New Guinea is the same as tsutsugamushi disease of the Japanese Empire.

In a companion study, five different foci of tsutsugamushi disease in British and Dutch New Guinea and adjacent islands affecting American troops were investigated.² Strains of the etiologic agent, *R. orientalis*, were recovered by injection of white mice made with suspensions of two species of mites taken from wild rats. It was concluded that in local areas, at least, these mites, *Trombicula fletcheri* and *Trombicula walchi*, are vectors of importance. *R. orientalis* was recovered also from the brains of wild rats of a species common in

1. Blake, Francis G.; Maxcy, Kenneth F.; Sadusk, Joseph F., Jr.; Kohls, Glen M., and Bell, E. John: Studies on Tsutsugamushi Disease (Scrub Typhus, Mite-Borne Typhus) in New Guinea and Adjacent Islands: Epidemiology, Clinical Observations and Etiology in the Dobadura Area, *Am. J. Hyg.* 41: 243 (May) 1945.

2. Kohls, Glen M.; Armbrust, Charles A.; Irons, Edwin N., and Philip, Cornelius B.: Studies on Tsutsugamushi Disease (Scrub Typhus, Mite-Borne Typhus) in New Guinea and Adjacent Islands: Further Observations on Epidemiology and Etiology, *Am. J. Hyg.* 41: 374 (May) 1945.

the region. From laboratory studies of the strains recovered, it seemed almost certain that they were identical with human strains.

Tsutsugamushi disease is a definite entity with a known etiology and vector. The disease is widespread over an enormous geographic area and, because the vector is a mite, or possibly mites, living on several species of rodents, the spread of the disease to areas in which it does not now occur is a distinct possibility.

LOCAL PUBLIC HEALTH ORGANIZATION

Under the title "Local Health Units for the Nation" Emerson¹ reports for the Subcommittee² on Local Health Units of the American Public Health Association's Committee on Administrative Practice the status of local public health organization in the counties in the continental United States, exclusive of city health departments.

The committee was appointed under the provisions of a resolution passed by the American Public Health Association on Oct. 29, 1942, a similar resolution passed by the state and provincial health authorities of North America in 1944 and another passed by the House of Delegates of the American Medical Association on June 10, 1942. All these resolutions called, in effect, for the "earliest possible complete coverage of the nation's area and population by county, district or regional modern health service."³ This report is a large volume of 381 pages in which is set forth for each state the present status of local county health organization, together with a brief summary of the characteristics of the state, such as its urban or rural character, its health conditions and per capita buying power of its people, its hospital bed capacities and its public health law. The data for each state are set forth in a descriptive article, tabulations and a map showing where county health organization now exists.

This report of the factual data is the necessary first step by which the objectives set forth in the resolutions can be furthered. Combined approval from state health officials, public health workers and the medical profession should go far to expedite progress.

Until the most remote American family has access to accepted modern public health services, the nation's health will not be properly served. Expansion of public health activity, long advocated and pioneered by the medical profession, is a more sound and logical step

toward improving the nation's health than many grandiose plans for medical care.

The report contains observations which may briefly be summarized:

1. The delivery of the half dozen essential, primary services of public health should be a function of local government responsive intimately and personally to the needs of each community.

2. One third of the nation lives under substandard local health organization ill equipped to give basic minimum health protection at all times and to meet public health emergencies quickly and efficiently.

3. Approximately 20,000 local governmental units, in addition to some 70,000 school boards, are currently responsible for local health service in the United States.

4. The failure of local government in some states to organize workable administrative units of local health service is gradually removing the intimate and personal service of local health protection from the sphere of local to that of state government.

5. In order to provide the organization of workable administrative units of local health jurisdiction, each state should have enabling legislation, either permissive or preferably mandatory, whereby cities and counties may unite to form districts of suitable size for local health administration.

6. For approximately one dollar per capita every person in the United States could have minimum basic local health services under a professionally trained full time medical health officer, with appropriate associated professional and technical personnel and equipment.

7. This countrywide coverage could be achieved through 1,200 local health units.

8. The staff of 1,200 units such as described, if staffed according to the minimum standard, will require roughly 2,000 full time health officers and directors of medical education, all physicians. It will require part time participation of practically 6,000 local practicing physicians. In addition there will be needed roughly 26,000 public health nurses, 5,000 "sanitariums," 9,000 clerical and secretarial workers, 3,500 laboratory workers, 3,800 dentists, 540 health education specialists and 2,400 unskilled workers.

Here is a postwar employment project that offers tremendous opportunities for improving the nation's health. Its administration would be almost entirely local, with technical and financial aid where needed, through state health departments with federal participation. This is one answer to the problem of postwar improvement of the nation's health, as recognized in the platform of the American Medical Association.

Current Comment

RESIDENCIES AND FELLOWSHIPS

Elsewhere in this issue is a newly revised list of Approved Residencies and Fellowships for Veteran and Civilian Physicians. Included in this group are 736 hospitals whose educational programs have been investigated and approved by the Council on Medical Education and Hospitals. Education in these institutions is acceptable to the American boards. The hospitals are also eligible for the training of veterans under the G. I. Bill of Rights. The current list offers 7,666 residencies and assistant residencies as compared with 5,796 in 1943. However, in relation to the normal peacetime number of 5,256 residents reported in 1941 there is a total of 2,410 additional openings to meet the immediate needs of returning veterans. As the peak of medical demobilization is reached, hundreds of additional residencies will no doubt be available. Many of the approved intern and residency hospitals which have not yet attained a full development of educational services are now organizing new training programs or creating a further expansion of residencies already in existence. Hospitals in every part of the country have indicated a desire to participate in the postwar educational program as far as their facilities and teaching material will permit. In many institutions these plans are already well advanced, so that a considerable number of residencies now in process of investigation may soon be added to the approved list. The Council, in collaboration with the Committee on Postwar Medical Service and the American boards, will continue to exert every effort to provide additional educational opportunities of high quality for physicians seeking advanced hospital training on their return from military service.

THE HEREDITARY PATTERN OF BRAIN WAVES

The electroencephalographic records of 71 twins and 1 triplet were studied by Lennox and the Gibbses.¹ The 1 triplet was counted as 3 dizygotic twins. Fifty-five twins were monozygotic. In these the electroencephalographic tracings were considered identical in 85 per cent, not identical in 4 per cent and in doubt in the remaining 11 per cent. For the 19 dizygotic twins, lack of similarity in the electroencephalographic tracings was found in 95 per cent; they were alike in only 5 per cent. The Boston investigators further found that there was agreement between the physical and brain wave tests of identity in 88 per cent of the 74 twins (including the triplets), disagreement in 4 per cent and doubt in 8 per cent. In contrast with many of the established traits useful in judging the identity of twins, the electroencephalogram was found unstable and subject to frequent environmental changes. For example, the number of waves per second in the electroencephalograms increase with age, whereas irregularities tend to decrease. Another interesting feature of this study was the observation that the proportion of abnormal

electroencephalographic records was higher in this group of apparently normal twins than in the general population. These results suggest that in the absence of acquired variations the brain wave pattern is a hereditary trait. If dependable apparatus and experienced interpretation are employed, the electroencephalogram can be considered a useful method of extending human genetic studies and in tracing neuropsychiatric diseases which are associated with cerebral dysrhythmia. The possibilities of forecasting the inheritance of certain neuropsychiatric disturbances are obvious.

OFFICE SPACE FOR RETURNING PHYSICIANS

Among the most serious of the problems confronting the returning physician, as is already apparent, is the difficulty of securing suitable office space. In large communities, such as cities of over 100,000 population, the problem is apparently far more serious than in the smaller areas. In some larger cities physicians are even remodeling old houses into office space. At a meeting of the Board of Trustees of the American Medical Association in Chicago, members of the Board suggested that civilian physicians who have not been in military service be urged to offer available time and space, at least temporarily, to physicians who return from absences of two or three years in the service. Many a physician whose office is not fully utilized either in the morning or in the afternoon or even in the evening can make available time and space, as well as the use of his facilities to a returning physician, perhaps a member of his own hospital staff. This will enable the returning physician to get in touch with those whom he served previously and to begin rehabilitating himself in the practice of medicine before he has made a permanent choice of a location. The medical profession owes a large measure of gratitude to the 60,000 physicians who have given of themselves so freely and who have sacrificed so much for all of us. The least that can be done for such veterans is to make available to them an opportunity to begin the earning of a livelihood at the earliest possible moment.

DEFUNCT ORGANIZATIONS

A recent issue of the *New York Times* carried an advertisement, more than a page long, of the Chase National Bank. The announcement listed the names of persons or organizations of unknown address owning unclaimed funds of more than twenty-five dollars. Included in the list were the American Fund for French Wounded, the Friends of Belgium, the Committee for Dewey Arch, the Committee for Reception of Prince Henry, the National Sound Money League, the Babies Shelter Commission and the Non-Explosive Can & Device Company. No doubt the funds deposited for organizations like these were made with the best of intentions or eleemosynary motives. The absence of any claimant to the property is, however, a striking commentary on the facility with which new and poorly conceived organizations initiate their operations and the ease with which funds for almost any purpose can be obtained from credulous persons.

MEDICINE AND THE WAR

ARMY

TYPHOID REDUCED IN THE ARMED FORCES

As a result of use of the typhoid vaccine produced at the Army Medical Center, Washington, D. C., typhoid in the armed services has been reduced to less than 0.1 per cent. Sufficient vaccine to immunize a million persons a year is shipped out regularly in specially designed wirebound boxes, Col. S. D. Avery, chief of the division of biologic products, stated.

All Army, Navy, Coast Guard, Marine and Merchant Marine units overseas periodically receive yearly booster shots from the laboratory of the Army Medical Center. The Navy alone receives 15,000 bottles of typhoid vaccine monthly, shipped in special wirebound boxes perfected after thirteen years of research in packing and shipping by the U. S. Army Medical Department Professional Service School. The boxes, although dumped on beachheads during invasions, transported by jeep, donkey, camel or glider, delivered the glass bottled typhoid vaccine with virtually no breakage.

Wirebound boxes have also been designed by army medical men of the center to carry dysentery vaccine, a shigella typing kit that tests the type of dysentery, pollen extracts for the treatment of hay fever, Rh blood typing serum, live cultures and other biologic diagnostic reagents.

ARMY NURSE AWARDED BRONZE STAR

Capt. Ruth C. Tubergen, Army Nurse Corps, formerly of Elmhurst, Ill., was recently awarded the Bronze Star. According to the citation accompanying the award, "While on duty as chief nurse on the Army Hospital Ship *Emily H. M. Weller* from August 1944 to March 1945 she demonstrated outstanding qualities in support of combat operations. In the invasion of southern France, in the Italian combat zone and later in the landings on Leyte and Luzon in the Philippines a heavy responsibility was placed on the nursing service of this hospital ship. The excellent organization of the nursing service to meet the innumerable problems of severely wounded combat casualties was accomplished through her matchless energy and efforts. This entailed working day and night with little rest in dangerous water and under air attack over beachheads. Despite hardships created by tension over the battle area and the speed necessary to get the casualties aboard, she underwent fatigue and lack of proper rest to aid in the saving of lives and the maintenance of morale of the patients. Her achievements contributed unequivocally to the rapid recovery of many battle casualties and reflect great credit on the Nursing Service of the Medical Corps."

MOUNT SINAI HOSPITAL OVERSEAS UNIT RETURNS FROM FRANCE

After more than two years abroad, the Third General Hospital (overseas Unit of the Mount Sinai Hospital, New York) recently returned to the United States on the S. S. *General Stewart*. Although some of the physicians have already been detached from the unit for specialized service elsewhere, Col. Herman Lande, who served at the start as its executive officer and finally as commanding officer, and Major Ruth Chamberlain, its chief nurse, returned with a group of officers and an almost complete roster of the nurses who joined the unit more than three years ago.

The Third General Hospital, organized in 1940, was called into active service in August 1942, at which time it included 55 doctors and 120 members of the nursing staff. The unit arrived in North Africa in May 1943 and was assigned to its first site of operation, a captured German military hospital near Bizerte, on July 10, 1943. Although it was originally meant to be a 1,000 bed hospital, an expansion tent unit providing

for an additional thousand beds was immediately ordered and erected. During the first month of operation over 5,000 war wounded were admitted to the hospital; in addition, another 2,000 transient air evacuees were given medical and nursing care pending their evacuation to the rear. In May 1944 the unit was moved to Italy, where it turned former military barracks near Cassino, within sound of the battle, into a hospital in a short time and functioned throughout the Italian campaign. It landed in southern France on Sept. 29, 1944 as part of the 7th Army invasion and had operated at Aix-en-Provence since that date. Although organized as a 1,000 bed hospital, it rarely had less than 1,500 patients and treated as many as 2,000 at times. The hospital was formally relieved as of Aug. 27, 1945 and the personnel sailed for the United States on September 4.

DENTAL CORPS OFFICER AWARDED BRONZE STAR

Major Denton J. Rees, formerly of Oregon City, Ore., was recently awarded the Bronze Star. The citation accompanying the award read that, "while a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945, he performed outstanding services as mess officer and general supply officer for the camp. He voluntarily assumed the most difficult of duties, that of supervising the preparation and equitable distribution of meager and nutritionally improper rations among his fellow prisoners. Faced with noxious sanitary and housing conditions and the constant danger of food contamination by insects and vermin, he saw that the enemy-provided starvation rations were prepared in a manner as healthful and palatable as possible. His initiative and just administration were an inspiration to the entire prison camp."

ARMY AWARDS AND COMMENDATIONS

Major Benjamin Dickstein

The Soldier's Medal was recently awarded to Major Benjamin Dickstein, formerly of Philadelphia. According to the citation "Major Benjamin Dickstein, Medical Corps, Army of the United States, when flight surgeon of the 52d Troop Carrier Squadron, 1 Troop Carrier Command, heroically went to the rescue of the crew and passengers of a troop carrier transport which crashed and burned in a night takeoff, Sept. 16, 1942, at Pope Field, Fort Bragg, North Carolina. At the risk of his life he repeatedly entered the burning wreckage and with the assistance of one other extricated 14 injured and helpless men. A short distance from the wreck he administered first aid to the badly injured victims, continuing with this work even when the airplane exploded and showered him with burning debris. Major Dickstein, with great courage and complete disregard for personal safety, saved the lives of several of his comrades." Dr. Dickstein graduated from the University of Pennsylvania School of Medicine Philadelphia, in 1940 and entered the service Aug. 1, 1942.

Brigadier General Roy C. Heflebower

The Legion of Merit was recently awarded to Brig. Gen. Roy C. Heflebower, formerly of Washington, D. C. "From November 1941 to March 1945," the citation read, "he commanded the Medical Replacement Training Center (later the Army Service Forces Training Center) at Camp Barkeley, Texas, the largest installation of its kind in our history. With unusual foresight and thorough understanding of medical requirements he promptly developed a training program, instructing teaching personnel while producing sorely needed medical units. He exerted tireless effort to insure the com-

plete preparation of medical personnel for service with combat troops, a duty where their presence raised morale as well as saved lives. Many units were made ready for overseas assignments under his supervision, more than 130,000 soldiers were given individual training and over 11,900 officer candidates were qualified for appointment in the Medical Administrative Corps. The record of exceptional achievement by the Medical Department in all theaters of operations and the numerous commendations it has received were in great measure made possible by his outstanding ability to produce superior personnel and his skilful, energetic administration of his training program." General Heflebower graduated from the George Washington University School of Medicine, Washington, D. C., in 1906 and has been in the service since April 10, 1910.

Lieutenant Joshua P. Sutherland

The Bronze Star was recently awarded to Lieut. Joshua P. Sutherland, formerly of Haysi, Va., who "performed meritorious service for his fellow prisoners of war while confined at the German Stammlager IXB Prisoner of War Camp from December 1944 to April 1945. When offered an opportunity of moving to an officers' camp he voluntarily remained at this enlisted men's camp, realizing that the Germans had no intention of rendering medical service to the sick and dying men. Conditions under which these men lived were deplorable. The building used as a hospital was full of lice and bedbugs, poorly lighted and littered with rubbish, filth and disease. The Germans refused all requests for medicines, bandages, sedatives and sulfonamide drugs with which to administer medical aid. Working on a starvation diet and despite these deplorable conditions, he never faltered in his unstinting service to the 3,000 fellow prisoners whom he cared for during this period. When the German authority disclosed plans for evacuating this camp by forced marches he, through his remarkable tact and powers of persuasion, convinced the Nazis of the dire consequences of such a move and delayed it long enough to permit the camp to be liberated by American forces." Dr. Sutherland graduated from the University of Virginia Department of Medicine, Charlottesville, in 1943 and entered the service Feb. 11, 1944.

Captain Harry M. Brown

Capt. Harry M. Brown, formerly of Cicero, Ind., was recently awarded the Bronze Star. Accompanying the award was a citation, according to which, "while a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945, he performed outstanding services as ward surgeon and chief of the eye, ear, nose and throat service in a general hospital. With improvised, makeshift equipment and depleted medical supplies he labored against great odds and on a starvation diet. During an epidemic, the cause of which was unknown, he remained on duty day and night without relief to make more than eighty visual field examinations in an effort to determine the cause and possible cure for this strange disease. His devotion to duty, skill and initiative were highly instrumental in alleviating the suffering, saving the lives and maintaining the morale of his fellow prisoners of war." Dr. Brown graduated from the Indiana University School of Medicine, Indianapolis, in 1939 and entered the service April 5, 1941.

Captain Andrew Kerr Jr.

The Silver Star was recently awarded to Capt. Andrew Kerr Jr., formerly of Rochester, N. Y., who distinguished himself by gallantry in action against the enemy on April 17, 1945 in the vicinity of Aschersleben, Germany. When a motorized patrol encountered severe small arms fire and suffered numerous casualties, Captain Kerr answered the call for litter bearers by leading a group of aid men forward. Disregarding personal safety, he moved about the fire swept area, administering aid to the wounded, moving them to sheltered positions and supervising their evacuation. His courageous actions in defiance of danger, his aggressiveness and his devotion to duty were instrumental in saving many lives and reflect the high traditions of the armed forces. Dr. Kerr graduated from Harvard Medical School, Boston, in 1941 and entered the service Jan. 25, 1944.

Major William P. Rhudy

The Bronze Star was recently awarded to Major William P. Rhudy, formerly of Penn Yan, N. Y., who, "as chief of the surgical service, U. S. Army Hospital Ship *Emily H. M. Wedder*, rendered conspicuous and meritorious service from August 1944 to March 1945 in direct support of amphibious landings on enemy shores. In the initial operation in southern France this ship was assigned the task of evacuating the sick and wounded directly from the beachhead. Anticipating a heavy load of casualties under the most trying conditions, he organized the surgical service into three surgical combat teams. Under his personal supervision these teams performed 116 operations of all types, working day and night, under combat conditions with air activity harassing the beachhead and in waters not completely cleared of minefields. Again in the Italian combat zone this officer distinguished himself by his professional deftness in performing vital surgical operations. Later in the Leyte and Luzon operations he applied the surgical experience gained in southern France and in Italy to the severely wounded casualties, with distinctive results. His surgical contribution to the efficient operation of this hospital ship during these critical periods saved many lives and greatly enhanced the recovery of patients transported to rear base echelons." Dr. Rhudy graduated from Indiana University School of Medicine, Indianapolis, in 1924 and entered the service Aug. 19, 1942.

Major Charles J. Katz

The Bronze Star was recently awarded to Major Charles J. Katz, formerly of Oak Park, Ill., who, "while a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945," according to the citation accompanying the award, "performed outstanding services as surgeon, neuropsychiatric ward, in a general hospital. With improvised, makeshift equipment and depleted medical supplies, he labored against great odds and on a starvation diet. In addition to his neuropsychiatric tasks he served as medical supply officer, a position which required the use of great diplomacy in maintaining enduring relationships with the Japanese. His activity in conserving the mental health of his comrades under the depressing conditions of constant sickness, malnutrition and poor sanitation was an outstanding contribution to the well-being of his fellow prisoners of war." Dr. Katz graduated from Rush Medical College, Chicago, in 1937 and entered the service Sept. 25, 1940.

Major Ralph E. Hibbs

The Bronze Star was recently awarded to Major Ralph E. Hibbs, formerly of Oskaloosa, Iowa, who, "while a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945," according to the citation, "performed outstanding services as surgeon of the tuberculosis ward in a general hospital. With improvised makeshift equipment and depleted medical supplies, he labored against great odds and on a starvation diet. In addition to his medical tasks, he served as adjutant and registrar of the prison camp, assisting the commanding officer in administration and the maintenance of discipline in a most difficult environment. By his superior administrative ability and unusual devotion to duty he inspired his fellow prisoners of war." Dr. Hibbs graduated from the State University of Iowa College of Medicine, Iowa City, in 1936 and entered the service Feb. 20, 1941.

Captain Joseph R. Jehl

The Bronze Star was recently awarded to Capt. Joseph R. Jehl, formerly of Clifton, N. J., for "distinguishing himself by meritorious service in connection with military operations against an enemy of the United States from Oct. 19, 1944 to Jan. 5, 1945 in Holland, Germany and Belgium. In the hard fought engagements in Holland, Germany and Belgium Captain Jehl performed outstandingly as battalion surgeon. By introducing a system of interviews for reinforcements, he made possible their assignment to suitable posts, which resulted in a sharp reduction in cases of combat exhaustion. During the fierce action at St. Vith he repeatedly braved death to care for the wounded of many of our units. Captain Jehl's great courage and skill are worthy of the highest praise."

Dr. Jehl graduated from New York University College of Medicine, New York, in 1932 and entered the service in September 1942.

Colonel William C. Munly

The Legion of Merit was recently awarded to Col. William C. Munly of Washington, D. C., in recognition of exceptionally meritorious services during the Italian campaign. The citation read, in part, "Colonel Munly brought a long experience in military medicine and a thorough familiarity with conditions in the theater to the preparation of a series of

brilliant papers reporting medical problems in Italy. By virtue of his work, hospitalization was so disposed that all areas and all commands received adequate facilities. His reports provided the indispensable basis for many improvements in venereal disease control, in the health of the command, in sanitary conditions both focal and regional and in the efficiency of the medical service rendered United States forces in the Mediterranean theater." Dr. Munly graduated from the University of Oregon Medical School, Portland, in 1916 and entered the service in 1917.

NAVY

CONTRACTS VALUED AT \$11,500,000 TERMINATED BY BUREAU OF MEDICINE AND SURGERY

Victory over Japan found the Bureau of Medicine and Surgery holding \$40,000,000 in contracts for equipment, supplies, drugs and other material requirements, according to Vice Admiral Ross T. McIntire, Surgeon General of the Navy. Undelivered portions totaled approximately \$29,000,000, of which \$11,500,000 are being terminated.

An appreciable proportion of the material for which contracts are being terminated was not scheduled for delivery for several months, and this will minimize disrupting effects on the manufacturing and fabricating plants involved.

Another alleviating factor, Dr. McIntire pointed out, is that many of the cutback contracts are for drugs, biologic products, chemicals, surgical instruments, dental items and other supplies that can be channeled speedily into civilian markets. Most of the items for which completion and delivery are being canceled outright were of a special character intended for use in amphibious warfare and possess little or no value outside the armed forces.

Contracts aggregating \$17,948,000, or nearly one half of the original dollar value of the commitments, were for the more staple types of supplies and equipment whose requirements are not affected by the victory over Japan. Manufacture and delivery of the undelivered portion, totaling \$13,110,000, will be carried to completion.

In the "strictly for war" category were contracts having a face value of approximately \$10,000,000, of which 70 per cent were still in the factory stage on August 14, the day President Truman announced surrender of the Japanese. Commitments for all of this undelivered material are being terminated.

In surgical supplies the termination amounted to \$2,941,000. For surgical instruments and appliances which, in the main, were contracted for when invasion of Japan seemed inevitable, \$1,333,000 in contracts have been terminated or canceled; hospital and nursing equipment, \$1,912,000; office supplies, \$6,000; office equipment, \$19,000; dental supplies, none; dental equipment, \$164,000; field supplies and equipment, \$1,524,000; books, \$13,000.

Besides dental supplies, procurement items unaffected by the terminations and cutbacks are equipment and supplies required for the spectacle and optical program of the Medical Department, mortuary equipment and mortuary supplies.

NAVY AWARDS AND COMMENDATIONS

Captain Frank P. Kreuz Jr.

Capt. Frank P. Kreuz, Washington, D. C., was recently awarded the Bronze Star Medal in recognition of his achievement as senior medical officer aboard the U. S. S. *Washington* while in the rank of commander. The citation read "For meritorious achievement as senior medical officer serving on board the U. S. S. *Washington* in connection with operations against enemy Japanese forces in the Pacific war area from November 1943 to February 1945. Concerned solely with the health and well-being of our men, Commander Kreuz maintained the ship's medical department at the peak of efficiency despite the difficulties encountered as the *Washington* participated aggressively

in major combat operations. Directing all activities under his control with dependable judgment and resource, he initiated and constantly regulated vital health measures to meet the changing conditions prevailing on a combatant vessel, efficiently supervised the care of our sick and wounded and performed many difficult surgical operations with expert professional skill. A wise and practical counselor, understanding the peculiar mental and physical needs of men functioning under the strain of continuous combat, Commander Kreuz, by his outstanding ability and tireless efforts, insured the sound physical condition of the ship's company throughout a prolonged period of intensive operations: His cool courage and gallant acceptance of extreme danger and hardship served as an inspiration to all on board the *Washington* and upheld the highest traditions of the United States Naval Service." Dr. Kreuz graduated from Northwestern University Medical School, Chicago, in 1931 and entered the service. Dr. Kreuz is now serving in the Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Lieutenant Commander Harold W. Fleischer

Lieut. Comdr. Harold W. Fleischer, formerly of Washington, D. C., was recently awarded the Bronze Star for "heroic achievement as medical officer on board the U. S. S. *Gambler Bay* when that vessel was sunk by enemy gunfire in October 1944. The citation accompanying the award read "For heroic achievement as medical officer serving on board the U. S. S. *Gambler Bay* when that vessel was sunk by enemy gunfire during an engagement with major units of the Japanese fleet in the battle off Samar, Philippine Islands, on Oct. 25, 1944. With his ship disabled and forced to fall back in formation as a result of several hits from the terrific pounding by hostile cruisers when the Japanese steamed through San Bernardino Strait and attacked his task group with devastating force, Lieutenant Commander Fleischer repeatedly risked his life to care for the many casualties struck down during the fierce action. Despite the imminent danger of explosion, he fearlessly proceeded through burning smoke-filled areas to direct crew members in administering first aid and removing wounded from the stricken compartments, carrying on with consistent determination and aggressiveness until the abandon ship order was given. Adrift at sea for two days following the disaster, he continued to minister to survivors with unfailing efficiency, rendering valiant service and holding the loss of life to a minimum. By his keen foresight and superb professional ability in training the entire ship's company in fundamentals of first aid prior to enemy action, Lieutenant Commander Fleischer contributed to the saving of many men, and his outstanding fortitude and self-sacrificing efforts throughout upheld the highest traditions of the United States Naval Service." Dr. Fleischer graduated from Boston University School of Medicine in 1937 and entered the service June 24, 1942.

DISPOSITION OF STUDENTS ON ACTIVE DUTY IN NAVY V-12 PROGRAM

A recent release from the Navy Department, Bureau of Naval Personnel, contains the revision of Navy V-12 Bulletin No. 322 concerning disposition of students on active duty in the Navy V-12 Program. Medical, dental, theological, premedical, pre-dental and pretheological students will be released to inactive duty under the terms of reference (a), as previously interpreted, only on the stipulation that they continue their medical, dental, theological, premedical, pre-dental or pretheological training.

MISCELLANEOUS

FELLOWSHIPS IN PUBLIC HEALTH
AVAILABLE TO VETERANS

The New York State Department of Health has available a limited number of fellowships for physicians desirous of equipping themselves with the necessary field and academic experience for the practice of civilian public health on a full time basis. Six to twelve months of orientation and field work are provided under the guidance of experienced district state health officers followed by an academic year at a postgraduate school of public health where the master's degree in public health is earned. Fellowship provisions are generous and include tuition. Those completing the training are professionally qualified for appointment on the staff of most local and state health departments.

Applicants must possess certain basic qualifications, among which are United States citizenship, graduation from a medical school approved by the American Medical Association, internship of at least one year's duration in a general hospital approved for internship by the American Medical Association, and license to practice medicine in New York State or eligibility to take the examination to obtain such license. The upper age limit is 35 years.

Physicians interested in making application for a fellowship should write to the State Department of Health, Albany 1, N. Y.

WARTIME GRADUATE MEDICAL MEETINGS

California

A. S. F. Regional Station Hospital, March Field: Tumor Pathology, Dr. Edward Butt, October 16.

U. S. Naval Hospital, Santa Margarita Ranch, Oceanside: Penicillin in the Treatment of Syphilis and Gonorrhea. Lieut. Comdr. W. W. Duemling, October 11; Neurosurgery, Capt. Everett Dickinson, October 25.

U. S. Naval Hospital, Long Beach: The Streptococcus Problem, Lieut. Comdr. George R. Underwood, October 17.

U. S. Naval Hospital, Corona: Burns, Capt. H. T. D. Kirkbaum, October 11; False Biologic Reactions, Major Mark Beam, October 25; Allergies, Major Iredell Hinnant, October 25.

Letterman General Hospital, San Francisco: The Male Hormone: Clinical Indications and Mode of Administration, Dr. Hans Lissner, October 13.

Station Hospital, Camp Stoneman, Pittsburg: Suppurations of the Chest, Dr. Clayton G. Lyon, October 20.

Hammond General Hospital, Modesto: Diagnosis and Surgical Treatment of Brain Tumors, Dr. Edwin B. Boldrey, October 21.

Station Hospital, Fort Ord: Hemorrhagic States, Dr. Paul M. Angeler, October 27.

Regional Station Hospital, Oakland: The Use of Artificially Radioactivated Elements in Diagnosis and Therapy, Dr. Bertram V. Low-Beer, October 10.

New Mexico

Bruno General Hospital, Santa Fe: Symposium on Surgical Conditions of the Hand—Introduction of Subject: Major Frederick J. Fischer. Guest speaker, Major Lot D. Howard Jr., October 3. Symposium on the Pathogenesis of Tuberculosis—Introduction of Subject: Col. George J. Kastlin. Guest speakers, Drs. Arnold R. Rich, J. Burns Amberson and Col. Esmond R. Long, October 3. Symposium on Pulmonary Efficiency—Introduction of Subject: Major George C. Owen. Guest speakers, Drs. Andrew Courmand and Herbert C. Maier, October 4. Symposium on Sarcoidosis—Introduction of Subject: Major Samuel I. Kooperstein. Guest speakers, Drs. Arnold R. Rich, I. Snapper and J. Burns Amberson, October 4. Symposium on Surgical Diseases of the Spleen and Liver—Introduction of Subject: Dr. Kenneth E. Fry. Guest speaker, Dr. Allen O. Whipple, October 5. Symposium on Disseminated Vascular Disease—Introduction of Subject: Major Erich P. Hausner. Guest speakers, Drs. Arnold R. Rich and I. Snapper, October 5.

Pennsylvania

U. S. Naval Hospital, Philadelphia: Results of Penicillin Therapy of Syphilis in the European Theater, Col. Donald M. Pillsbury, October 5; Recent Advance in the Treatment of Acute Intestinal Obstruction, Dr. E. L. Eliason, October 26.

HOSPITALS NEEDING INTERNS AND RESIDENTS

The following hospitals have indicated to the Council on Medical Education and Hospitals that they have not completed their house staff quota allotted by the Procurement and Assignment Service:

ILLINOIS

Alexian Brothers Hospital, Chicago. Capacity, 261; admissions, 5,487. Brother Vincent, R.N., Superintendent (interns).
Women and Children's Hospital, Chicago. Capacity, 155; admissions, 3,538. Mrs. Edna H. Nelson, R.N., Superintendent (woman intern, October).

INDIANA

Lafayette Home Hospital, Lafayette. Capacity, 155; admissions, 3,751. Mr. T. E. Berg, General Manager (2 residents, mixed service).

KANSAS

University of Kansas Hospitals, Kansas City. Capacity, 400; admissions, 7,606. Dr. J. Harvey Jennett, Director (resident—anesthesia).

MICHIGAN

Saginaw General Hospital, Saginaw. Capacity, 151; admissions, 4,024. Mr. R. E. Raper, Superintendent (interns).

NEW YORK

Meadowbrook Hospital, Hempstead. Capacity, 275; admissions, 5,000. Dr. A. J. McRae, Superintendent (3 interns, April 1, 1946).

OKLAHOMA

University Hospitals, Oklahoma City. Capacity, 500; admissions, 6,610. Mr. Paul Fesler, Administrator (intern, October).

TENNESSEE

Nashville General Hospital, Nashville. Capacity, 337; admissions, 6,586. Mr. U. Phillips, Administrator (resident—ophthalmology-otolaryngology).

WEST VIRGINIA

Charleston General Hospital, Charleston. Capacity, 380; admissions, 10,439. Dr. John E. Cannaday, Director (interns).

CHINESE MEDICAL TRAINING
PROGRAM OF UNRRA

Dr. Leo Eloesser, who for more than thirty years was clinical professor of surgery at Stanford University, San Francisco, was recently assigned as teaching specialist in surgery for the Chinese medical training program of the United Nations Relief and Rehabilitation Administration.

The medical training project, which is part of UNRRA's relief program in China now rapidly getting under way, was planned jointly by UNRRA and CNRRA—the Chinese government relief agency—to train on a short term basis all types of workers to be used in emergency medical relief units. A detailed plan of operation for an emergency field medical service, which will utilize the trainees, has also been worked out by CNRRA and the Chinese National Health Administration.

Dr. Eloesser graduated from the University of Heidelberg, Germany, in 1907. He served as military surgeon in the United States Army in World War I.

APPOINTED DEPUTY DIRECTOR OF
HEALTH OF UNRRA

Dr. A. Hughes Bryan, formerly of Chicago, was recently appointed deputy director of health of the United Nations Relief and Rehabilitation Administration to succeed Dr. James A. Crabtree, who resigned effective September 10 to return to his duties with the U. S. Public Health Service. Dr. Bryan joined UNRRA in July 1944. Before his current appointment he was successively chief of the Nutrition Section and chief of Field Operations and Personnel in the Health Division.

ORGANIZATION SECTION

REPORTS OF OFFICERS

NOTE.—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion. The Report of the Secretary, additional sections of the Report of the Board of Trustees and reports of some councils, bureaus and departments will appear in subsequent issues of The Journal.—Ed.

REPORT OF THE BOARD OF TRUSTEES

To the Members of the House of Delegates of the American Medical Association:

The Journal of the American Medical Association

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION has adapted its pages to the needs of our country during the war period. A special section devoted to Medicine and the War has featured the work of the medical profession in the armed forces. Increasingly the pages of THE JOURNAL have reflected

current interest in social and economic problems related to medical practice. The prestige of THE JOURNAL is recognized by innumerable comments on items contained in its columns appearing in the newspaper and periodical press not only of this nation but of all the world.

Because of restrictions on paper supplies, no special effort to secure subscriptions was made in 1944; even so, 5,148 names

* This table gives the number of physicians (based on the 17th Edition of the American Medical Directory) in the United States, the number receiving THE JOURNAL and the approximate percentage in each state. Copies to physicians in the United States Army, Navy and Public Health Service are not included.

were added to the mailing list during the year, largely because of increased numbers of subscriptions entered through the Office of the Surgeons General of the Army and Navy.

The net paid weekly average circulation in 1944 was 109,828, as compared with 103,733 in 1943. The weekly average of copies printed during 1944 was 111,386.

The accompanying table 1 shows the number of Fellows and subscribers on the mailing list of THE JOURNAL as of

Jan. 1, 1945, and table 2 indicates the number of physicians in each state, the number receiving *THE JOURNAL* and the approximate percentage of subscribers in each state.

Special Journals

As a result of the shortage of paper supplies, it became necessary to reduce the number of pages in each of the special journals. The editorial boards have endeavored to maintain the quality of material published in the journals to the highest degree possible. No special editions of any of this group of periodicals were published in 1944, although a request for one special edition has recently been received.

The reviews of the literature in the *ARCHIVES OF SURGERY* (Progress in Orthopedic Surgery and Urologic Review), the *ARCHIVES OF INTERNAL MEDICINE*, the *ARCHIVES OF OPHTHALMOLOGY* and the *ARCHIVES OF OTOLARYNGOLOGY* have been continued, and there is a considerable demand for the review on orthopedic surgery.

A shortage of manuscript editors has made increasingly difficult the production of numerous scientific publications of the Association during the war.

Each of the special journals enjoyed increased circulation in 1944, this being especially true of the *ARCHIVES OF INTERNAL MEDICINE*. The total increase in circulation for the whole group was 3,745.

Income derived from the publication of the nine special journals in 1944 exceeded cost by the sum of \$107,962.37 as compared with a gain in the previous year of \$47,451.06.

Hygeia

The position of *HYGEIA* in the field of health education is now recognized as one of leadership. In the schools *HYGEIA* is a most useful reference. From every issue of *HYGEIA* condensations and reprints appear in innumerable digest magazines. Its articles and editorials have been widely copied by newspapers and have been the basis of many references on the radio. The success of the periodical is now unquestioned and the recognition it has received makes important definite planning for expansion in the postwar period.

The total number of subscribers on the *HYGEIA* mailing list on Dec. 31, 1944 was 135,685, an increase of 34,174 over 1943. The average monthly net paid circulation during 1944 was 118,830 as compared with 115,846 in the preceding year. It is gratifying to note that the circulation of *HYGEIA* among physicians in the past year increased slightly.

For the fourth consecutive year income derived from subscriptions and the sale of advertising space in *HYGEIA* has exceeded the cost of publication. Net income in 1944 amounted to \$68,117.81. Similar income in 1943 was \$52,758.79.

Library

Requests for the loan of 10,836 periodicals were received and filled by the Library of the American Medical Association in 1944. The requests came from physicians in military service in this country and overseas and from civilian physicians in each of the forty-eight states. Chicago libraries also availed themselves of the service to a considerable extent, the American College of Surgeons having had the loan of 498 periodicals, the Medical Library of Northwestern University School of Medicine 172, the John Crerar Medical Library 338 and the University of Illinois School of Medicine 45. Periodicals and miscellaneous medical reprints were lent to 291 physicians serving with the armed forces.

About 2,000 package libraries were lent during the year. Approximately one fourth of the requests for this service came from physicians in the various military services of the United States. The subjects most frequently requested during the year were the Rh factor; penicillin; military medicine, including various phases of tropical medicine, aviation medicine, burns and malaria; blood pressure; sulfonamides; anesthesia, and blood transfusion. Approximately 200 requests were

received from physicians overseas, who stated that they were desperately in need of material on certain subjects. Although the loan service could not be extended to those overseas, it was possible in every case to send duplicate material in the form of tear sheets and reprints from publications of the Association, which the physicians could keep for permanent reference. Miscellaneous reference questions numbering 4,500 were answered by letter and telephone.

Order and Mailing Department

The total number of orders handled through the Order Department in 1944 amounted to 80,649, a much lower number than in the previous year, and the number of units distributed was 287,088. More than 5,000 mail bags were used for mailing the 151½ tons of mail with which the Order Department was concerned.

In addition to more than 416,000 pieces of first class metered letter mail sent out, over 25,000 pieces of air mail and overweight first class mail and nearly 700,000 pieces of third class mail were handled in the Mailing Department during 1944. These figures do not include the several thousand letters mailed directly from various departments in the Association's offices.

Quarterly Cumulative Index Medicus

Unprecedented delay was experienced in the publication of the *QUARTERLY CUMULATIVE INDEX MEDICUS* for 1944. Owing to circumstances beyond control, the usual July-September issue had to be omitted. The decision to omit this issue was made in an effort to speed publication of the July-December volume, copy for which was sent to the printing department the first week in January 1945.

Practically no periodicals from European countries were received during the year. Approximately 17,944 foreign articles were indexed in 1944, about 63 per cent of this total representing Spanish and Portuguese articles. The remaining items were indexed from microfilms. Many more microfilms are on hand to be indexed but, because of the lack of personnel, it is not possible to cover this type of material very rapidly. The Library department was maintained with ten less assistants than formerly, which increased tremendously the work and responsibility of the remaining staff.

The net loss sustained in the publication of the *QUARTERLY CUMULATIVE INDEX MEDICUS* in 1944 amounted to \$9,131.89 as compared with a loss in the preceding year of \$19,784.97.

Council on Pharmacy and Chemistry

A noteworthy accomplishment during 1944 of the Council on Pharmacy and Chemistry was the creation of a Therapeutic Trials Committee to aid in the clinical appraisal of new drugs of promise. The Council is of the opinion that its facilities for contacts should be used to advance clinical research. It seems at the present time that this should take the form of mediating between manufacturers and the clinics; that the work should be confined to new products of definite and manifest promise, on which adequate laboratory work is available; that the Committee should have full jurisdiction over the choice of products that it sponsors; that the costs incurred in the actual trials should be the subject of contract between the manufacturer and the clinic conducting the trials; that plans for the operation of this committee should be developed, but that they need not be put into effect until the proposed peacetime plans of the Office of Scientific Research and Development and perhaps others concerning research which have been presented to Congress have crystallized. Details of the plan will be made available for all interested parties.

COUNCIL PUBLICATIONS AND REPORTS

During the year about 35,000 copies of New and Nonofficial Remedies, Useful Drugs, the Epitome of the Pharmacopeia of the United States and the National Formulary, Annual

Reprints of the Reports of the Council and Glandular Physiology and Therapy were distributed. Of this number New and Nonofficial Remedies comprised over 18,000 copies.

The figures for 1944 bring up to almost 461,000 the number of publications sponsored solely by the Council which have been distributed over the last twenty-two year period. Included in this figure are 203,000 copies of New and Nonofficial Remedies, of which about 95,000 have been complimentary paper bound copies issued to students in recognized medical schools.

During the year the Council began a series of short statements designed to be of special interest to the general practitioner. These statements offer information on the status of topics such as penicillin, serums and vaccines and vitamins. This series was favorably received and will be continued.

In addition to adopting for publication monographs and descriptions of drugs accepted for inclusion in New and Nonofficial Remedies, the Council adopted for publication various reports concerning the use of drugs in the prevention and treatment of disease. Deserving special mention are reports on the status of prophylaxis by *Hemophilus pertussis* vaccine, laboratory and clinical appraisal of new drugs, the status of penicillin, the use of vaccines for the common cold (a joint report with the Council on Industrial Health), the use of the electron microscope in the study of pathogenic bacteria, rickettsias and viruses, the comparative cost of vitamin mixtures, the local treatment of thermal cutaneous burns (a joint report with the Council on Industrial Health), the untoward effects of endocrine therapy, a comparison of the apothecaries' and the metric system, the status of germicidal soaps, the status of the antimeningococcic serum and meningococcus antitoxin, and a description of membership, activities, method of operation and attainments of the Council on Pharmacy and Chemistry.

RESEARCH

In addition to establishing a Therapeutic Trials Committee and to initiating and sponsoring research resulting from certain phases of problems facing the Council in its considerations, the Council's Committee on Therapeutic Research, which considers applications for research grants, issued during 1944 twenty-one grants ranging from \$125 to \$500. Many articles have been published during the year as a result of work done under these grants. The figures for 1944 bring up to 536 the number of grants that have been issued since the formation of the Committee in 1911.

ANNUAL MEETING

The Council held its annual meeting in October. The topics discussed and actions taken included the formation of the Therapeutic Trials Committee, stability and labeling of phenarsine preparations, status of thionaril, recognition of proprietary and nonproprietary names, principles of the American Medical Association Cooperative Medical Advertising Bureau, the sale of endocrine preparations to the public, scope of the Council publication *Useful Drugs*, increase of the annual budget of the Council's Committee on Therapeutic Research, Spanish and Portuguese translations of New and Nonofficial Remedies, labeling and dispensing of digitalis and purified principles, advertising of contraceptives, continuation of reviews and other activities of special interest to the general practitioner, unnecessary length of advertising brochures, and relation of vitamins and coenzymes and sulfonamide therapy.

MEMBERSHIP

During 1944 Drs. David P. Barr and James P. Leake were reelected to membership, and Dr. W. Barry Wood Jr., professor of medicine, Washington University School of Medicine, St. Louis, was elected to membership to fill a vacancy.

On April 1 the Council lost one of its most active and helpful members and American medicine one of its respected teachers and research workers when death came to Dr. Robert A. Hatcher. As a member of the Council from its creation in 1905 until 1943 and from then until his death as member emeritus, Dr. Hatcher gave unselfishly of his time without

thought of personal discomfort and deprivation. His contributions to Council progress were many.

MISCELLANEOUS

The Council has continued to provide its services and findings for the prosecution of the war effort and has supplied information to and cooperated with governmental agencies, regulatory and advisory, and with other bodies and organizations concerned with important problems dealing with the health of the armed forces and the civilian population.

The Council continued to enjoy cooperative relations with many agencies of the federal government and other bodies, and with representatives of a number of allied countries. There seems to be increasing interest in the work of the Council and the information it can provide on the part of scientists and others in many foreign areas. Correspondence from this source is increasing.

The changes initiated in 1942 and 1943 to expedite Council considerations have been received favorably and found effective. During 1944 further streamlining was effected to permit the Council to move even more quickly.

Educational activities were continued, the Council and its office providing much information for the medical profession, the general population and special groups interested in health education activities, special exhibits for loan, numerous addresses before scientific and lay audiences and on the radio and participation in many meetings concerned with the development, distribution and use of drugs intended for the diagnosis, prevention and treatment of disease.

The Chemical Laboratory

The work of the American Medical Association Chemical Laboratory during 1944 was devoted almost exclusively to the examination of products submitted for consideration by the Council on Pharmacy and Chemistry. This situation, although not unusual in comparison to earlier years, was brought about by the fact that the Laboratory has been operating with a reduced scientific and nontechnical staff. In October the Laboratory marked the completion of thirty-eight years of service to the medical profession.

WORK FOR THE COUNCIL ON PHARMACY AND CHEMISTRY

The Council on Pharmacy and Chemistry calls on the Laboratory each year to examine a number of new substances and to aid in the elaboration of suitable tests and standards by means of which uniformity in their composition and action may be assured. In 1944 the Laboratory gave consideration to standards for such substances as digoxin, a cardiac glycoside; hexestrol and monestrol, new synthetic estrogens; into-crostrin, a curare extract; iso-par, an anti-infective for external use; neostam and neostibosan, organic antimony compounds employed in tropical medicine, and priodax, a water soluble radiopaque organic iodide.

In addition, the Laboratory examined many other products submitted to the Council. These were largely new dosage forms of substances currently described in New and Nonofficial Remedies or for which standards appear in the official compendiums the U. S. P. and N. F. A partial list of the various substances encountered in this work includes amytal, ascorbic acid, estrogenic substances in oil, diethylstilbestrol, insulin from zinc insulin crystals, ephedrine hydrochloride, merbromin, nikethamide, phenobarbital, pyridoxine, riboflavin, various sulfonamides and their sodium salts, theophyllide and vitamins A and D.

The Laboratory aided the Council in connection with the preparation of several monographs and descriptions of dosage forms of various drugs, which were published in *THE JOURNAL* during the year. Assistance also was provided in the revision of New and Nonofficial Remedies, 1944, and in replies to correspondence on chemical subjects and questions of nomenclature.

WORK FOR OTHER DEPARTMENTS OF THE ASSOCIATION

The Laboratory has cooperated with the Bureau of Investigation by providing technical advice and a limited amount of chemical examination.

The Laboratory continued aid to the Library staff in the classification of chemical substances under proper designations and has been of assistance to the editorial department, the advertising committee and to other departments by means of technical advice.

The Director of the Laboratory was called on to assist in connection with the physical arrangements for the meetings of the scientific sections during the 1944 annual session of the Association.

Council on Foods and Nutrition

Throughout the year 1944 the Council on Foods and Nutrition has been carrying out its policy of limiting its scope of acceptance to special purpose foods and those few general purpose foods which are considered of particular public health significance. Producers of accepted foods which have been declared outside the present scope have been requested to discontinue use of the Council Seal. Use of this seal is still permitted in connection with the acceptable educational advertising materials of various groups of the food industry engaged in providing nutritional information to the public.

The Council has continued to work in harmony with the various agencies of the government and other groups concerned with food problems related to the war. The advice of the Council on nutritional matters has been made available to branches of the armed forces. The federal enrichment program for baked goods has continued to receive the Council's support, and active efforts have been made by the members to provide for the continuance of these nutritional benefits after the present emergency.

PUBLICATIONS AND COUNCIL REPORTS

Early in the year the Handbook of Nutrition, which had been prepared under the auspices of the Council, came off the press. It has had wide distribution with the sale of 3,000 copies. A revised edition of the pamphlet Food Charts, prepared jointly by the Council on Foods and Nutrition and the Food and Nutrition Board of the National Research Council, was completed. This contained the most recently available data on food values and enrichment regulations.

A number of reports were published expressing the Council's views on the nutritional value of certain foods, providing data on processed foods and offering general nutritional information. Many food products are being fortified with multiple minerals and vitamins. Milk is one of these foods, and the Council published a report rejecting a fresh milk containing added vitamins and minerals which was submitted for acceptance. It is the Council's opinion that only the addition of vitamin D to milk is justified from the public health point of view. In another report the nutritional value of oleomargarine fortified with vitamin A was reaffirmed and announcement made that Council acceptance was being withdrawn from individual brands of margarine because of the limitation of Council scope to special purpose foods. The Council reported on a machine known as the "Mechanical Cow," which mixes dried defatted milk solids, fat and water for the production of reconstituted milk. The resulting milk product has high nutritional value, being an excellent substitute for fresh milk. A final report was made on the analytic study of vitamin B content of all types of prepared cereal products, as authorized by the Board of Trustees. Copies of this material have been in great demand. Through another report attention was directed to the high nutritional value of wheat and corn germ, with a presentation of data on the composition of these food substances. One further report served to point out the inadvisability of using any chemical preservatives as home canning powders, either because of lack of effective sterilizing action or because of destructive effect on the food. The Cooperative Committee on Industrial Nutrition of this Council and the Council on Industrial Health prepared an outline of the efforts

made by all groups for the improvement of industrial nutrition. A resolution was adopted and published, summarizing these actions and making recommendations for continued improvement.

COUNCIL MEETINGS

Two meetings were held during the year. Many subjects discussed concerned problems of vitamins, their addition to foods and their preservation in foods. The Council adheres to the policy of restorative addition of vitamins to staple foods of the diet, with limited exceptions where fortification to higher than natural levels is considered in the interest of the public health.

The Council is anxious to encourage the production of high quality natural foods. Consideration was given to the plan of granting use of the Seal of Acceptance to tomato juice of specified high natural vitamin C content. It was decided to do this and to extend this use of the Seal to citrus juices and other foods. A resolution was adopted encouraging the development of improved feeding methods of dairy cattle and the practical application of these methods to raise the vitamin A content of winter milk.

NUTRITIONAL CONSULTATION

The Council has made its services freely available during the year to any individuals or groups seeking nutritional information. Because of war shortages it has been necessary to make substitutions in the ingredients of some processed foods, and the Council's opinion has been sought regarding these changes. Guidance has been given in the development of new products to insure worthwhile nutritional value. The Council office serves as a clearing point for nutritional information to other departments of the Association and for correspondence from physicians as well as for the food advertising in medical and other scientific publications. Cooperation has been continued with the agencies of the government in support of the declared policies relating to foods and nutrition. Numerous state and local nutrition committees have availed themselves of the Council's educational materials.

GROUP DISCUSSIONS

The Secretary of the Council participated in the educational endeavors of organizations concerned with nutrition. Papers were presented at the annual meeting of the American Dietetic Association, and articles on nutrition were prepared for professional and lay publications. The Secretary represented the Association in discussions on food and nutrition held under the auspices of the Norman Wait Harris Memorial Foundation of the University of Chicago and in the organizational meetings of studies on air transportation of fresh fruits and vegetables sponsored by Wayne University of Detroit. Attendance at the meetings on the Food and Nutrition Board of the National Research Council has been made possible through the kind invitation of this group, with which the Council works in close harmony.

MEMBERSHIP

Col. John B. Youmans, at the present time Director of the Nutritional Division, Office of the Surgeon General, was elected to membership on the Council to take the place of Dr. Tom D. Spies, who served for a period of five years.

SEAL REVISED

The Council Seal of Acceptance was revised to have included on it the full name of "Foods and Nutrition."

Council on Industrial Health

The Council on Industrial Health has witnessed during the past year many evidences of extraordinary interest in the health of industrial workers and the growing vitality of the whole industrial health movement. Much of this interest involves provision of medical coverage for all kinds of sickness and disability. Industrial accident prevention and care, occupational disease control, health supervision over workers and their education into ways of hygienic living have received constantly

improved study and application. The Council believes sincerely that in no other field are there comparable opportunities to improve scientific medicine and the distribution of medical services and to awaken a real appreciation of the accomplishments of medicine on the part of a very large portion of the total population.

GENERAL RELATIONS

The International Labor Conference in Philadelphia in May 1944 and the resultant report on medical care convinced the Council that the International Labor Office will shortly resume its preeminent place in industrial health activity. It is intended to keep that organization acquainted with the various activities of the Council. The Council on Industrial Health believes also that it has an important role to play in the development and maintenance of satisfactory scientific and cultural relations with Canada and Latin America.

On the whole, the Council's relations with governmental agencies, especially those responsible for the conduct of the war, have remained unchanged. The activities of the industrial hygiene divisions of the Surgeon General's Office in the Army, of the Bureau of Medicine and Surgery in the Navy Department, of the U. S. Public Health Service and of the U. S. Maritime Commission have been followed through direct participation in these functions by members of the Council or through attendance at Council meetings by representatives of these services. The War Production Board, through its Office of Labor Production, has concentrated attention on courses in safety procedure and has informed many labor-management committees in war plants regarding the health and safety services open to them.

Contacts with labor and management have been improved, but the Council is not altogether satisfied with them. The present intention is to extend these relations to as influential sources as possible, having in mind the necessity for medicine to maintain a detached and independent view of many aspects of labor-management affairs. Experiences around the conference table so far lead to the hope that some form of regular liaison can be organized to permit frequent discussion of mutual problems.

The Council has taken the position that the expanding importance of health activities in industry demands that the physician be responsible directly to top management and that activities relating to health be centered in and directed through the medical department. This attitude will be brought to the attention of manufacturers and commercial interests.

PROFESSIONAL RELATIONS

The field activities of the Council on Industrial Health have been considerably curtailed through travel restrictions and loss of personnel, but activity reported by many of the committees on industrial health in the state and county medical societies has been most encouraging. Educational programs have been kept up, state medical journals have assigned more space to the subject and interesting experiments have received strong medical support. One of these, the Fort Greene experiment in Brooklyn, N. Y., uses labor-management committees in plants as a means of distributing health education material to workers and of building up interest in the establishment of adequate plant medical programs. In nearby Astoria the health department supplies industrial nurses to plants provided that they, in turn, employ a physician, maintain proper records and make suitable space and facilities available.

The committees on industrial health set up in sections of the Scientific Assembly of the American Medical Association have been relatively quiescent. Projects under way at present include an inquiry into the effect of occupation on the menopause, a study of upper respiratory infections in industry, the evaluation of disability in the upper extremities, acoustic trauma, psychiatry in industry, industrial ophthalmology and methods of evaluating detergents and protective creams, all of which are illustrative of the many contributions which consulting specialties can make to better care for workers.

Other professional groups—dentists, nurses, nutritionists, engineers and technicians—have a real stake in the industrial

health field. Appropriate matters are discussed jointly with official agencies representing these groups. The Council has reaffirmed its opinion that public industrial hygiene activity should reside in bureaus operated by health departments and that the services performed by these bureaus—the Division of Industrial Hygiene of the U. S. Public Health Service and similar divisions of state and local health departments—merit full support from the medical profession at large.

PROFESSIONAL EDUCATION

A joint committee of the Council on Medical Education and Hospitals and the Council on Industrial Health was recently set in motion. The discussion up to the present time has suggested that undergraduate teaching in the field of industrial medicine should stress orientation and guidance rather than complete coverage. Every effort will be made to encourage medical schools, medical societies and others to develop refresher courses for physicians. The question of approval of in-service training for physicians in industrial medicine was not entirely settled. Standards need to be formulated and separately considered. Preferably, such training should be offered in affiliation with an established educational institution or hospital. The committee was greatly impressed with the plans for graduate teaching in industrial health at Wayne University Medical Center and elsewhere which are based on suitable correlation between medicine, toxicology, chemistry, sanitation and other disciplines. The development of a certification program depends on the proper conduct of such advanced educational centers. In general, it was agreed that the Council on Industrial Health should continue to exercise initiative in all phases of medical education affecting industry and that this joint committee should meet periodically to discuss new developments and consider new policies and standards.

The seventh Annual Congress on Industrial Health was not held, owing to the ruling of the Office of Defense Transportation about conventions. It is hoped, however, to collect the papers scheduled for presentation at the Congress and publish them in an Industrial Health Number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION as in past years.

Suggestions for motion pictures based on industrial health topics have been referred to the Council on Scientific Assembly in the hope that these can be prepared and distributed to interested professional and other groups.

INDUSTRIAL HEALTH EXAMINATIONS

The report on Industrial Health Examinations, which was approved by the House of Delegates in 1944, has since served as the basis for several interesting conferences with officials of the War Manpower Commission, the U. S. Civil Service Commission, the Office of Vocational Rehabilitation, the U. S. Public Health Service and labor, management and insurance groups. The return of many disabled persons to profitable employment has made it necessary to develop a selective placement program whereby physical capacity is matched as closely as possible with specific occupational requirements. Any successful plan must rest fundamentally on reasonable acquaintance of physicians with the nature of many jobs and on the proper interpretation of medical information by employment or placement officers. These discussions are likely to be one of the very significant contributions of the Council to the whole industrial health program and will involve studies and observations lasting over a number of years. In all other respects the Council expects to maintain leadership in the field of industrial health examinations and to continue to prepare supplementary reports on special kinds of physical examinations.

WORKMEN'S COMPENSATION

The Committee on Workmen's Compensation of the Council on Industrial Health was officially enrolled as an associate member of the International Association of Industrial Accident Boards and Commissions. Several conferences have been held with officials of that association, casualty insurance leaders, governmental agencies and others, and other meetings are in

prospect. Out of these discussions has come the recommendation that the Council on Industrial Health, the Bureau of Legal Medicine and Legislation, the Committee on Uniform Laws of the American Bar Association, the Legal Committee of the Industrial Hygiene Foundation and other interested groups collaborate on a model occupational disease law. Principles adequately reflecting the medical interests involved will be agreed on, and on that basis the Council has agreed to participate actively with these other groups. Conferences with these groups will pave the way toward simplification of report forms required by compensation commissions and insurance companies respecting industrial accident and disease.

Insurance companies have asked the Council to sponsor the preparation of reports on medical and surgical conditions about which questions most frequently arise in the adjustment of claims. The crystallization of prevailing medical opinion in these fields is regarded as a responsibility of the Council, and details for the formulation of such reports are being worked out currently.

The need of state medical societies for dependable aid and guidance in workmen's compensation affairs grows more evident daily. Such service can be supplied from the Council office on request because of ready access to relevant material in the files of the other Councils and Bureaus of the Association.

REHABILITATION

Rehabilitation is a major preoccupation of many official and independent agencies at the present time. Industry has always been concerned with the rehabilitation of its own injured and disabled. Now it is necessary to expand these facilities to expedite the reemployment of disabled veterans. In future years industry will deal more and more with the Federal Security Agency's Office of Vocational Rehabilitation as this agency expands its federal-state program. Since every rehabilitation problem rests fundamentally on medical diagnosis, disability evaluation and case management, the medical interest involved is enormous.

The Council on Industrial Health has therefore created a Committee on Medical Policy in Rehabilitation and Employment made up of its existing committees on Rehabilitation, Physical Examinations and Workmen's Compensation. This combined committee regards the following activities as essential if medicine is to occupy a position of leadership and influence in the rehabilitation picture:

1. A central clearing house will be established in the Council office to collect and disseminate information about the rehabilitation activities of all interested agencies.
2. Committees on industrial health or other appropriate units in state medical societies will be asked to maintain contact with the activities of state rehabilitation agencies. Other medical organizations will concern themselves with special procedures involving specific kinds of disability. Regular reports will be requested and will be used as a basis for integrated and correlated medical service.
3. Special reports will be prepared on various methods of restoration, on vocational guidance and training and on selective placement of the handicapped. Other educational services will be developed as indicated.

COOPERATIVE ACTIVITIES

In addition to the activities mentioned, the Council has asked and received cooperation from most of the established agencies of the American Medical Association. The Committee on Industrial Nutrition, created jointly with the Council on Foods and Nutrition, has concerned itself with the food requirements of workers, vitamin administration and, more recently, sanitary standards for preparation and serving of food. Reports on thermal burns and on cold vaccines were published in cooperation with the Council on Pharmacy and Chemistry. Matters relating to rehabilitation and resuscitation have been considered with the Council on Physical Medicine. Contacts with the Council on Medical Service and Public Relations have demonstrated many common problems needing joint consideration. On

many occasions the Council has profited through consultation with the Bureau of Health Education and the Bureau of Legal Medicine and Legislation.

HEADQUARTERS ORGANIZATION

Personnel and facilities to take care of the constantly enlarging scope of activities will be secured as soon as they become available. Assistance is necessary to conduct the field services of the Council, to promote the clearing house and special report program jointly with the consulting committees representing the sections of the Scientific Assembly and other societies and to develop the medical phases of workmen's compensation, reemployment and rehabilitation. Reorganization along these lines will result in much more effective service to the profession, to labor and to management.

INDUSTRIAL HEALTH SERVICE FOR FEDERAL EMPLOYEES

Hearings were conducted by a subcommittee of the House Committee on Civil Service relative to a bill which proposed to make available to employees of the federal government the same kind of medical service commonly provided by private industry. Representatives of the Council who were called to testify approved the intent of the legislation, since it conformed to standards developed by the Council and included safeguards characteristic of private industrial medical service plans.

PHYSICAL FITNESS

Much of the program of the Council lends itself directly to the promotion of positive health and physical fitness in the industrial population. The Council therefore is prepared to collaborate in all effective ways in the physical fitness movement and has been asked to participate in certain details of organization and education of employers and workers.

POSTWAR DEVELOPMENTS

The war has intensified interest in industrial welfare. The Council expects this interest to continue into the postwar era. In preparation, therefore, the Council has outlined lines of inquiry and development which will improve the contribution of medicine to industrial health and safety. The occupational dermatosis problem must be attacked through fundamental research and education. Serious limitations in personnel dictate the construction of training centers for industrial hygienists and toxicologists. Present trends indicate a strong demand for a practical industrial mental health program. The relationships of preventive medicine and public health administration to industry need clarification, having particular reference to case finding programs, immunization, nutrition, recreation and housing. Industrial physicians must know how to deal with active or latent tropical disease in applicants who present themselves for employment. The frequency and severity of industrial disabilities must be reduced through prevention and adequate case management. In the latter connection physical medicine, occupational therapy, functional exercise and reconditioning have much to offer. The place of the physician in industry, the trends toward the extension of industrial medical service to cover nonoccupational illness or injury, the labor-management approach to health and safety problems all call for elaboration of specific medical policy. The Council on Industrial Health, confronted with questions of this magnitude, believes that its career of useful activity has barely started.

Bureau of Health Education

Wartime difficulties which affected the work of the Bureau in 1943 were intensified in 1944, largely because of inavailability of adequate personnel.

CORRESPONDENCE

The Bureau mail was about the same in total quantity as in 1943. Correspondence with physicians and cooperating agencies increased from 2,724 to 3,825; question and answer letters increased from 6,065 to 6,598. Queries received from museums and exhibits dropped from 1,846 to 1,259, perhaps a reflection

of curtailed travel and canceled meetings. The total of 11,718 as compared with 11,259 the preceding year indicates little overall change in the volume of correspondence.

BUREAU PUBLICATIONS

The Director of the Bureau has prepared material for THE JOURNAL and for HYGEIA. Fourteen articles prepared by the Bureau were published in periodicals other than those of the Association.

RADIO

The radio work of the Bureau falls into four principal classifications: network broadcasts, electrical transcriptions, script library and special broadcasts.

The network program was continued into its eleventh consecutive year of dramatized broadcasting on a nationwide network of the National Broadcasting Company. Still keeping the theme and title "Doctors at Work," in 1944 the fourth "book" or series under this title was broadcast with the subtitle "Doctors at War." Beginning January 8 twenty-six programs were scheduled and twenty-three actually broadcast. Time was relinquished for a broadcast by the President of the United States on one occasion and on another for a recruiting program for the Cadet Nurse Corps by the Office of War Information. The closing program of the series, scheduled to be a pick-up by shortwave from foreign theaters of war, was canceled because it might have coincided (as it actually did) too closely with D day in Europe. An unsolicited letter of commendation from the Surgeon General of the U. S. Army was received when the program closed at the end of June:

WAR DEPARTMENT

Services of Supply
Office of the Surgeon General
Washington

28 June 1944

Dr. W. W. Bauer
The American Medical Association
535 North Dearborn Street
Chicago, Illinois
Dear Dr. Bauer:

With the close of this year's "Doctors At War" radio series I wish to again thank you and your colleagues for your excellent service to the Medical Department of the United States Army.

This program is consistently good and I know from the correspondence which I have personally received that it has inspired confidence and faith in the American public in the work of the Medical Department during this crucial war period.

Sincerely yours,
NORMAN T. KIRK,
Major General, U. S. Army
The Surgeon General.

The script library again shows a shrinkage. At one time there were available 1,000 titles divided among fifteen minute, ten minute and five minute talks. The demand for five minute talks dropped so low that as of Jan. 1, 1944 the five minute list was discontinued but the best talks in the list were combined by subjects and added to the fifteen minute list in a series of scripts entitled "Medical Echoes from Here and There." Each script in this series consisted of a contribution from two or more sources. Suggestions to local broadcasters were that several voices should be employed in broadcasting these scripts, thus giving more variety and interest to the presentation. Despite the shrinkage in this service, twelve state and county medical societies or their auxiliaries utilized the service for the first time in 1944. The total distribution of radio talks was 1,352 to a total of twelve county medical societies, seven county health departments, one hospital and one county nursing service.

Electrical transcriptions, first made available in 1943, constituted the most important development in the work of the Bureau in 1944. Starting with an experimental project broadcast over WLS, as described in the annual report for 1943, a series of sixteen programs was developed under the title "Before the Doctor Comes." At about the same time another series on wartime medical problems entitled "Medicine Serves America" was prepared. These constituted the nucleus of radio electrical transcriptions at the end of 1943. Also becoming available early in 1944 was a series of twelve interview recordings entitled "Dodging Contagious Diseases."

Early in 1944, in cooperation with the Chicago Public Schools, a series of twelve programs was developed under the title "Health Heroes." These were stories at the level of fourth and fifth grade elementary school children, each story containing a health lesson, first broadcast to the Chicago schools by FM radio. They were later rebroadcast for records. This series of records has been offered to the schools for permanent use at \$25 per set.

In the late spring of 1944 it became obvious that electrical transcriptions were going to be a success. Originally ten sets of each series were ordered, and these were distributed on a loan basis. It soon became apparent that more would be needed. Enthusiastic promotion by the medical societies of Arizona, Wisconsin, Texas and Pennsylvania and numerous loan applications from county medical societies and health departments depleted the loan stock so that it was increased, first to twenty, then to twenty-five and at last to thirty sets of each series. The loss by breakage and failure to return loaned sets has been surprisingly small. On the basis of the loan records it is estimated that in 1944 there were approximately 1,052 local broadcasts from these transcriptions. Because of the obvious and rapid growth of demand, the Board of Trustees made provision for the preparation of a series of dramatized recordings and for the purchase of additional pressings of series already in circulation.

During the summer of 1944 a dramatized series of twelve programs entitled "Live and Like It" was written and produced and is now in circulation in addition to the other series.

During the autumn of 1944 a series of interview and round table programs was recorded dealing with health problems in adult life and with the leading causes of aging and of death. This was entitled "More Life for You." In this series twenty-two prominent physicians were interviewed.

With continued evidence of the demand for transcribed broadcasts, the Board of Trustees in September 1944 authorized recording of the following series:

- A. "Guardians of Your Health," thirteen programs devoted to public health.
- B. "Keep Cool," twelve programs on summer health hints.
- C. Twelve additional dramatizations, possibly an extension of the series "Live and Like It."
- D. A series on child health problems other than communicable disease.

As usual, special radio broadcasts were arranged during the Chicago session. In spite of shortage of radio time due to high advertising sales and extensive governmental demands, to say nothing of a political campaign, broadcasts on the Blue Network, the Columbia Broadcasting Company, the National Broadcasting Company and local stations WIND, WCFL, WJJD and WAAF were made with the generous cooperation of the network and managers of the stations mentioned. The Presidents, outgoing and incoming, of the American Medical Association and Army and Navy medical officers made the broadcasts.

MEETINGS AND CONFERENCES

The Director traveled 27,375 miles to address audiences or attend meetings in nine states. Audiences addressed numbered eighty-nine and totaled 28,595 persons. In addition to audiences addressed, the Director participated in thirty-eight conferences and meetings. Thirty-three engagements were declined or had to be canceled because of previous commitments, travel difficulties or other causes.

HYGEIA CLIPPING COLLECTIONS

The large number of physicians in military service and the heavy demands on those remaining has decreased local speaking by doctors to lay audiences. Therefore, HYGEIA clipping collections were lent only 108 times in twenty-five states. The principal topic called for was "Ten Points in Healthy Living."

HEALTH PUBLICATIONS

Owing to the necessity for conserving paper, only a small number, twelve new titles, of new publications were added in 1944, while two titles were discontinued. The total distribution of Bureau publications was 217,879 items.

COÖPERATIVE RELATIONSHIPS

Joint Committee on Health Problems in Education of the National Education Association and the American Medical Association.—The 1944 meeting of this committee, held at the headquarters of the American Medical Association, was very successful. The committee elected Dr. Thurman B. Rice chairman to succeed Dr. Charles C. Wilson, Dr. A. J. Chesley secretary to succeed Dr. W. W. Bauer, and Dr. Duggan was elected vice chairman. Dr. Thurman B. Rice was reappointed for the five year term expiring in 1949. Dr. George M. Lyon was absent by reason of his duties in the U. S. Navy. Superintendent Willis A. Sutton and Dr. Glenville Giddings sent proxies.

Subjects dealt with on the agenda of the Joint Committee were as follows: Relationships of the Joint Committee to the National Conference on Cooperation in Health Education were discussed; the committee published a list of its publications with prices and information as to availability; the committee adopted a resolution on health education in secondary schools; the committee adopted a statement on wartime administration of drugs in schools prepared by Dr. Austin E. Smith; a hard of hearing report prepared by Howard A. Carter was submitted to a mail vote; a report on ultraviolet lamps for disinfecting purposes in schools was adopted and ordered published; a small subcommittee was appointed to endeavor to make a brief statement on food rationing and its effect on nutrition of school children.

U. S. Children's Bureau Advisory Committee.—The Advisory Committee to the U. S. Children's Bureau met in December. In November the Children's Bureau called a conference of official representatives of medical and other groups interested in the EMIC program.

The status of this program has not changed except in scope and size. The appropriation for the 1945 fiscal year was 40 million dollars, and it was expected that more than three hundred thousand wives of servicemen and their infants would be cared for. The position of the medical profession apparently remains unchanged, namely, complete accord with the purpose of care for servicemen's wives and children but dissatisfaction with the administrative methods of the Children's Bureau by which all blame for errors and mistakes falls on the local administrators and the major share of the credit for success goes to the federal agency. Some physicians are caring for soldiers' wives and infants gratis and declining to accept remuneration from the government, while others are cooperating in the program under protest.

The details of the situation reported to the Trustees in the 1943 annual report of this Bureau remain essentially unchanged and are therefore not repeated.

National Committee for Boys and Girls Club Work.—The work of this committee proceeds routinely, with nothing of special interest to report in 1944.

National Congress of Parents and Teachers.—The work of the National Congress of Parents and Teachers follows along the same general lines, but it becomes increasingly difficult and in many places impossible to have children examined because there are simply not enough doctors and dentists to make examinations.

American Public Health Association.—The Director continues to be active in the affairs of the American Public Health Association. He is serving as an elective member of the Governing Council for a three year term expiring in 1947 and is a member of the Committee on Professional Education, one of the association's major committees, as well as of the Accident Prevention Subcommittee of the Committee on Administrative Practice. He is chairman of the Health Education Section's Committee on Health Education in Hospital Outpatient Departments and Clinics.

At the 1944 meeting of the American Public Health Association there was adopted a report entitled "Medical Care in a National Health Program." This report practically called for compulsory federal health insurance. It was prepared by a subcommittee of the Committee on Administrative Practice,

adopted by the committee and adopted by the governing council of the association after that body had rejected a proposal that the report be received and a conference committee be appointed to meet with representatives of the American Medical Association and the American Dental Association. The report and an editorial comment were published in THE JOURNAL, Oct. 14, 1944.

National Conference for Cooperation in School Health Education.—This conference did not meet in 1944, but the executive committee functioned by correspondence and by informal conferences among its members at other meetings. Steps are being taken to procure financial support to conduct some studies in school health procedures in 1945. Mr. Mayhew Derryberry of the U. S. Public Health Service is chairman of the conference. The Director of this Bureau is a member of the executive committee.

U. S. Government Agencies.—The U. S. government agencies with which the Bureau has cooperated, or to which the Bureau has furnished information during the year, are as follows:

Federal Security Agency: Office of Education; Public Health Service. War Department (U. S. Army): Office of the Surgeon General; Office of the Air Surgeon; Army Service Forces; Bureau of Public Relations; Nutrition Research Laboratory; Army Nurse Corps; Liaison Office, War Department and American Medical Association; Preventive Medicine Service; Technical Information Branch.

Navy Department: Audiovisual Education Branch; Bureau of Medicine and Surgery; Public Relations Branch.

Department of Agriculture: Farm Security Administration; Agricultural Research Administration.

Department of the Interior: Office of Indian Affairs, Denver.

Department of Labor: Children's Bureau.

Office of Coordinator of Inter-American Affairs.

The United States Chamber of Commerce also has received the cooperation of the Bureau.

MISCELLANEOUS

The staff of the Bureau includes two trained guides, who made numerous tours of the building with guests.

The Bureau continued to compile information on medical research and to distribute it in response to requests.

The Bureau furnished questions and answers to *HYGEIA* for publication; forty-seven were published. In obtaining these answers, the Bureau consulted twenty-five experts outside the American Medical Association building. All *HYGEIA* galley proofs and page proofs were checked in the Bureau.

The Bureau continued its cooperation with the Woman's Auxiliary in its various activities.

The Assistant Director continues to be a member of the Medical Advisory Committee of the Chicago chapter of the American Red Cross and the Veterans Rehabilitation Committee of the Chicago Tuberculosis Institute.

On suggestion of the Joint Committee, the House of Delegates modified its resolution adopted in 1943 dealing with biology teachers. The Bureau is responsible for disseminating information on this matter and has done so to the best of its ability.

The postgraduate students from the U. S. Public Health Service and the Kellogg Foundation numbered 40 in 1944 instead of 29 as in the previous year. They spent a week at the Association's offices and were given an intensive course of instruction, observation and demonstration covering the work of the American Medical Association. They came this year from the University of North Carolina, University of Michigan, University of Illinois and the Health Department of the Province of Quebec. In addition to the large group, the following students spent several days or a week in similar individual observations: Dr. Herman San Martin of Chile, Drs. G. Castillo and Mario Queiroz of Brazil, Mrs. Mary Carr Baker of the Massachusetts State Health Department, Miss Frances C. Hunter of the California Department of Public Health, Miss Andromache Tsongas of the Harvard School of Public Health, Miss Elizabeth Dean of the Illinois State Health Department and Mr. I. R. Vaughn of the North Dakota State Health Department.

(To be Continued)

Washington Letter

(From a Special Correspondent)

Sept. 24, 1945.

Disabled Veterans Ask "B-29 Solution" of Artificial Limb Problem

While American servicemen get ultramodern medical treatment, those who lose a limb are fitted with "horse and buggy" artificial arms and legs, according to three medaled Walter Reed Hospital patients testifying before the Kelley Subcommittee on Aid to the Physically Handicapped, the chairman of which is Representative Augustine B. Kelley, Democrat of Pennsylvania. The three men dramatically stressed the need for a federal long range program toward developing improved artificial limbs. "We want the government to attack this problem just as it attacked the problem of building the B-29—by turning it over to technicians working on a full time basis," stated First Lieut. Sol Rael, 24, of New York, tankman, who lost an arm in Germany to a sniper's bullet, Howard Morse, 36, New York coast artilleryman, whose left leg was amputated after he was hit by shell fragments in the Philippines, and Irving Krieger, 34, East Orange, N. J., whose left leg was lost in a mine blast in France. Their comments came out in a spirited round table discussion with Representatives Kelley, William J. Green, Democrat of Pennsylvania, and Sherman Adams, Republican of New Hampshire.

Army Mismanagement of Medical Manpower Charged

Col. W. Paul Holbrook, testifying before the Senate Military Affairs Committee as an investigator to survey army medical needs, said that too few doctors had been used by the Army at the front and too many behind it. He claimed that the armed forces had taken 60,000 doctors for the 12,000,000 men in uniform and had left only 90,000 at home to care for 120,000,000 civilians. He declared that there were too many doctors for service personnel and that determining the number of physicians required on the numerical strength of units was a "fundamental fallacy" of the army system. Colonel Holbrook said that 50 doctors assigned to a 15,000 man infantry division were "far too many for preventive medicine to healthy young men, yet far too few on the field of battle." Despite this, he pointed out, this number of doctors was assigned to a division whether or not it was at the front or in an inactive theater.

More Hospitals and Doctors Required by Veterans Administration

Veterans Administration officials are now checking on additional hospital and medical personnel needs of the agency, expected to be heavy as increasing numbers of servicemen are discharged. Gen. Omar N. Bradley, new veterans administrator, with Major Gen. Paul R. Hawley, acting Veterans Administration Surgeon General, and Brig. Gen. H. B. Lewis, acting director of organization, and other aides, conferred at Atlanta, Ga., with agency officials from eight Southeastern states.

Navy to Release 1,678 Reserve Medical Officers

Vice Admiral Ross T. McIntire, Surgeon General of the Navy, informed the Senate Military Affairs Committee that the Navy would release 1,678 of its 12,000 reserve medical officers under the point system by January 1. He explained that they will be released at the rate of 880 a month, starting January 1, and that 8,000 will be out by the time the Navy researches its postwar goal of 550,000 officers and men next September 1. An effort will be made to keep medical discharges up to the pace of demobilization of fighting personnel.

Dr. Parran Maps Six Point Health Program for All Citizens

A six point program to provide "equal health opportunities for every citizen" was outlined by Surg. Gen. Thomas Parran of the U. S. Public Health Service at the 122d opening session of George Washington University School of Medicine. He was guest of honor at a luncheon given by Dr. Walter A. Bloedorn, dean of the school, at the Mayflower, attended by Army, Navy and District medical leaders. Dr. Parran's program called for (1) an integrated system of hospitals and health centers radiating from a central unit to smaller local and rural communities;

(2) sanitary environment, covering water, milk, food and sewage, which would eradicate such diseases as malaria; (3) intensified preventive disease programs, including expanded cancer control, dental, nutrition and nursing programs; (4) expanded medical research; (5) training of engineers, nurses, technicians and research workers, as well as doctors, to man postwar health armies; (6) health insurance and medical care, as provided in such legislation as the Wagner-Murray-Dingle bill and the Miller bill. Dr. Parran said that 121 bills coming up in the 79th Congress would cover his six point program. "It is a miracle," he said, "that the nation came through the war with no serious health impairment. We suffered no devastating epidemics; tuberculosis was held in check through intensive control efforts, and there was no overall increase in venereal disease."

DANGER OF DISEASE INCREASE IN DEMOBILIZATION

Dr. Parran warns that there is danger of a sharp rise in tuberculosis and venereal disease during demobilization, with millions of war working civilians and servicemen returning to areas where health services and facilities are depleted. "The control of communicable diseases, especially those spread by personal contact," he said, "will be more difficult than during the war, when the military authorities cooperated with the civilian agencies in applying the brakes to spread of infection." Dr. Parran advocated local and state rather than federal control of health problems. The freshman class of eighty-six included twelve women, largest feminine delegation in the history of the university.

Randolph Health Bill for Federal Employees Considered Again

The House Rules Committee has cleared the way for consideration on the House floor of the Randolph health bill for government employees. An hour's debate was ordered. The health bill, sponsored by Representative Jennings Randolph, Democrat of West Virginia, provides for setting up employee health program, including clinics in various government departments, at the direction of department heads. It would be part of a general programs, to promote physical and mental fitness of government employees such as is now carried out by a large number of business organizations.

Presidential Pool Too Deep for Poliomyelitis Patients

Sixty District of Columbia infantile paralysis patients who had hoped to use the White House swimming pool to improve their condition by swimming had the consent of President Truman, but it was found on inspection to be too deep and too small. The pool was formerly used by the late President Roosevelt.

Conference for International Health Organization Advocated by Senator Pepper

Senator Claude Pepper, Democrat of Florida, is pressing for action on his resolution for speedy convening of an international conference to establish a permanent international health organization.

Coming Medical Meetings

American Medical Association House of Delegates, Chicago, Dec. 3-6.
Dr. Olin West, 535 N. Dearborn St., Chicago 10, Secretary.

American Ophthalmological Society, Hot Springs, Va., Nov. 12-14.
Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

Association of American Medical Colleges, Pittsburgh, Oct. 29-31.
Dr. Fred C. Zapffe, 5 S. Wabash Ave., Chicago, Secretary.

Delaware Medical Society of Wilmington, Oct. 8-10. Dr. W. H. Speer, 917 Washington St., Wilmington, Secretary.

Indiana State Medical Association, French Lick, Nov. 6-8. Mr. Thomas A. Hendricks, 23 E. Ohio St., Indianapolis 4, Secretary.

Kentucky State Medical Association, Lexington, Oct. 29-31. Dr. P. E. Blackerby, 620 S. Third St., Louisville, Secretary.

New York Medical Society of the State of House of Delegates, Buffalo, Oct. 8-9. Dr. W. P. Anderton, 292 Madison Ave., New York 17, Secretary.

Omaha Mid-West Clinical Society, Omaha, Nebraska, Oct. 22-26. Dr. R. W. Fouts, 107 S. Seventeenth St., Omaha, Secretary.

Pennsylvania Medical Society of the State of House of Delegates, Philadelphia, Oct. 23-24. Dr. Walter F. Donaldson, 300 Penn Ave., Pittsburgh 22, Secretary.

Southern Medical Association, Cincinnati, Nov. 12-15. Mr. C. P. Loran, Empire Bldg., Birmingham 3, Alabama, Secretary.

Virginia Medical Society of House of Delegates, Roanoke, Oct. 22-23. Miss Aenes V. Edwards, 1200 Clay St., Richmond 19, Secretary.

Official Notes

COMMITTEE ON MEDICAL MOTION PICTURES

The Board of Trustees of the American Medical Association has appointed the following Committee on Medical Motion Pictures to study the problem of production, distribution and use of motion pictures in medical education and graduate medical instruction

Elmer L. Henderson, M.D., Louisville, Ky., chairman of the Committee on Scientific Exhibit, American Medical Association
Morris Fishbein, M.D., Chicago, Editor of THE JOURNAL
A. V. Franzblau, M.D., U.S. Public Health Service, Bethesda, Md.
Thomas S. Jones, Chicago, professor of medical illustration, University of Illinois College of Medicine
Dean F. Smiley, Commander (MC), U.S.N.R., Washington, D.C.
Thomas G. Hull, Ph.D., Chicago, Director of the Scientific Exhibit, American Medical Association

The following consultants have been appointed to assist the committee

Herman L. Kretschmer, M.D., President, American Medical Association
Victor Johnson, M.D., Secretary, Council on Medical Education and Hospitals, American Medical Association
Malcolm T. MacEachern, M.D., associate director, American College of Surgeons
Fred C. Zapffe, M.D., secretary, Association of American Medical Colleges

Council on Medical Service and Public Relations

PREPAID MEDICAL CARE NEWS

New Plan to Include Medical Care in the Home and Doctor's Office

The United Medical Service, Inc., has announced expansion of its program to include a group contract for the provision of medical, surgical and maternity care, including after-care, in the home and doctor's office as well as in the hospital. The expanded service will be limited to a maximum of 25,000 persons enrolled in groups of 50 or more in Associated Hospital Service of New York until further expansion is justified on the basis of actual experience. During the present trial period groups will be selected from widely separated communities in the area covered by the plan. Contracts for the service, which provides full coverage to families with incomes up to \$2,500 and partial coverage for all other enrolled subscribers, will be issued by United Medical Service to employers instead of to individual subscribers as in previous plans. Complete coverage for the expanded service will cost \$1.60 a month for individuals and \$4 a month for husband and wife, including any number of unmarried children under 18 years of age. Subscribers will be entitled to one visit a day from a general practitioner up to as many as twenty visits for any one illness, injury or pregnancy case. Additional visits may be authorized by United Medical Service.

United Medical Service will pay the participating physician \$2 for each visit from a subscriber to his office and \$3 for each visit he makes to the patient at home or in the hospital. For any call after 8 p.m. the physician may make an additional charge, which will not exceed \$2 for subscribers in the lower income brackets. For this group of subscribers such payments will constitute the participating physician's entire fee. Specialist services are provided when the subscriber is referred to a qualified specialist by his attending physician. In these cases United Medical Service will pay the specialist 50 per cent toward an established base rate fee. The specialist will not charge more than the remaining 50 per cent to subscribers with family incomes under \$2,500.

Income limits previously established by United Medical Service for complete benefits are \$1,800 yearly for individuals and \$2,500 for families. Subscribers whose incomes exceed these levels are entitled to partial payments against their bills with the proviso that persons earning between \$2,500 and \$3,500 a year may appeal to a board of physicians and they consider a

doctor's charges too high. It was announced that the contract is being offered to a limited number of subscribers as a test of its feasibility until such time as United Medical Service accumulates sufficient data for actuarial calculations. Contracts will be spread out over as wide an area as possible in order that, with the normal expectancy demand for medical care, no one physician will be likely at the present time to have more than a few subscriber families as patients. The Coordinating Council of the Five County Medical Societies of Greater New York issued a statement approving the project.

Bureau of Information

REPORTS RECEIVED FROM MOST COUNTIES

Twenty-five states have completed and returned summary sheets for all of their counties. Twenty-one additional states have submitted returns from some but not all of the counties in their respective states. Only Delaware, with three counties, Oregon, with thirty-six, and Rhode Island, with five, have not yet returned any summary sheets to the Bureau of Information.

A tabulation of returns from state and county medical societies, as of September 20, is presented herewith.

State	County Returns Complete		
	Number of Counties	Number of Counties Reported	Counties Unreported
Alabama	14	14	0
Arizona	70	70	0
Arkansas	8	8	0
California	1	1	0
Illinois	102	102	0
Indiana	92	92	0
Iowa	99	99	0
Kansas	100	100	0
Kentucky	120	120	0
Louisiana	64	64	0
Maine	16	16	0
Massachusetts	14	14	0
Minnesota	87	87	0
Missouri	110	110	0
Nevada	17	17	0
New Mexico	31	31	0
New York	62	62	0
North Dakota	50	50	0
Ohio	88	88	0
Oklahoma	67	67	0
Oregon	36	95	0
Utah	29	29	0
Vermont	14	14	0
West Virginia	20	20	0
Wisconsin	71	71	0
Total	1,494	1,494	0

Partial Returns of County Summary Sheets

State	County Returns Complete		
	Number of Counties	Number of Counties Reported	Counties Unreported
Alabama	67	65	2
California	28	24	4
Colorado	6	29	1
Florida	67	21	44
Georgia	130	71	59
Idaho	11	27	17
Maryland	4	15	9
Michigan	2	26	27
Mississippi	2	4	2
Montana	3	22	19
Nebraska	9	22	11
New Hampshire	10	8	2
New Jersey	21	9	12
North Carolina	100	37	63
South Carolina	77	61	16
South Dakota	46	25	21
Texas	62	62	0
Virginia	34	16	18
Washington	100	62	38
West Virginia	20	17	3
Wisconsin	71	34	37
Total	1,494	913	601

Since V-J day and even more since V-J day, medical officers or veterans recently separated from service are inquiring with increasing frequency for information which can be obtained from the county summary sheets. In order to supply the requested information, the Bureau must have on file the county summary sheets from all counties in the country. It is urged, therefore, that the states which have not yet returned summary sheets from all their counties do so at the earliest possible opportunity.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

Personal.—Dr. Henry B. Rollins, Hartford, associate medical director since 1931, has been named medical director of the Connecticut Mutual Life Insurance Company to succeed Dr. Charles B. Piper, Hartford, who has been made director emeritus after fourteen years in the position.

Construction of Hartford Hospital to Start Soon.—Approval has been given under a proposed building program given for the immediate construction of the Hartford Hospital, to cost \$6,500,000. The unit will include a new thirteen story main building. The work of clearing the site will start immediately, according to the September state medical journal, and it is hoped that the foundations may be completed before winter.

Medical Advisory Committee for Cancer Society.—The requirement that a majority of the trustees of the Connecticut Cancer Society must be members of the committee on tumor study of the Connecticut State Medical Society was dropped from the by-laws at the recent annual meeting of the society. Instead the cancer society will have a medical advisory committee of seven members, nominated each year by the committee on tumor study to initiate or consider all proposals for the use of the society's funds for medical purposes. Educational activities will be supervised by a public education committee of five members, while a finance committee of five business men will supervise the management of the society's funds. Dr. Abraham N. Creadick, New Haven, was elected president of the cancer society, Ira V. Hiscock, C.P.H., New Haven, vice president, Dr. Joseph O. Collins, Waterbury, secretary and Charles F. Lewis treasurer. Members of the medical advisory committee are Dr. Alfred L. Burgdorf, Hartford, chairman; Dr. Wilmar M. Allen, Hartford; Dr. Howard S. Colwell, New Haven; William U. Gardner, Ph.D., New Haven; Dr. Joseph I. Linde New Haven; Dr. George M. Smith, Pine Orchard, and Dr. Donald B. Wells, Hartford.

ILLINOIS

Personal.—Dr. and Mrs. Charles E. Trovillion, Alton, observed their fiftieth wedding anniversary August 19.—Dr. Edward R. Hays, Omaha, has been elected director of health education for the Evanston schools.

Chicago

Stewart Thomson Returns as Assistant Dean.—Dr. Stewart C. Thomson on September 10 resumed his activities as assistant dean of the Loyola University School of Medicine. Dr. Thomson was recently released from service, after serving for the past seventeen months as chief of the collection branch in the medical intelligence division of the preventive medicine service and as the liaison officer between the Office of the Surgeon General and G-2, War Department General Staff.

Application of Atomic Research to Disease.—An institute to apply the discoveries of atomic research to such problems as cancer, heredity and growing old has been established at the University of Chicago. Raymond E. Zirkle, Ph.D., Springfield, Ill., a botanist who has specialized in the effect of radiations on living organisms, will be in charge of the new department, the institute of radiobiology and biophysics. Members of the new institute will work in cooperation with the institute of nuclear studies. This arrangement is part of the university's plan to further fundamental research in fields which were kept secret or neglected during the war.

Lying-In Hospital Observes Fiftieth Anniversary.—A special program will be held October 29 at the Chicago Lying-In Hospital to observe the fiftieth anniversary of its founding. The hospital was established in 1895 by Dr. Joseph B. De Lee. In addition to clinics being conducted by members of the staff, the following will participate:

Dr. Frederick C. Irving, Boston, A Blood Bank for a Lying-In Hospital.
Dr. Edwin C. Hamblen, Durham, N. C., Some Contributions of Endocrinology to Obstetrics and Gynecology.
Dr. Norman F. Miller, Ann Arbor, Mich., Hysterectomy—Therapeutic Necessity or Surgical Racket?
Dr. Henricus J. Stander, New York, Teaching of Obstetrics and Gynecology.

KANSAS

Personal.—Dr. Thomas E. Johnston has resigned as medical director of the Security Benefit Association, Topeka, to become gynecologic surgeon for the Dr. Robert H. Adams clinic, Oklahoma City.—Dr. Grant R. Hastings, Garden City, has been named a member of the Kansas State Board of Health by Governor Andrew Schoeppel. Dr. Hastings will fill the unexpired term of Dr. John L. Lattimore, Topeka, ending in March 1946, resigned (*THE JOURNAL*, March 24, p. 723).

Changes at University.—Dr. Joseph E. Welker, associate professor of medicine, University of Kansas School of Medicine, Kansas City, has been appointed clinical professor. Drs. Don C. Peete, Arthur Graham Asher and Orval R. Withers, all of Kansas City, Mo., have been advanced to associate professorships in medicine and Dr. Albert T. Steegmann to associate professor in psychiatry. Dr. Benjamin L. Elliott, Kansas City, Mo., has been promoted to assistant professor of psychiatry.

Members of Health Education Council.—Dr. Ralph I. Canuteson, Lawrence, representing medicine, L. W. Brooks, Topeka, the state superintendent of education, and Dr. Floyd C. Beelman, Topeka, executive director of the state board of health, have been named as members of the Kansas Health Education Council to direct a statewide school health study (*THE JOURNAL*, March 24, p. 723 and July 21, p. 892). An advisory committee of some twenty members is to be named, the appointments to be made probably sometime in the fall, when more definite steps are expected to be adopted for pursuing the program.

KENTUCKY

Field Director of County Health Work.—Dr. Ralph Gregg, senior surgeon, U. S. Public Health Service, has been assigned to the Kentucky State Health Department to serve as field director in the division of county health work. Dr. Gregg, who recently returned from London, was formerly liaison officer to the Fifth Service Command headquarters at Columbus, Ohio.

MICHIGAN

Courses in Public Health.—The University of Michigan School of Public Health, Ann Arbor, is announcing an inservice training course in environmental controls for industrial processes October 2-4, with special reference to metal working industries. Another course will be held October 8-11 on public relations, staff education and community health education for health directors. Additional information may be obtained from the School of Public Health Building, 109 South Observatory Street, Ann Arbor.

Physician Wins Reversal of Sentence.—Dr. Fred W. Thomas, Detroit, on September 17 won reversal of a sixteen year sentence imposed in 1944 in Detroit on a charge of conspiring to violate the wartime espionage act (*THE JOURNAL*, July 8, 1944, p. 729). The sixth circuit court of appeals, meeting in Cincinnati, citing error in a charge delivered by District Judge Edward J. Moinet, ordered retrial of the case, newspapers reported. The opinion reversing the original decision set forth that although Dr. Thomas was charged with "conspiracy" to violate the act, Judge Moinet had told the jury he was charged with violation of the statute. The physician was accused of supplying Germany with espionage information of war production and troop movements.

MINNESOTA

Award to Civilian for Service to Army Air Forces.—In recognition of his contribution to the Army Air Forces and the nation's war effort, Edward J. Baldes, Ph.D., Rochester, recently received the army's highest award that is available to civilians, according to the *Clinic Bulletin*. The citation accompanying the ribbon was signed by Secretary of War Henry L. Stimson and was presented at an outdoor ceremony in front of the Aero Medical Laboratory at Wright Field, Dayton, Ohio, by Brig. Gen. L. C. Craige, chief of the engineering division of the Air Technical Service Command. The citation was given in recognition of his work in the design of special centrifuge devices. His exceptional ability and outstanding service have contributed immeasurably to the flying safety of American aviators and provided the Army Air Forces with the finest scientific knowledge available.

NEW YORK

James McCartney Opens Neuropsychiatric Clinic.—Dr. James L. McCartney is opening a clinic in Garden City, where he will place special emphasis on the neuropsychiatric problems of returned officers and their families. Dr. McCartney, who was released from active duty in the Navy September 10, was serving as chief of the neuropsychiatric department of a naval base hospital in the Marianas Islands.

Memorial at Buffalo Hospital.—A total of \$98,700 was subscribed to the building fund of Buffalo General Hospital, Buffalo, by Spencer Kellogg and Sons and Mr. and Mrs. Howard Kellogg Sr. Of the total gift, \$67,500 is to be used to build, furnish and equip an intern's laboratory, basal metabolism department and a chemistry lecture room on the second floor of the hospital, all to be dedicated to the memory of Spencer Kellogg, founder of the company. Two nurseries on the tenth floor will be established with the \$24,000 gift of Mr. and Mrs. Kellogg, also to be memorials to relatives of the Kellogg family. The remainder of the gift will be used to dedicate a 4 bed room in memory of members of the family.

Mental Hygiene Lectures.—"The Mental Hygiene of Personal Counseling" will be the theme of an institute at the Hotel Onondaga, Syracuse, beginning September 24. The course is designed for physicians and interested lay persons and includes:

- Lawrence K. Frank, director, Fochy Institute, New York, Mental Hygiene Aspects of Family and Social Life, September 24
- Dr. Evie E. Welsh, director, Child Guidance Center, Rochester, Mental Hygiene Aspects of Growing Up, October 1
- Luther E. Woodward, Ph.D., field consultant, National Mental Hygiene Committee, New York, Interviewing and Counseling Methods, October 8
- Dr. Helen Flanders Dunbar, director of psychosomatic research, Presbyterian Hospital, New York, Psychosomatic Reactions in Interpersonal Relations, October 17
- Dr. Matthew Brody, consulting psychiatrist, Sperry Gyroscope Company, Brooklyn, Industrial Psychiatry, October 22
- Dr. George K. Pratt, psychiatrist, Westport, Conn., Personality and Emotional Disorders, October 29
- Dr. Edward A. Strecker, professor of psychiatry, University of Pennsylvania School of Medicine, Philadelphia, Alcoholism, November 5

Seminars on Rheumatic Fever and Rheumatic Heart Disease.—The St. Francis Sanatorium for Cardiac Children, Roslyn, announces a course of seminars on rheumatic fever and rheumatic heart disease Tuesday and Thursday of each week beginning October 2 and ending November 1. The course will cover epidemiology, prevalence, etiology and immunology; pathology; clinical course of disease; laboratory aids in diagnosis; public health aspects and care and management. The faculty will be:

- Dr. Cary Eggleston, associate professor of clinical medicine, Cornell University Medical College, and New York Hospital, New York
- Dr. Oswald Lenton Hedley, surgeon, U. S. Public Health Service
- Dr. Thomas Duckett Jones, assistant professor of medicine, Harvard Medical School, Boston, House of Good Samaritan
- Dr. John Rollman Paul, professor of preventive medicine, Yale University School of Medicine, New Haven, Conn.
- Dr. Homer Lordyce Swift, Hospital of the Rockefeller Institute of Medical Research, New York
- Dr. Leo M. Taran, medical director, St. Francis Sanatorium for Cardiac Children, Roslyn
- Dr. William Carson Von Glinn, director of pathology at Bellevue Hospital and professor of pathology at New York University College of Medicine
- Dr. Max Georgiana Wilson, associate professor of clinical pediatrics, Cornell University Medical College and New York Hospital

New York City

Personal.—Dr. William A. Boyd recently observed his fiftieth year in the practice of medicine. Dr. Boyd was the first vice president of the Bronx County Medical Society when it was chartered. He was one of the organizers of the Bronx Medical Association, serving as its president in 1910 and later as treasurer.

Brooklyn Cancer Committee.—The Brooklyn Cancer Committee was recently organized, with Dr. Samuel Potter Bartley as chairman, to carry out a comprehensive lay program of education on cancer control. Dr. Bartley is chairman also of the cancer committee of the Medical Society of the County of Kings. An advisory council has been set up consisting of thirty-two Brooklyn physicians.

Special Committee on Psychosomatic Medicine.—The Medical Society of the County of New York has created a special committee on psychosomatic medicine to be composed of Drs. Carl A. L. Binger, chairman, Harold G. Wolff, Edwin G. Zahrbick and George E. Daniels. While a general program has not yet been formulated, the new committee will probably aid physicians in general practice in meeting psychosomatic problems encountered in their daily work.

Dean Clark Named Medical Director of La Guardia's Health Plan.—Dr. Dean A. Clark, assistant director, public health methods division, senior surgeon, U. S. Public Health Service, has been granted a leave to become medical director of the Health Insurance Plan of Greater New York, the health insurance project sponsored by Mayor Fiorello La Guardia (THE JOURNAL, Nov. 4, 1944, p. 648). Dr. Clark took up his new activities August 1, according to *New York Medicine*.

Adolf Magnus-Levy Honored.—On September 10 a reception was held at Sherry's to honor Dr. Adolf Magnus-Levy on his eightieth birthday. Dr. Magnus-Levy, who came to the United States from Germany about four years ago, is known for his researches in metabolism and on acidosis. Dr. Emanuel Libman gave the introductory address, and other speakers included Dr. Eugene F. Du Bois, professor of physiology, Cornell University Medical College, and Dr. Kurt M. Grassheim, a pupil of Dr. Magnus-Levy. Dr. Magnus-Levy joined the staff of Yale University, New Haven, Conn., in 1941 as research associate in physiology.

Friday Afternoon Lecture Series.—The twentieth series of Friday Afternoon Lectures of the New York Academy of Medicine starts as follows:

- Dr. Hattie Elizabeth Alexander, Treatment of Influenza Bacillus Infections in Childhood, November 2
- Dr. Edward Tolstoi, Diabetes, Newer Aspects of Management, November 9
- Dr. John R. Paul, New Haven, Conn., Infectious Hepatitis (A. Walter - Suiter Lecture under auspices of the committee on public health relations), November 16
- Dr. Cary Eggleston, Newer Chemotherapeutic Agents, November 30
- Dr. William Dock, Senescence of the Myocardium—Presbycardia, December 7
- Dr. Arthur C. DeGraff, The Therapeutic and Toxic Actions of Some Drugs Recently Introduced in the Treatment of Cardiac Disorders, December 14
- Dr. Ralph L. Barrett, Hemorrhages in the Viable Period of Pregnancy, December 21

OHIO

Personal.—Dr. Arda Alden Green, formerly assistant professor of biochemistry in the Washington University School of Medicine, St. Louis, is now associated with the research division of the Cleveland Clinic. Dr. Green's latest important contribution has been the successful crystallization of phosphorylase from muscle. She will continue biochemical investigation in connection with vascular disease.—Dr. C. Herbert Cronick has resigned as medical director of the Youngstown Receiving Hospital for Mental Cases; the hospital was recently leased by the state department of public welfare (THE JOURNAL, January 6, p. 46).

Cincinnati Academy Opens Scientific Season.—The annual meeting of the Academy of Medicine of Cincinnati was held September 18 and marked the opening of the academy's program for the coming year. Among the speakers at the forthcoming sessions will be:

- Dr. Marion A. Blankenhorn, Cincinnati, October 2, Persistent Problems of Pneumonia
- Dr. George A. Schwemlein, Chicago, October 16, The Present Status of Penicillin in the Therapy of Syphilis
- Dr. Jerome W. Conn, Ann Arbor, Mich., November 6, Some Problems Related to Insulin Action
- Dr. George T. Pack, New York, November 20, The Extension of Radical Surgery in the Treatment of Cancer
- Dr. Jules H. Masserman, Chicago, December 4, Experimental Approach to the Understanding of Neurotic Symptoms

PENNSYLVANIA

District Meeting.—The annual meeting of the Second Councilor District of the Medical Society of the State of Pennsylvania was held September 5 in Lancaster. Speakers included:

- Dr. William Bates, president, state medical society, Philadelphia, The Activities of the State Medical Society
- Dr. Chumcey L. Palmer, Pittsburgh, Comments on Proposed Social Legislation
- Dr. Chevalier L. Jackson, Philadelphia, Current Trends in the Diagnosis and Treatment of Bronchial Disease

Fifty year testimonials will be presented to the following by Dr. Walter F. Donaldson, Pittsburgh, secretary of the state medical society:

- Dr. Irvin H. Hartman, Reading
- Dr. Samuel Banks Taylor, Reading
- Dr. Leroy Y. Lechner, Bechtelsville
- Dr. Henry A. Rothrock, West Chester
- Dr. Mary McD. Shick, Elwyn
- Dr. Thomas E. Wills, Pottstown

The county medical societies of Berks, Bucks, Chester, Delaware, Lehigh and Montgomery compose the Second Councilor District.

Philadelphia

Industrial Health Problems.—The industrial hygiene bureau of the Pennsylvania Department of Health sponsored a conference on industrial health problems at the Benjamin Franklin Hotel, September 25-26. Among the speakers were:

- Lyman D. Heacock, senior dental surgeon, U. S. Public Health Service Reserve, Prevention of Oral Diseases of Occupational Origin.
- Dr. Louis Schwartz, medical director, U. S. Public Health Service, Prevention of Industrial Dermatoses.
- Dr. Charles Francis Long, Philadelphia, Illness in Industry.
- Dr. Glenn S. Everts, Philadelphia, Industrial Health in Small Plants.
- Dr. Harvey Bartle, Philadelphia, Medical Criteria in the Reconversion Program.
- Mr. J. J. Bloomfield, senior sanitary engineer, U. S. Public Health Service, Integration of Industrial Health in the Public Health Program.
- Dr. Victor G. Heiser, New York, Value of Industrial Health to Management.
- Dr. Leonard A. Kagen and Mr. E. L. Schall, industrial hygienist, Trenton, N. J., Environmental Conditions in Plants Molding Lead Plastic Bullets.
- Dr. C. Charles Burlingame, Hartford, Conn., Mental Health in Industry.
- Dr. Charles F. Kutscher, Pittsburgh, Industrial Ophthalmology.

WASHINGTON

Tuberculosis Building Commission.—The last legislature appropriated a three million dollar fund to construct tuberculosis institutions in Washington and provided for the creation of a state tuberculosis building commission. Members of the commission named by Governor Wallgren include Tom Jones Parry, Seattle, advertising executive; Dr. Ottar A. Thomle, Everett; Louis Schaefer, Vancouver, attorney; Lloyd L. Wiehl, Yakima, county prosecutor; Ab Ruhl, Spokane, union executive, and Arthur H. Brouse, Tacoma, bank executive.

State Health Department Activities.—Dr. S. Harvard Kaufman, formerly psychiatric consultant with the Children's Aid Society and Children's Service Bureau in Pittsburgh, has been appointed director of the mental hygiene section of the Washington State Department of Health. The section was transferred from the division of local health services to the division of preventive medical services and constitutes a continuance of reorganization of the state department of health (THE JOURNAL, February 3, p. 288). Dr. George C. Stevens, who was head of the mental hygiene section when it was created, has resigned to engage in private practice in Seattle. The reorganization includes the establishment of a division of public health nursing with Anna R. Moore, R.N., chief, a venereal disease control section with Dr. Walvin R. Giedt as acting head and an epidemiology section with Dr. Giedt as head. Both of these sections are in the division of preventive medical services, and the public health nursing division was formerly a section under the division of local health services and the venereal disease control and epidemiology sections formerly were a part of the communicable disease control section. The state department of health announces the issuance of a new stillbirth certificate to be used in the state as authorized by the last session of the legislature. Under the new definition, all births occurring without evidence of life after the twentieth week of gestation will be regarded as stillbirths. This is in contrast to the seven month figure as given in the old law. After September 1, only the new certificate will be acceptable for filing a stillbirth.

WEST VIRGINIA

Personal.—Major Michael G. Hresan, M. C., Minden, is serving as physician to Arthur Bliss Lane, American ambassador to Poland, and the members of his staff, at Warsaw. According to a letter received by the West Virginia State Medical Association from Major Hresan, he is the first American officer to be stationed in Warsaw since 1939.

WISCONSIN

\$25,000 for Cancer Research.—The governor recently signed a bill appropriating \$25,000 annually "for study of and research into the causes, prevention and cure of cancer and for the purchase of necessary apparatus and supplies for the purpose of carrying on such study and research." The appropriation was earmarked for July 1.

Albert Edwards Named Health Officer of Racine.—Dr. Albert C. Edwards, Port Huron, Mich., director of the St. Clair County health department, has been named health officer of Racine, to succeed Dr. Ira F. Thompson, who resigned (THE JOURNAL, June 30, p. 678). Dr. Edwards graduated at the University of Nebraska College of Medicine, Omaha, in 1925. He was formerly employed by the Wisconsin State Board of Health and at one time served as director of the district health department number 5 at White Cloud, Mich.

GENERAL

Export and Import of Narcotic Drugs.—The Bureau of Narcotics, U. S. Treasury, on August 24 released a statement concerning the granting of permits to import or export narcotic drugs. Additional information may be obtained from the Bureau of Narcotics, Washington 25.

Ambulatory Fracture Meeting.—The Ambulatory Fracture Association will hold its sixth annual meeting in the Club Building at the Palmer House, Chicago, October 26-27. The meeting will be continued in Bloomington, Ill., October 29-30, where operative clinics and clinical conferences will be held. Dr. Alvin H. Diehr, St. Louis, is president of the association and Dr. Hermann W. Wellmerling, Bloomington, secretary-treasurer.

National Employ the Physically Handicapped Week.—President Truman on August 11 signed a bill which sets apart the first week in October of each year as National Employ the Physically Handicapped Week. The observance was set up in H. J. Res. 23 and is now Public Law 176. Appropriate ceremonies are to be held throughout the nation to enlist public support for an interest in the employment of otherwise qualified but physically handicapped workers.

French Radiologists Ask for Reprints.—Radiologists in France have appealed to radiologists in the United States to send them reprints from 1939 of their articles concerning radiology (diagnostic), roentgen therapy, radium therapy and neutron therapy, electrodosimetry and cancerology. The appeal was written to Dr. Ursus V. Portmann, Cleveland, by Dr. Robert Coliez, president of the Hospital Radiologists of Paris, who requests that reprints should be addressed to him at 25, Rue Franklin, Paris, XVIème.

Biologists Urge Educational Program on Experimental Work.—The Pacific Coast Section of the Society for Experimental Biology and Medicine recently passed a resolution endorsing the creation of a bureau of public relations to educate the public concerning current legislation and campaigns to limit biologic experimentation. One resolution stated that the section deplored "the campaign being waged at this time to limit biological experimentation by means of antivivisection legislation in state and in national legislatures."

Association of Military Surgeons.—The Association of Military Surgeons of the United States will hold its next annual session in Detroit Oct. 9-11, 1946. The 1945 meeting was deferred. Any correspondence relative to the scientific program should be addressed to Dr. William D. Ryan, 5837 West Vernor Highway, Detroit 4, and any correspondence relative to the commercial exhibits should be addressed to Mr. Steven K. Herlitz, 280 Madison Avenue, New York 16. Major Carleton Fox, Dental Reserve, U. S. Army, is the general chairman, 557 David Whitney Building, Detroit 26.

Examination in Obstetrics and Gynecology.—The next written examination and review of case histories (Part I) for all candidates will be held in various cities of the United States and Canada on Saturday, February 2. Candidates who successfully complete the Part I examination proceed automatically to the Part II examination held later in the year. All applications must be in the office of the secretary of the American Board of Obstetrics and Gynecology by November 1. All candidates are now required to be out of medical school eight years, and in that time they must have completed an approved one year internship and at least three years of approved special formal training, or its equivalent by the preceptorship method under a recognized obstetrician-gynecologist or a specialist certified by this board, in the seven years following the intern year. Additional information may be obtained from the secretary, Dr. Paul Titus, 1015 Highland Building, Pittsburgh 6.

Insurance Company Launches Campaign Against Cancer.—The Metropolitan Life Insurance Company will conduct a special campaign for the control of cancer during October. The program will include the distribution to practicing physicians of a special packet of new information on cancer, including the booklet of the American Cancer Society entitled "The General Practitioner and the Cancer Patient," a reprint of recent studies of cancer mortality prepared by the company's statisticians; a reproduction of the company's educational advertisement "Cancer Has Its Hopeful Side!" and a copy of the company's new leaflet for laymen "There is Something You Can Do About Cancer." According to an announcement from Metropolitan, in the past decade the age adjusted death rate from cancer insured white females dropped 11 percent at ages 1 to 74. The current mortality from the disease among women in the broad age range 35 to 64 is the lowest

in a third of a century, having dropped by one fifth during that period. Among white male policyholders, during the past decade, at no age beyond 25 years has the cancer death rate shown any increase.

Thomas Gentry Named Medical Director of American Airlines.—Col. Thomas C. Gentry, surgeon, 14th Air Force, M. C., United States Army, has been appointed medical director of the American Airlines, Inc., effective September 1. He succeeds Lieut. Col. Edward C. Greene, M. C., U. S. Army, retired. Following his graduation at Baylor University College of Medicine, formerly of Dallas and now of Houston, Dr. Gentry entered the army medical corps as an intern and in 1931 he graduated from the School of Aviation Medicine as a flight surgeon. In 1934 he resigned his army commission to enter private practice at Hamlin, Texas. He reentered the army as a reserve officer in 1935. In 1941 he gave up his commission to organize the medical service of the original Flying Tigers, going to China as chief surgeon of the American Volunteer Group, the original Flying Tigers. When the American Volunteer Group became part of the U. S. Army Air Force in June 1942, Colonel Gentry continued working under Gen. Claire L. Chennault, founder of the Flying Tigers and commanding general of the succeeding China Air Task Force and the 14th Air Force.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended September 15 have been received from the division of public health methods, U. S. Public Health Service, as follows:

	Week Ended Sept. 15, 1945	Week Ended Sept. 16, 1944		Week Ended Sept. 15, 1945	Week Ended Sept. 16, 1944

LATIN AMERICA

Health Activities in Latin America.—*Merchant Marine Dispensary.*—On July 2 a dispensary for merchant seamen to be known as the Merchant Marine Dispensary was opened under the auspices of the Panama Canal Health Department and the War Shipping Administration. The unit will ease the pressure on the Colon Hospital, Cristobal, C. Z., which has been caring for seamen. The services at the clinic will be in charge of a staff consisting of two health department physicians, two U. S. Public Health Service dentists, one psychiatrist and two pharmacist's mates.

Pan American League for Study and Control of Rheumatic Diseases.—The establishment of a Pan American League for the Study and Control of Rheumatic Diseases was recently announced. Representatives include Argentina, Brazil, Canada, Chile, Mexico, Paraguay, Peru, Uruguay and the United States. Officers are Drs. Ralph Pemberton, Philadelphia, president; Anibal Ruiz-Moreno, Buenos Aires, vice president; Loring T. Swaim, Boston, secretary, and Fernando Herrera Ramos, Montevideo, Uruguay, treasurer. The objectives of the league are to strengthen the cultural bonds between the countries of North and South America, to further efforts to alleviate suffering from rheumatic diseases and to institute measures of prevention, to compile and disseminate knowledge and information regarding rheumatism in the respective countries, to unify the nomenclature and classifications, to promote scientific investigation and to hold Pan American congresses on the

rheumatic diseases. The idea to create the league had its origin with Dr. Ruiz-Moreno and his colleagues in Buenos Aires. Indirectly it stemmed from the Ligue internationale contre le rhumatisme. The original prospectus of the Pan American League expressly set forth that it is in no sense meant to act as a substitute for the Ligue internationale but rather as an amplification and implementation of the older league's purposes.

Latin Americans Assist in UNRRA Program.—Eight doctors from Colombia and five from Venezuela have come to UNRRA to work on its program of medical and health assistance now carried on in the liberated areas of Europe. The doctors are at present at the UNRRA training center at the University of Maryland, where they are taking a two weeks orientation course before leaving for overseas. From Colombia are Drs. Hector Acevedo, Bogota; Gustavo Gomez-Hurtado, Bogota; Alfonso Gomez, Bogota; Jorge Jimenez, Bogota; Ganzalo Montes, Bogota; Gerardo Paz, Popayan; Carlos Quintero Hernandez, Barranquilla, and Alvaro Ujueta, Bogota. From Venezuela are Drs. Imelda Campo, Caracas; Victor Estaba Acuna, Caracas; Juan Alberto Gambus, Maiquetia; Francisco Emilio Rodriguez, Barquisimeto, and Claudio G. Vargas Mendoza, Tovar Estado Merida. The Colombians and Venezuelans are the fourth group of doctors to come to UNRRA for European service. Nine Cuban doctors left last week for overseas, eleven Mexican doctors are now at the training center and Brazil is sending a group directly to Reading, England. The doctors will be part of the 450 teams working at displaced persons assembly centers, where the millions of people who have been uprooted from their homes by Nazi aggression are given every possible aid in returning to their own countries as quickly as possible.

FOREIGN

Nuffield Foundation.—The central office of the Nuffield Foundation and Nuffield Provincial Hospitals Trust is now at 12-13 Mecklenburgh Square, London, W. C. 1, according to the *Lancet*. Mr. L. Farrer-Brown has taken up his duties as secretary of both organizations.

Cancer Research Fund.—A gift of £10,000 to the Sheffield Radium Center to create a fund for research in radiotherapy of cancer has been made by Mr. James Morrison, accountant and estate agent. The fund has been named after his brother David, in whose memory it has been founded, and it will be used to establish a research department at the center for the study of new methods of irradiation, according to the *Lancet*. Supervoltage x-ray equipment and a radium-beam unit are to be installed. The trustees of the fund, nominated by Mr. Morrison, are Dr. Charles Sydney Atkin, Dr. George W. Bloomfield, medical director of the center, and Mr. F. M. Osborn, deputy chairman of the Royal Sheffield Infirmary and Hospital.

Physicians in Parliament.—With the recent election of Sir John B. Orr as one of the members for the Scottish universities, the total number of physicians who will sit in the new parliament is fourteen. Sir John is director of the Rowett Research Institute and the Imperial Bureau of Animal Nutrition. The following were members of the last parliament: Drs. Leslie Haden Guest, H. B. W. Morgan, Sir John Henry Morris-Jones, Basil H. H. Neven-Spence, Sir Ernest G. Graham-Little and Edith C. Summerskill. Dr. Somerville Hastings returns after an interlude of local government. Others are Drs. Louis Comyns, Santo W. Jeger, Samuel Segal, Malcolm Stoddart-Scott, Barnet Stross and Stephen J. L. Taylor.

Rockefeller Foundation Offers Fellowships in Public Health.—The Rockefeller Foundation is offering a small number of fellowships to medical men and women of British birth who wish to take up public health as a career. The fellowships will usually be awarded for two years, and their annual value will be between £450 and £800. Traveling expenses will be paid during residence abroad. Candidates will be expected to have had some general clinical experience since registration, and service in the forces will be taken into account. Normally a fellow will be asked to spend not less than a year studying preventive medicine at the London School of Hygiene, when he will be given an opportunity to take the qualifying course for the DPH. He will also be expected to take part in teaching, to undertake a study or investigation approved by the committee of award and to work at institutions abroad during at least part of his tenure of the fellowship. No forms of application will be issued, but candidates should write informally to the dean of the London School of Hygiene, Keppel Street, London, W. C. 1.

Foreign Letters

LONDON

(From Our Regular Correspondent)

Sept. 1, 1945.

The Socialist Government in Conflict with the British Medical Association

In the House of Commons a member of the government, Mr. Greenwood, made an attack on the minister of health of the late government, Mr. Willink, and charged him with opening discussions on the plan for a national health service with the British Medical Association behind the back of every one else. Mr. Willink pointed out that Mr. Tom Johnson, a member of the Labor party, had been associated with him in these discussions. Mr. Greenwood said that the present government would not start where these negotiations had finished. It must go back to the white paper, and its task would be more difficult because of the unnecessary concessions which Mr. Willink had made. In the House of Lords another member of the government, Lord Addison (formerly a professor of anatomy), said that there would be departures from decisions which Mr. Willink seemed to have reached *in camera* with various parties. In a later debate Mr. Willink pointed out that the discussions were not only, or even primarily, with the British Medical Association: they were with the local authorities, the voluntary hospitals and with a body representative of the whole medical profession—the Royal Colleges, the health officers and the general practitioners. The British Medical Association representatives made about half of one of those three bodies. There were of course other discussions with pharmacists, dentists and other bodies. The local authorities disliked the proposal to transfer their hospitals to the joint boards. Both the voluntary hospitals and the medical profession claimed a fuller share in the planning of the future hospital and other services than was accorded to them in the white paper. The best opinion, both lay and medical, was unanimous that the scheme gave no adequate place to the influence which the universities with medical schools should be able to bring to bear on the planning and development of the hospital and health services. The voluntary hospitals and the doctors were apprehensive as to local authority control of their work. The general practitioners were among many who objected strongly to the powers proposed to be entrusted to a central medical board. By the end of May the negotiations had reached a stage where, without loss of a single service contemplated in the white paper, a structure had emerged likely to command such general agreement as was possible.

In a letter to the *Times*, Mr. Souttar, president of the British Medical Association, who has been concerned in the negotiations from the start, says that to accuse Mr. Willink of having made unjustifiable concessions to the medical profession is a complete misrepresentation. But for the election the discussions would have been published long ago. Mr. Souttar thinks that the negotiators convinced both Mr. Willink and his expert advisers that the proposals originally drafted were unworkable and not in the public interest. Speaking for the whole medical profession, he says that their one ambition is that the best possible service should be available to every member of the community. Whether any of the things agreed on will be accepted by the socialist government cannot yet be said, but it is recognized in the profession that the change of government is most detrimental to the hopes entertained of a satisfactory agreement.

Slight Fall in the Birth Rate

The wartime upward movement of the birth rate, which has been recorded from time to time in *THE JOURNAL*, was arrested in the first quarter of this year and showed a slight fall compared with the corresponding quarter of last year—a rate of

17 per thousand of population compared with 17.4. The rate was still well above the average of the five preceding first quarters, which was 15.2. The provisional infant mortality was 59 per thousand live births, 11 below the average of the ten preceding first quarters. The death rate was 15.1 per thousand, compared with 13.8 for the same quarter a year ago and an average of 16.0 for the corresponding quarters in the previous five years. Thus the improved vital statistics of the war period, reported previously in *THE JOURNAL*, have been maintained.

PARIS

(From Our Regular Correspondent)

Sept. 3, 1945.

Social Security Plan

At the last meeting of the *Assemblée consultative* the government presented for discussion a plan of social security in France. The French plan had to take into consideration the multiplicity of the existing social security organizations. There are nearly 900 social insurance funds, many of them private, and 23,000 mutual societies with 5½ million members. Fifty per cent of all these "funds" are organized on a district basis, 20 per cent are mutual, 10 per cent professional, 12 per cent Catholic and 8 per cent trade unionist. All these funds work independently of one another, their organization often overlapping. The method of contribution is complicated, as well as the payment allowances. The insured persons are often visited, for checking purpose, by three or four social workers of different funds. The general expenses of these funds amount to 10 to 12 per cent, and those of the industrial accident insurances even up to 30 per cent of the amount of the premiums. The present industrial accident insurance system, which is based on the law of 1898, is inefficient because the insurance is facultative. The family allowance funds are exclusively under the employers' direction.

The new plan proposes the regrouping of the insurance system on the general basis of compulsory mutual assistance, the type of which is indicated by the existing social insurance organizations. A single local social security fund is planned for all social risks: disease, maternity, death, industrial accidents, industrial sickness and family allowance. There will be only one contribution covering all social risks.

The administration of the new organization will present the following features:

1. The single local fund will be operated (based on the mutuality law) by a council composed of two thirds representatives of the insured persons (appointed by the trade unions) and of one third representatives of the employers and the staff of former funds and by two physicians designated by the council on proposal of the medical organization.
2. The district security council will be created to coordinate the work of the local funds and to look after the sickness claims. They will direct the medical control and the sanitary and social activity of all the funds assigned to their district. Only the district fund will be allowed to organize a social service. The district fund will be operated by the council, which will be constituted in the same way as the local funds.
3. A national social security fund will be organized which will direct the work of the national territory, as well as a superior council at the Ministry of Labor.
4. Taking into consideration the urgent repopulation problem of France, a superior committee for family allowances will be created.

THE ADVANTAGES OF THE NEW SYSTEM

The insured person will find in the vicinity of his home the service to which he has to apply. The task of the employers and of the administrative services will be considerably simplified by the single contribution paid to the local fund. In consequence of this reorganization a reduction in the number of the

funds to 200 is foreseen. Owing to the simplification of the organizations spoken of, 700 million francs will be saved yearly out of a total contribution estimated at 75 billions for 1945 and more than 100 billions for 1946. This coordination will allow organization of a preventive system of industrial accidents and sickness, which is insufficiently developed in France. All this will also contribute to the campaign against social diseases. At the same time the coordination of medical organization, fee rates, drug and hospital costs and medical checkup will be facilitated.

For the time being, the social security plan is limited to the reorganization of the existing system to make it the starting point of a larger plan tending to extend social security to all classes of the population, first of all to the workers and the middle classes. The plan submitted to the Assemblée consultative already involves all salaried persons in social insurance, independently of their age and even if they are pensioners or if they work for one or several employers. The Minister of Labor reported that another elaborate plan was ready for the complete reorganization of old age insurance, and for the institution of a special method of indemnification and care of chronic diseases such as tuberculosis.

Buenos Aires

(From Our Regular Correspondent)

Aug. 2, 1945.

Alloxan and Tolerance to Dextrose in Rats

Drs. V. G. Foglia, O. Orias and J. Sara recently read a paper before the Argentine Society of Biology. They had performed experiments on rats either normal or pancreatectomized, placed in different lots of six rats each. Pancreatectomized rats had only 5 per cent of the pancreas. Pancreatectomy was performed one or two months before the experiment. The animals were kept fasting for fifteen hours before the experiment. Dextrose was administered by means of a gastric sound in a dose of 3 Gm. for each kilogram of body weight. Alloxan was intraperitoneally injected in a dose of 150 mg. for each kilogram of body weight. Dextrose produced transient hyperglycemia, which was more apparent in pancreatectomized rats than in normal rats. Alloxan produced moderate hyperglycemia in both normal and pancreatectomized rats. Hyperglycemia lasted for three to five hours and was followed by acute hypoglycemia. Dextrose and alloxan when given together produced subacute hyperglycemia of long duration in both normal and pancreatectomized rats, with a higher peak and longer duration in those pancreatectomized. Hypoglycemia did not follow. The animals in the two lots which had had an intraperitoneal injection of alloxan had a second injection one month after administration of the first injection. The second injection produced, very late, a transient mild hyperglycemia which was milder in the pancreatectomized rats. Hypoglycemia did not result. The administration of dextrose to pancreatectomized rats which had subdiabetogenic doses of alloxan after pancreatectomy produced hyperglycemia which was more acute and of longer duration than that which occurred in pancreatectomized rats which did not have alloxan after pancreatectomy.

Reunion of Medical Society

The Asociación Médica Argentina held its annual meeting during the third week of November 1944 in Santa Fe. The attendance was large. Delegates from Uruguay were present. There were the surgical sessions and three scientific sessions. The following topics were discussed: the diagnostic problem of meningitis with clear cerebrospinal fluid, by Dr. Juan Carlos Plá of Montevideo; rational nonbleeding therapy of the inextinguishable nontuberculous lung, by Drs. Mariano R. Castex and Eduardo Luis Capdehourat; experimental diabetes: its contribution to the progress of medicine, by Dr. Bernardo A. Houssay; the importance of bronchoscopy in tuberculosis, by Dr. Justo

Brief Items

Dr. Alois Bachmann, professor of microbiology of the Faculty of Medicine of the University of Buenos Aires, recently retired on account of having reached the limit of age for teaching. Dr. Ruperto Quiroga was appointed to the chair.

Dr. Manuel A. Viera of Buenos Aires was recently appointed general director of public health in the position rendered vacant through the resignation of Dr. Eugenio Galli.

A medicosurgical week was observed in the Britannic Hospital of Buenos Aires in October 1944 to celebrate the centenary of the founding of the hospital.

The representative of the Britannic Council of London in Latin America recently delivered a new equipment for anesthesia to Dr. Alberto Gutiérrez. It is a donation of Dr. R. R. Mackintosh, professor of anesthesiology of the University of Oxford, to the Faculty of Medicine of Buenos Aires.

An institute of aeronautical medicine was recently opened in the National School of Aeronautics in Buenos Aires. It offers a postgraduate course for physicians covering seven consecutive months.

Deaths

Dr. Pío del Río Hortega, Spanish histologist of the nervous system and disciple of Ramon y Cajal, died in Buenos Aires on June 1, where he had lived for several years to preserve his democratic ideals. He founded a laboratory and a school in which he worked and taught constantly. Dr. del Río Hortega discovered the microglia and its physiologic and pathologic meaning in 1919; later on he discovered the aligodengroglia and the neuroglia. His work on the neuroglia of the nerves and its ends, on tumors of the nervous system, on the structure of the pineal body and on many other histologic aspects of the nervous system are well known.

Dr. Kallas, professor of physiology of the Faculty of Medicine of the University of Concepción, Chile, died recently.

Marriages

MILTON THOMAS EDGERTON JR., Atlanta, Ga., to Miss Patricia Jane Jones of Forrest Hills, L. I., N. Y., June 30.

ALEXANDER WASHINGTON MARSHALL, Charleston, S. C., to Miss Sylvia Willis Russell of Haddam, Conn., July 25.

GUY ZIMMERMAN JR., Mount Sterling, Ky., to Miss Margaret Wells of Nashville in Miami, Fla., July 25.

JAMES MCGREW LAMME JR., Walsenburg, Colo., to Miss Patricia Maria Lord of Calais, Maine, June 20.

CATHERINE BIRD HOOVER, Richmond, Va., to Lieut. Fordyce Cox Stone of Binghamton, N. Y., August 6.

TREADWELL LEWIS IRELAND, New York, to Mlle. Colette Marie Charlotte Torchet in Paris, July 30.

JOHN HAL JAMESON, Easley, S. C., to Miss Charlotte Christine Crawford of Savannah, Ga., August 4.

MARION BATES LEVLETT, McGehee, Ark., to Miss Betty Jane Perryman of Fort Smith, July 25.

HENRY THOMAS GRAY, Forrest City, Ark., to Miss Johanna Janke of Ponca City, Okla., in July.

Deaths

John Aloysius Quin, Rahway, N. J.; Temple University School of Medicine, Philadelphia, 1934; born in Carteret, N. J., Nov. 6, 1906; member of the American Medical Association and the Academy of Medicine of Northern New Jersey; an honorary member of the New Jersey State Firemen's Association; interned at St. Joseph's Hospital in Yonkers, N. Y.; served a residency at Newcomb Hospital in Vineland; company surgeon for the Pennsylvania Railroad; served as member of the board of water commissioners in Rahway and as examiner and surgeon for the Public Service Company in New Jersey; medical consultant to the Union County Mental Hygiene Society; a member of the medical advisory committee of the local Red Cross nursing service; member of the staffs of the Elizabeth General and St. Elizabeth hospitals in Elizabeth; president of the staff of the Rahway Memorial Hospital, where he died June 30, aged 38, of carcinoma of the stomach.

William Waddle Richardson ♂ Mercer, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1902; born in Athens, Ohio, Oct. 8, 1877; specialist certified by the American Board of Psychiatry and Neurology, Inc.; fellow of the American College of Physicians; member of the American Psychiatric Association, Association for Research in Nervous and Mental Disease and the Central Neuropsychiatric Association; past president of the Mercer County Medical Society; served in France during World War I; director of the public library and the First National Bank; president of the local Rotary Club; consulting neuropsychiatrist to the Buhl Hospital in Sharon; part owner and medical director of the Mercer Sanitarium, where he died June 10, aged 67, of cerebral hemorrhage.

Edgar Lee Sanderson, Shreveport, La.; Medical Department of Tulane University of Louisiana, New Orleans, 1908; member of the American Medical Association; fellow of the American College of Surgeons; chairman of the advisory board for the draft in western Louisiana during World War I; past president of the Shreveport Medical Society and the Louisiana State Hospital Association; served as vice president of the Louisiana State Medical Society; served as medical superintendent of the Shreveport Charity Hospital; member of the staffs of the North Louisiana and T. E. Schumpert Memorial sanitariums; died in the Highland Sanitarium June 7, aged 66, of melanosis.

Michael Valentine Ball ♂ Warren, Pa.; Jefferson Medical College of Philadelphia, 1889; at one time professor of clinical pathology at the New York Medical College and Hospital for Women, Homeopathic, New York; member of the American Academy of Ophthalmology and Otolaryngology; specialist certified by the American Board of Ophthalmology; past president of the Warren County Medical Society and the board of health of Warren; at one time school physician; on the courtesy staff of the Warren General Hospital; on the consulting staff of the Warren State Hospital; died May 26, aged 77, of coronary occlusion.

Joe Getty Reed, Larned, Kan.; University of Kansas School of Medicine, Kansas City, 1941; member of the American Medical Association; interned at Robert Pecker Hospital in Sayre, Pa.; began active duty as a first lieutenant in the medical corps, Army of the United States, on Oct. 26, 1942; served as flight surgeon with the air force at Fort George Wright, Wash., and in New Guinea and the Dutch East Indies, returning to this country because of ill health; relieved from active duty on Feb. 25, 1945, with the rank of captain; died in Los Angeles April 18, aged 31.

Hardie Lynch, Santa Monica, Calif.; Medico-Chirurgical College of Philadelphia, 1902; since 1920 affiliated with the Veterans Administration; for many years chief surgeon at the Veterans Administration Facility in Salt Lake City; formerly bacteriologist and assistant health commissioner for the board of health of Salt Lake City; served during World War I; at one time worked in the Panama Canal Zone as bacteriologist and pathologist for General Gorgas when the latter was in charge of health and sanitation there; died May 26, aged 68.

Charles Matthew Adams, Atlanta, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1913; member of the American Medical Association; on the staffs of the Crawford W. Long Memorial Hospital and St. Joseph Infirmary; died July 3, aged 73, of circulatory failure.

John Ambrose Miller Aspy ♂ Indianapolis; Indiana University School of Medicine, Indianapolis, 1917; associate in orthopedic surgery at his alma mater; examiner for the Selective Service Board; served overseas in World War I; on the staffs of the City Hospital, St. Vincent's Hospital and the Methodist Hospital, where he died June 12, aged 52, after a thyroidectomy.

Edward Francis Bacon ♂ New Orleans; Medical Department of Tulane University of Louisiana, New Orleans, 1904; served in this country and abroad during World War I; for many years associated with the city and state boards of health; died in the Hotel Dieu June 5, aged 70.

Willis L. Barris, Collingswood, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1894; died June 22, aged 76, of carcinoma of the prostate.

Robert C. Bills, Lockhart, Texas; Gate City Medical College, Texarkana, Ark., 1908; died April 25, aged 80, of cerebral hemorrhage.

Flavius Hugh Brown, Summersville, W. Va.; College of Physicians and Surgeons, Baltimore, 1911; member of the American Medical Association; past president of the Central West Virginia Medical Society; died June 8, aged 66, of cerebral hemorrhage.

Clyde Baker Callen ♂ Fayetteville, Ark.; University of Arkansas School of Medicine, Little Rock, 1914; died in the City Hospital June 8, aged 61, of metastatic cancer and arthritis.

Fredrick George Grover Carl, Buffalo; University of Buffalo School of Medicine, 1923; member of the American Medical Association; on the courtesy staff of the Millard Fillmore Hospital; died May 7, aged 53, of carcinoma of the rectum.

Maurice David Chernoff ♂ Chicago; Chicago Medical School, 1927; on the staffs of the Mount Sinai Hospital and the Garfield Park Hospital, where he died July 13, aged 43, of cerebral hemorrhage.

George Colville Croston, Sapulpa, Okla.; Northwestern University Medical School, Chicago, 1905; member of the American Medical Association; served as president of the Creek County Medical Society; physician for the draft board during World Wars I and II; on the staff of the Sapulpa City Hospital; died in a hospital at Vinita May 30, aged 67, of heart disease.

David Telle Dickey, Seattle; St. Louis College of Physicians and Surgeons, 1895; died May 21, aged 74, of cerebral hemorrhage.

Shirley Edward Dunlap, Wiggins, Miss.; University of Nashville (Tenn.) Medical Department, 1906; member of the American Medical Association; past president of the Coast Counties Medical Society; served as mayor of Wiggins; local surgeon for the Illinois Central Railroad; secretary of the Appeal Board number 6, Selective Service System, Hattiesburg; president of the Bank of Wiggins; past president of the Wiggins Rotary Club; died in the Touro Infirmary, New Orleans, June 10, aged 65, of coronary thrombosis.

Walter John Eilerts ♂ Wichita, Kan.; National University of Arts and Sciences Medical Department, St. Louis, 1915; served on the state board of health; on the staffs of the Wichita Hospital, St. Joseph Hospital and the Wesley Hospital, where he died July 9, aged 64, of coronary occlusion.

Erastus Talbot Farrens, Clarinda, Iowa; Missouri Medical College, St. Louis, 1881; died June 2, aged 89, of senility.

Clarence Gardinier, Schenectady, N. Y.; Albany Medical College, 1914; member of the American Medical Association; formerly medical examiner and surgical supervisor for the General Electric Company; served during World War I; died in the Ellis Hospital May 23, aged 55, of intestinal hemorrhage and hypertension.

Thomas Leslie Giles, Toshes, Va.; Hospital College of Medicine, Louisville, Ky., 1905; died in the Memorial Hospital, Lynchburg, May 5, aged 66, of myocarditis.

Lorin Arthur Greene ♂ Lieutenant Colonel, U. S. Army, retired, Gainesville, Fla.; Memphis (Tenn.) Hospital Medical College, 1902; served during World War I; entered the medical corps of the U. S. Army as a major in July 1920; retired June 30, 1939; died January 8, aged 65, of coronary thrombosis.

Edward Theodorick Haskins, Newbern, Tenn.; Vanderbilt University School of Medicine, Nashville, 1895; member of the American Medical Association; died June 16, aged 71, of myocardial failure.

John Madison Hench @ Stockton, Calif.; College of Physicians and Surgeons of Chicago. School of Medicine of the University of Illinois, 1906; served during World War I; died May 7, aged 71, of coronary occlusion and diabetes mellitus.

Thomas William White Little, Cedar Rapids, Iowa; Keokuk Medical College, College of Physicians and Surgeons, 1900; died in the Mercy Hospital May 3, aged 80, of cerebral hemorrhage.

Victor Donaldson Long, Wilmington, Del.; Hahnemann Medical College and Hospital of Philadelphia, 1928; died in the Friends Hospital, Philadelphia, May 19, aged 41, of toxic psychosis.

Francis Gerald McCarty, Niagara Falls, N. Y.; Loyola University School of Medicine, Chicago, 1930; served as a first lieutenant in the medical corps, Army of the United States, from March 1941 to November 1941, when he was discharged because of physical disability; member of the staffs of the Mount St. Mary's Hospital and the Niagara Falls Memorial Hospital; on the courtesy staff of the Sisters of Charity Hospital in Buffalo; died May 8, aged 42, of coronary sclerosis.

Nettie Andre Belau Moss, Detroit; Ohio Medical University, Columbus, 1896; died May 25, aged 71, of cerebral hemorrhage.

James Fowler Pressly @ San Francisco; Medical Department of the University of California, 1902; died May 25, aged 70, of myocardial insufficiency.

Samuel Watt Riggs, Pleasant Hill, Ala.; College of Physicians and Surgeons, Baltimore, 1893; member of the American Medical Association; died in the Selma Baptist Hospital, Selma, May 31, aged 74, of coronary thrombosis.

Harry Arthur Seigall, Hartford, Conn.; University of Vermont College of Medicine, Burlington, 1914; awarded the Purple Heart and the Silver Star for service during World War I; interned at St. Francis Hospital, where he remained a member of the staff; formerly chief of staff, Mount Sinai Hospital; died in the Mayo Clinic, Rochester, Minn., June 29, aged 54, of hereditary hemorrhagic telangiectasis.

Daniel Boteler Sprecher, Hollidaysburg, Pa.; College of Physicians and Surgeons, Baltimore, 1881; member of the American Medical Association and the Medical and Chirurgical Faculty of Maryland; for many years surgeon for the Baltimore and Ohio Railroad Company; died in Altoona, June 17, aged 90, of uremia.

Joseph Clinton Starbuck @ Media, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1894; at one time represented Delaware County on the state board of health; served as staff physician for the Glen Mills (Pa.) Boys School and the Philadelphia Orphanage; died June 21, aged 79, of chronic myocarditis.

Grady Erastus Stone, King, N. C.; North Carolina Medical College, Charlotte, 1915; member of the American Medical Association; died June 21, aged 53, of coronary occlusion.

Martin Joseph Sweeney, Redlands, Calif.; Bellevue Hospital Medical College, New York, 1893; served on the staff of the Kane Summit Hospital and the board of education in Kane, Pa.; died June 8, aged 77, of coronary occlusion.

J. G. Taylor, Farmerville, La.; Louisville (Ky.) Medical College, 1894; coroner of Union Parish; died May 16, aged 77.

Willis Carver Templer @ Corning, N. Y.; University of Buffalo School of Medicine, 1920; served as president of the New York State Society of Industrial Medicine; medical director of the Corning Glass Works; surgeon at the Corning Hospital; consultant in industrial hygiene at the Strong Memorial Hospital in Rochester; died in the Clifton Springs Sanitarium and Clinic, Clifton Springs, May 12, aged 48, of cirrhosis of the liver and rheumatic heart disease.

Clarence Edgar Thompson @ Saco, Maine; Medical School of Maine, Portland, 1901; served on the staffs of the Eastern Maine General Hospital in Bangor and the Webber Hospital in Biddeford; died June 2, aged 69, of coronary disease.

Charles Whelan @ Boston; Tufts College Medical School, Boston, 1905; specialist certified by the American Board of Radiology, Inc.; member of the New England Roentgen Ray Society, Radiological Society of North America, Inc., and the American College of Radiology; served during World War I; for several years chief radiologist at the Quincy City Hospital; Quincy; consultant in roentgenology at the Carney Hospital and New England Hospital for Women and Children; died May 29, aged 68, of leukemia.

Bohumil Joseph Wiesner, St. Louis; American Medical College, St. Louis, 1902; formerly professor of anatomy at his alma mater; died May 31, aged 72.

Harry Dunlap Wiley @ Glencoe, Ill.; Rush Medical College, Chicago, 1899;

served as a major in the medical corps of the U. S. Army during World War I; on the staff of the Highland Park Hospital, Highland Park, where he died August 20, aged 74, of peritonitis from acute appendicitis and pernicious anemia.

LIEUT. STAFFORD M. WHEELER
(MC.), U.S.N.R., 1910-1945

KILLED IN ACTION

Stafford Manchester Wheeler, Boston; Harvard Medical School, Boston, 1937; interned in contagious diseases at Sydenham Hospital and at the Harriet Lane Home, Johns Hopkins Hospital, both in Baltimore; later became epidemiologist-in-training with the division of communicable diseases, New York State Department of Health, in order to acquire further training and experience in epidemiology and contagious diseases; served as assistant and instructor in preventive medicine and epidemiology at his alma mater and the Harvard School of Public Health; research assistant at the House of the Good Samaritan; fellow of the epidemiological section of the American Public Health Association and a member of the American Epidemiological Society, as well as of several other medical and scientific associations; early in 1941 joined the Harvard group which went to Halifax, Canada, to assist the Canadian health authorities in an investigation of an extensive epidemic of diphtheria, scarlet fever and meningococcal meningitis; in the spring of 1942 accepted an appointment as associate professor of epi-

demiology at the Columbia University College of Physicians and Surgeons and the DeLamar School of Public Health; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve in June 1942; assigned as an instructor in epidemiology at the Naval Medical School, National Naval Medical Center, Bethesda, Md., where he investigated contagious diseases in various naval installations and served a tour of submarine duty in the North Atlantic in connection with his work; stationed at Bethesda until December 1944, when he was appointed to the American Typhus Commission and assigned overseas, where he worked with a Partisan army unit in Bosnia and Herzegovina; entered Sarajevo with the Partisan army on the day it was liberated from the Germans; awarded posthumously the United States of America Typhus Commission Medal on June 11, 1945 by the Vice Admiral of the U. S. Navy; promoted to lieutenant; killed near Sarajevo, Yugoslavia, April 13, aged 34, when a land mine exploded beneath his jeep.

Correspondence

MARIHUANA PROBLEMS

To the Editor:—An editorial (THE JOURNAL, April 28, p. 1129) and two communications to the Editor (June 2, p. 383, and July 21, p. 899), in discussing the book "Marihuana Problems" by the New York City Mayor's Committee on Marihuana, have referred to the article "The Marihuana Addict in the Army" by the undersigned and Capt. Henry J. Myers, which appeared in the December 1944 issue of *War Medicine*. In the editorial our article was said to be "a devastating refutation of the information contained in the La Guardia report." In their letters both Dr. Walton and Dr. Bowman objected to this characterization of the article and endorsed the findings of the Committee report.

Although I found the book "Marihuana Problems" to contain many valuable observations, I am critical of some conclusions and omissions. For example, on page 218 of the book it is stated that "those who have been smoking marihuana for a period of years showed no mental or physical deterioration which may be attributed to the drug." Even if this conclusion applies to the marihuana users included among the Committee's subjects—and this question will be discussed later—the criticism may still be raised that the Committee did not study confirmed marihuana addicts, for example of the type and degree analyzed in our article. The Committee's report would be analogous to a study of alcohol which omitted all reference to the chronic alcoholic addict.

In my opinion, some of the most significant observations in the entire investigation are contained on page 132 of the book, in the final paragraph of the chapter on "Emotional Reactions and General Personality Structure." I quote: "When the productions (in the personality tests) of the undrugged marihuana user are studied, certain personality traits which serve to differentiate him from the nonuser and from the 'average' individual can be discerned. As a group the marihuana users studied here were either inhibited emotionally or turned in on themselves, making little response to stimuli in the world about them. People with this type of personality generally have difficulty adjusting to others and are not at ease in social situations. This withdrawal from social contacts apparently finds little compensatory or sublimating activity elsewhere. These subjects did not have a desire or urge to occupy themselves creatively in a manner which might prove socially useful. They showed a tendency to drift along in passive fashion and gave a good portion of their attention to relatively unimportant matters. These men were poorly adjusted, lonely and insecure. As indicated by their history they seldom achieved good heterosexual adjustment." It is a serious omission that, in the summary chapter of the book, no mention is made of this aspect of the psychologic investigation.

Moreover, on page 218 appears the conclusion "Marihuana does not change the basic personality structure of the individual. It lessens inhibition and this brings out what is latent in his thoughts and emotions but it does not evoke responses which would otherwise be totally alien to him." It seems likely that the Committee, in its apparently dispassionate effort to counteract widely held but perhaps alarmist views of the extreme dangers of marihuana—that it causes otherwise normal individuals to commit violent crimes, to become oversexed and so on—has leaned too far backward and has minimized the long-term noxious effects of a substance which, according to the Committee's own observation, enhances, fosters and reinforces all the personality traits and tendencies mentioned on page 132 of the book.

Finally, it seems a pity that in such an elaborate study, which included psychologic, psychiatric and sociologic investigation, there is no attempt to determine the etiologic factors,

either personal or social, leading to the use of marihuana. There is the statement on page 214, in the summary, "The marihuana users with whom contact was made in this study were persons without steady employment. The majority fall in the age group of 20 to 30 years. Idle and lacking initiative, they suffer boredom and seek distraction. Smoking is indulged in for the sake of conviviality and sociability and because it affords a temporary feeling of adequacy in meeting disturbing situations."

There is no apparent interest in the reasons for its widespread use in Harlem, why the users are "without steady employment, idle, lacking initiative" and so on.

In our study of 35 marihuana addicts in the Army, it was glaringly obvious that "their backgrounds were heavily loaded with adverse familial, social and economic factors," that "the personality pictures (of the marihuana addicts) show a typical pattern of response to repeated (actual) situations of frustration and deprivation," that "a completely adequate estimate of the effects of marihuana can be obtained only from viewing its use as part of an entire life pattern" and that "the problem is not the drug but the user of the drug" and, I might add, the social, economic, cultural milieu in which the drug user's development is fostered.

The obvious implication of the Committee's report, despite the fact that it is not explicitly stated, is that marihuana is essentially a harmless drug, used by inadequate persons as a means of obtaining a little fun out of life and is nothing to become alarmed about.

Such a conclusion might seem justified from the observations recorded. However, in spite of the appearance of scientific care and objectivity in the report, the final picture is of necessity a distortion because, in spite of the planning and the diverse approach, attention was focused on peripheral aspects but not primarily on the core of the problem, the user of the drug and the environmental forces affecting his development.

ELI MARCOVITZ, CAPTAIN, M. C., A. U. S.

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II, Nov. 12-14. Part III, New York City, Oct. 15-17; Boston, Oct. 16-17. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th Street, Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various centers, Jan. 18. Final date for filing application is Oct. 20. *Oral*. Various centers, Oct. 1946. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 24.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral*. Chicago, May 27. Final date for filing application is Feb. 1. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I. Various centers, Feb. 2. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Jan. 18-22 and Los Angeles, Jan. 28-Feb. 1. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 3-6 (canceled). Spring 1946. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written*. Locally, Oct. 19. *Oral*. Atlantic City, Dec. 7-8. Sec., Dr. C. A. Alarich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written*. Part I. Spring 1946. Final date for filing application is Dec. 1. Sec., Dr. J. Stewart Rodman, 225 South 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written*. Various centers, Dec. 9. *Oral*. Chicago, February 1946. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

APPROVED RESIDENCIES AND FELLOWSHIPS FOR VETERAN AND CIVILIAN PHYSICIANS

Hospitals, 736; Assistant Residencies, Residencies and Fellowships, 7,666

The following educational services investigated and approved by the Council on Medical Education and Hospitals are considered in position to furnish acceptable residency training in accordance with standards adopted by the American Medical Association. In practically all fields these training programs have been reviewed in collaboration with the respective specialty boards. Included in the present list is the expanded number of residencies now available in those approved hospitals which have completed their plans to provide further opportunities for returning medical officers. Many additional residencies recently organized or in process of development may soon be added to the approved list. All arrangements for appointments should be made directly with the hospital concerned in the usual manner.

Discharged medical officers appointed by hospitals need not be counted in the regular residency quota allotted to individual hospitals by the Procurement and Assignment Service.

The star (*) indicates hospitals that are also approved for the training of interns. All hospitals on the approved intern list are likewise accredited for mixed residencies which represent general house staff assignments following the internship.

Mayo Foundation Fellowships—The Mayo Foundation for Medical Education and Research, Rochester, Minn.; D. C. Balfour, director; three-year fellowships, beginning quarterly, leading to the degree of M.S. or Ph.D. with field named from the University of Minnesota; in Anesthesia, Derma-
tology and Syphilology, Internal Medicine, Neurology and Psychiatry, Neurosurgery, Obstetrics and Gynecology, Ophthalmology, Orthopedic
Surgery, Otolaryngology, Pathology, Pediatrics, Physical Medicine, Plastic Surgery, Proctology, Radiology, Surgery, Urology; stipend \$900 per year.
(clinical fellowships including pathology and radiology—tentative estimate, 400).

a. Compensation arranged by medical school and hospital.

b. As reported in previous list.

c. In lieu of maintenance.

d. Residency in epilepsy.

e. Obstetrical training at Herman Kiefer Hospital, Detroit.

f. Training in gynecology at City of Detroit Receiving Hospital.

g. Assignments in psychosomatic medicine also available.

h. Fellowship offered in affiliation with Northwestern University
Medical School, St. Luke's Hospital and Wesley Memorial
Hospital, Chicago.

i. Outpatient and home delivery service only.

k. Training in gynecology at Barnes Hospital, St. Louis.

1. Approved by the Board as offering satisfactory one year training.

2. Approved by the Board as offering satisfactory two year training.

3. Approved by the Board as offering satisfactory three year training.

4. Residencies open to women.

5. Clinical data include psychiatry.

6. Inpatients: Data refer to total inpatients treated in specialty.
Obstetrical admissions do not include newborn. In pathology
and anesthesiology total hospital admissions are used.

7. Clinical data include neurology.

8. Includes fellowships.

9. Affiliated with Northwest Clinic, Minot.

10. Includes acceptable affiliate assignment at Urologic Clinic,
Philadelphia.11. Includes affiliate service at South Bend Medical Laboratory,
St. Joseph Hospital, South Bend; Elkhart General Hospital,
Elkhart and St. Joseph's Hospital, Mishawaka, Ind.12. Represents training acceptable to Board in (1) radiology, (2)
roentgenology, (3) therapeutic radiology or (4) diagnostic
roentgenology.

13. Affiliated with North Carolina Orthopedic Hospital, Gastonia.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American J. of Obstetrics and Gynecology, St. Louis 50:1-118 (July) 1945

- Carcinoma of Uterine Cervix: Interval Report on Treatment, Results and Complications. G. V. S. Smith and R. Dresser.—p. 1.
Transplantable Rat Tumor. R. M. Watts and F. L. Adair.—p. 11.
Cesarean Section Mortality. W. J. Dieckmann.—p. 28.
Serum Protein in Normal and Toxemic Pregnancy. R. E. Rinchart.—p. 48.
Treatment of Functional Dysmenorrhea with Pregnenolone. F. E. Harding.—p. 56.
Possible Role of Bacterial Synergism in Puerperal Infections Due to Anaerobic Streptococci. S. R. Steinhorn.—p. 63.
Experience with Continuous Caudal Analgesia in Obstetrics at University of Michigan Hospital: Report of 250 Consecutive Cases. G. J. Andros and C. W. Henderson.—p. 68.
Cesarean Section Under Fractional Spinal Anesthesia. W. Levine.—p. 75.
Circulation of Amniotic Fluid. W. F. Mengert and J. W. Bourland.—p. 79.
*Vitamin E in Menopause: Preliminary Report of Experimental and Clinical Study. C. J. Christy.—p. 84.
*Sulfonamide and Stilbestrol Therapy in Gonococcal Vulvovaginitis. Lucile R. Hac, H. C. Hesselstine, F. L. Adair and Myrtle B. Crudim.—p. 88.
Craniotomy, with Review of Cases. J. I. Kushner and A. C. Posner.—p. 95.
Essential Dysmenorrhea—Its Treatment with Pavatrine: Preliminary Report. C. H. Weinberg.—p. 98.
Test Case to Show Value of Cervical Cytology Smear in Uterine Cancer Diagnosis. J. E. Ayre, W. A. G. Bauld and P. J. Kearns.—p. 102.
Parovarian Cyst Causing Dystocia. W. Downing and L. O'Toole.—p. 106.
Intraperitoneal Nabothian Cyst. R. T. Frank.—p. 107.
Avulsion Defects of Scalp of Newborn Infant: Medicolegal Implications. W. J. Finegold and E. B. Schuster.—p. 108.

Vitamin E in Menopause.—Christy gave vitamin E in the form of a synthetic preparation, ephynal acetate, in 10 mg. tablets, to 25 patients ranging from 22 to 55 years. Of this group 12 had carcinoma of the cervix, 1 had adenocarcinoma of the fundus, 1 had malignant leiomyoma and sarcoma of the uterus, 6 had fibroids, 1 had carcinoma of the ovary, 1 had hemangioendothelioma of the parametrium, 1 had postmenopausal bleeding after estrogenic therapy, 1 had dysfunctional uterine bleeding due to endocrine disorder and 1 had endometriosis. No patient was treated who did not complain of severe symptoms of vasomotor instability. The amount of the drug taken varied from 10 to 30 mg. a day, depending on the degree of severity of symptoms, over periods of from one to six weeks. Seven patients reported complete and 16 great relief. The relief of symptoms in patients after administration of vitamin E could not be distinguished from that obtained with the natural or synthetic estrogens. In some cases vitamin E seems more effective in relieving the symptoms of vasomotor instability than estrogens. The chief advantage over estrogen is that vitamin E is free of any stimulative effect on the genital system or on the parenchyma of the breast. It plays no carcinogenic role as the estrogens may do and therefore can be used freely in menopausal patients with neoplastic disease. It is well tolerated.

Sulfonamide and Diethylstilbestrol in Gonococcal Vulvovaginitis.—According to Hac and her associates, of 135 children with gonococcal vulvovaginitis treated with sulfanilamide, sulfapyridine or sulfathiazole and observed one year following therapy, equally good results were obtained with sulfapyridine and sulfathiazole whether the response was based on cure (both 89 per cent) or on initial failure (sulfapyridine 5 per cent, sulfathiazole 6 per cent). Sulfapyridine caused more minor toxic symptoms than did sulfathiazole. Sulfanilamide is definitely contraindicated because of the higher percentages of failure and because it tends to produce strains of

gonococci which are resistant to sulfonamides. Of 35 children treated with sulfadiazine and observed three months following therapy, 89 per cent were cured and 6 per cent were initial failures. Diethylstilbestrol was useful in the treatment of sulfonamide resistant cases. Negative cultures for three months are probably sufficient criteria to establish a cure. Patients under treatment and observation may be permitted to return to school as soon as cultures have become negative.

American Journal of Pathology, Ann Arbor, Mich. 21:567-820 (July) 1945

- *Vaginal Smear in Diagnosis of Carcinoma of Uterus. O. Gates and S. Warren.—p. 567.
*Comparative Study of Pathology of Scrub Typhus (Tsutsugamushi Disease) and Other Rickettsial Diseases. A. C. Allen and Sophie Spitz.—p. 603.
Malignant Lymphoma (So-Called Leukemia) in Dogs. F. Bloom and L. M. Meyer.—p. 683.
Internal Lesions in Burns, with Special Reference to Liver and Splenic Nodules: Analysis of 96 Autopsies. R. D. Baker.—p. 717.
"Masson Body" in Rheumatic Pneumonia. P. A. Herbut and W. E. Manges.—p. 741.
Reaction of Reticuloendothelial System in Experimental Brucellosis of Dogs. G. Margolis, W. D. Forbus and G. P. Kerby.—p. 753.
Failure of Pressor Drugs to Influence "Juxtaglomerular Apparatus" in Rats. J. Graef and G. G. Proskauer.—p. 779.
Primary Intracranial Chorionepithelioma with Metastases to Lungs. R. E. Stowell, E. Sachs and W. O. Russell.—p. 787.
Renal Injury in Rat Following Administration of Serine by Stomach Tube. R. P. Morehead, W. H. Fishman and C. Artom.—p. 803.

Vaginal Smear in Diagnosis of Carcinoma of Uterus.—During the period from February through Nov. 15, 1944 Gates and Warren examined 341 vaginal smears from 233 patients. The stain recommended by Papanicolaou and Traut was used for nearly all smears. The others were stained with hematoxylin and eosin and were quite satisfactory. The authors think that a mistaken positive diagnosis of a negative smear should be a problem only in exceptional cases of radiation reaction or of senile atrophy with infection. False negative diagnoses are more difficult to avoid. There are certain types of carcinoma cell which are difficult to recognize without a good deal of experience. Interpretation of smears made after radiation treatment demands more experience than other smears because of the changes in epithelium induced by radiation. The smear may be valuable in diagnosis to detect recurrence after radiation, since in these cases biopsy is preferably avoided. As a subsidiary test the vaginal smear may be especially useful in cases of "hidden" carcinoma. It may be of value as a screening test for detecting the existence of cervical or endometrial cancer in large groups of women.

Pathology of Tsutsugamushi Fever and Other Rickettsial Diseases.—Allen and Spitz studied the histologic preparations and protocols of 78 cases of tsutsugamushi disease (scrub typhus), 24 cases of epidemic (louse borne) typhus, 12 cases of Rocky Mountain spotted fever and the sections of lungs of 2 cases of American Q fever. The primary lesion, or eschar, is considered to be provoked by the combined action of the secretion of the larval mite and the inoculated rickettsias. It is suggested that the absence of the eschar in certain instances of scrub typhus may be due to variations in cutaneous immunity. Interstitial pneumonitis is common in scrub typhus, in contrast with epidemic typhus and Rocky Mountain spotted fever. The histologic picture of the interstitial pneumonitis of scrub typhus is distinguishable from that of Q fever, rheumatic fever, toxoplasmosis and virus pneumonia. The amount of hepatic damage does not suggest that hypoproteinemia is due to hepatic insufficiency. Early, acute, diffuse glomerulonephritis is common in scrub typhus, epidemic typhus and Rocky Mountain spotted fever. The focal encephalitis or nodule of scrub typhus is qualitatively similar to that of epidemic typhus and is in contrast to the "microinfarct" of Rocky Mountain spotted fever. The nodules of scrub typhus and epidemic typhus are practically limited to the gray matter, whereas the encephalitis of spotted fever involves the white matter preponderantly. Contrary to the generally held impression, there is a sparsity of microscopically evident vascular damage in scrub typhus. Arteritis is exceedingly slight in scrub typhus in contrast with epidemic typhus and Rocky Mountain spotted fever. The peripheral circulatory failure in patients with rickettsial diseases is a complex phenomenon which cannot be explained solely on the basis of mor-

phologic damage to vessels. The contributory role of the adrenal gland is suggested. Evidence is presented of the lymphoblastic origin of the cells of the interstitial infiltrate. It is suggested that the large "basophilic macrophage" is identical with the "acute splenic tumor cell," and evidence is given pointing toward the association of these cells with an allergic response. The authors emphasize the importance of the indirect, possibly toxic but more likely hyperergic effects of the rickettsias on the basis of certain histologic responses which are regarded as presumptive evidence of the action of allergens. These responses include fibrinoid degeneration of collagen, necrosis of lymph nodes and spleen, predominance of the basophilic macrophage and associated cells, and acute diffuse glomerulonephritis.

Experimental Studies on Restricted Intake of B Vitamins.—Keys and his associates of the laboratory of Physiologic Hygiene of the University of Minnesota studied experimentally the relation in normal men between intake of vitamins of the B complex and various aspects of fitness. Four normal young men were maintained on a controlled dietary intake of 0.185 mg. of thiamine, 0.287 mg. of riboflavin and 3.71 mg. of niacin per thousand calories. Four other subjects were on the same diet but supplemented each day with 1 mg. of thiamine, 1 mg. of riboflavin and 10 mg. of niacin. The difference in vitamin intake was disguised by the use of placebos. Over a period of 161 days the 2 groups showed no noteworthy differential changes. The vitamin restriction was without significant effect on the aspects of "fitness," "health" and personality, but thiamine intake was on the borderline of inadequacy, as indicated by blood pyruvate. There were no signs of deleterious effects from the restriction in riboflavin and niacin. Eight young men subsisted for thirty-three days on a diet adequate except in B vitamins, which were extremely limited: 0.008 mg. of thiamine, 0.013 mg. of riboflavin and 0.1 mg. of riboflavin per thousand calories. Daily capsules provided adequate B vitamins to 4 of the men; the other 4 men received placebos. Half of the men in each group had subsisted for six months previously on an adequate intake of all nutrients except B vitamins, which were restricted to about one third of the National Research Council recommended allowances. The other men had received the same diet plus adequate supplements of the B vitamins. Accordingly there were 2 men in each of four groups with reference to previous and present diets: restricted-deficient, control-deficient, restricted-control, control-control. Anorexia, and later nausea and vomiting, began in the restricted-deficient men after about eight days and progressed to almost complete inability to eat in eighteen to twenty days. The control-deficient

men showed the same changes, with a lag of five or six days. After twenty-three days the men in both of these groups were given daily supplements of thiamine only, with a rapid return of appetite and regression of other symptoms and functional abnormalities. The restricted-deficient men showed progressive and eventually severe deterioration in endurance, coordination and "fitness," with trifling or absent effects on strength, vision, hearing and speed. Similar results were obtained with the control-deficient men, with a lag of about a week. Simple muscle efficiency was unaltered, but cardiovascular capacity and respiratory efficiency were reduced by the deficiency. All of the deficient men showed pronounced tachycardia in work, but only 1 of them developed resting bradycardia. Intellectual functions were resistant to the deficiency, but there were changes in personality toward apathy, depression and hypochondriasis. Thiamine was much the most important B vitamin in this acute restriction. The bodily stores of thiamine are effective for at most a few weeks under these conditions. The present results confirm the conclusion that the restricted diet was less than adequate or optimum, at least in thiamine, but that such inadequacy represented only a loss of a few days in the margin of safety.

Irradiation Failures in Early Cervical Cancer.—Buschke and Cantril say that even if statistically the superiority or at least equality of radiation therapy for the operable stages 1 and 2 so far has not been disproved, the fact remains that 20 per cent of stage 1 and at least 30 per cent of stage 2 cases are not cured by even the most competent and skilful radiation therapists. The question arises whether these cases represent types of the disease essentially not suitable for radiation therapy and, if so, whether possibly some of these lesions could be controlled by radical hysterectomy. Taussig's recommendation of an iliac lymphadenectomy in conjunction with irradiation, and Meigs's recent resumption of the Wertheim operation for selected cases have again stimulated interest in this problem. In 1940 the authors analyzed the failures in cases treated at the Swedish Hospital Tumor Institute between 1935 and 1938. They admit that there is a group of cases of epidermoid carcinoma of the cervix with peripheral lymph node involvement in the pelvis in which radiation therapy apparently will not accomplish a cure and in which theoretically surgery would be more promising. In their own series 4 cases out of 79 belong in this group. Three of these would not have been accepted for surgery according to Meigs's rigid standards. In Meigs's own series 9 patients belong in this group out of 65 on whom he operated. This means that 3 out of 20 would be saved, while 17 would be subjected to unnecessary surgery. Since it is impossible to recognize these cases prior to treatment, it is most likely that the actual survival rate by surgery would be smaller than if radical radiation therapy was instituted. The survey of their own material has shown that more cases were not controlled by irradiation because of some avoidable inadequacies of treatment than would have been saved by surgery of cases essentially unsuitable for irradiation. They think that improvement of radiation therapy by attention to technic, by the elimination of inadequate procedures and by the adaptation of the procedure to the individual requirements will probably save more patients than a return to surgery.

Douches.—Karnaky points out that many physicians are still prescribing alkaline substances, sodium perborate, borax, sodium bicarbonate, potassium permanganate, magnesium sulfate and sodium chloride or a combination of these, in the treatment of vaginal leukorrhea or as a cleansing douche when it is scientifically established that the normal hydrogen ion concentration of the adult vagina is acid. He thinks that acid douches (pH 3.0 to 5.0) should be used, because with pathologic changes there is hypoacidity of the vagina, and, as these changes increase, the hydrogen ion concentration approaches the alkaline side. Alkaline douches favor the growth of pathogenic organisms. The best douche found in ten years of research is vinegar. The patient should be instructed to use 5 tablespoons of vinegar to the douche bag if there is an acute vaginitis. After two weeks, 2 to 3 tablespoons is used instead of 5. For an ordinary cleansing douche 3 tablespoons of vinegar should be added to the douche bag.

Secondary Syphilis Following Penicillin Therapy of Gonorrhea.—Atcheson reports a case which demonstrates the inadequacy of treating syphilis with the same dosage of penicillin used for gonorrhea. The patient was under complete control during the entire period of observation. He was not allowed off the Army air base; hence the possibility is eliminated of syphilitic infection after the penicillin was administered. The patient demonstrated a moderate reaction to penicillin. He was discharged from the hospital eleven days after penicillin treatment. Two weeks after discharge from the hospital, twenty-five days after the penicillin was administered and thirty-two days after the supposedly infecting sexual exposure, the patient developed a maculopapular skin rash confined to the penis and scrotum. Dark field examination was positive for *Treponema pallidum*. The blood serologic test

was now positive. Diagnosis of secondary syphilis was made and the patient treated with the routine Army course of oxophenarsine hydrochloride and bismuth subsalicylate. His response has been satisfactory and uneventful.

Serum Amylase in Chronic Alcoholic Patients with Acute Abdominal Symptoms.—Carter reports 11 cases in which there was a history of chronic alcoholism and the symptoms on admission were vomiting, severe pain in the epigastrium and rigidity of the abdominal muscles, especially in the upper half, with or without tenderness in the epigastrium. In this type of case, members of the staff usually made the diagnosis of "acute alcoholic gastritis," while not infrequently an unnecessary exploratory celiotomy was done for a possible surgical lesion. In 4 of the cases operations were performed, and in each instance edema about the pancreas was noted and the peritoneal fluid was of a thin sanguineous character. In the remaining 7 cases the high amylase findings were the chief factor in deciding against operative intervention. These 7 patients were discharged well. In cases 2 and 3 amylase readings were made of the peritoneal fluid in addition to the readings in the serum, while in cases 3, 6 and 7 determinations were also made on the urine. The peritoneal fluid readings and urine amylase readings were above normal. The author concludes that serum amylase determinations should be made on all chronic alcoholic patients if operative intervention is contemplated because of severe, acute abdominal symptoms.

Crutches.—According to Deaver and Brown, good crutch walking requires a systematic program with competent instruction. This program should include a muscle test to judge the subject's joint movements and strength, exercises to develop the muscle groups needed for crutch management, proper selection of the crutches to be used, correct measurement for the crutches and determination of the crutch gaits suitable to the disability. It has been stated that a good rule for measuring crutches is to measure the distance from the patient's axilla to the floor and add 2 inches to this length. Another author indicates that crutches should measure the length from axilla to heel plus 4 inches; the handle bar should be about 4 inches less than the inside length of the area from the top of the crutches. Another opinion concerning the placement of the hand pieces is that "the distance between the top of the crutch and the hand piece should be such that by bearing down

hard on top of the crutch with one's armpit the wrist can be flexed to a right angle under the hand piece. This author also states that for the more helpless patients who use the rocking method the crutches must be longer. A dealer in crutches has figured out that the proper length of crutches will probably be 77 per cent of the height of a patient.

Tuberculosis Survey Among Ottawa Civil Servants.—

A tuberculosis survey of the Ottawa federal civil servants which lasted from Sept. 20, 1943 to March 31, 1944 revealed that among 30,260 civil servants there were 120 cases of active tuberculosis. The incidence of active tuberculosis found in this survey of what might be called a selective group is 0.39 per cent, or roughly 4 in every thousand persons examined. This was three times the average found in other Ontario surveys in 1943. Some of the reasons mentioned by Holling for the high percentage of active cases found in this survey are (a) the influx of people to the city of Ottawa and district from other provinces and sections of Ontario where the incidence of tuberculosis is much higher than the average for the province as a whole, (b) the crowded living conditions in Ottawa and (c) certain economic factors. In only 10 per cent of the 80 newly discovered cases analyzed had a physician been consulted within the past year, and a considerable number gave a history of contact and pleurisy. Also there were 32 previously known cases which were shown to have become reactivated. It is apparent from these facts that preventive services are inadequate.

Onlay Grafts Fixed with Vitallium Screws.—Meekison points to the almost universally good results obtained by the massive onlay graft for delayed union or nonunion of long bones. The massive onlay graft is a full-thickness piece of cortex of autogenous bone applied to the surface of the fragments (across the ununited gap) but not countersunk into the recipient fragments. Union takes place between the fragments and the graft and directly across the gap. Firm fixation is provided, which is essential. Fixation of the onlay graft has been done with aluminum, bronze and silver wire and kangaroo tendon. The author is not in sympathy with the use of these. Vitallium screws have greatly simplified the procedure. The massive onlay graft, fixed with vitallium screws, meets all the requirements—internal fixation, supplementary bone, osteogenic material and the stimulation of osteogenesis. In 170 cases in which this method of grafting the long bones has been employed, Meekison has had only 1 failure.

Chronic Melioidosis.—According to Mayer, melioidosis is an infective disease occurring in Burma, Ceylon, French Indo-China, the Netherlands East Indies, Malaya and Siam. It is a disease of rodents and man; it is assumed that infection in man is acquired from infected rodents, possibly by contaminated food or water supplies. The causative organism was named *Bacillus whittmori* by Stanton and Fletcher in 1921 but was assigned to the *Pfeifferella* group of bacteria by Topley and Wilson and is now known as *Pfeifferella whittmori* or *Malleomyces pseudomallei*. In most cases the disease has been acute, with symptoms simulating cholera or typhoid, and has proved fatal from septicemia within a few days or weeks. At necropsy the commonest findings have been areas of consolidation and small abscesses in the lungs, and abscesses or areas of caseation in the spleen, liver and kidneys. The chronic form of this disease is far less common. The author reports chronic melioidosis in a man aged 33. Some of the lesions primarily involved bone and others cartilage. Much of the patient's improvement may be attributed to the combination of autogenous vaccine and sulfadiazine therapy. An important principle in the treatment of melioidosis is that the abscesses, unlike those of tuberculosis, should be drained early and adequately. Abscess formation was accompanied by a deterioration in the general condition, which improved following the institution of adequate drainage.

Psychodynamics in Criminal Behavior. D. Abrahamson.—p. 65.

Intracranial Pressure and Blood in Cerebrospinal Fluid After Head Injuries.—According to Friedman and Merritt, injuries to the head are often followed by persistent symptoms such as headaches, dizziness, loss of ability to concentrate and irritability. There are two divergent opinions: (1) that the symptoms are the results of structural changes in the brain or functional alteration of its circulation; (2) that they are due to psychologic reaction of the patient to the injury. The authors present data regarding the cerebrospinal fluid pressure and the presence of blood in the cerebrospinal fluid immediately following the injury in 265 patients with acute head injuries. These findings are correlated with the occurrence of headaches during the patient's stay in the hospital and for periods varying from two to twelve months after the injury. The incidence of headaches in the immediate post-traumatic period did not occur in a significantly higher percentage of the patients with an increased cerebrospinal fluid pressure or a bloody cerebrospinal fluid than in those with normal intracranial pressure or a clear spinal fluid. Headaches persisting for longer than two months following the injury occurred in a slightly higher percentage of the patients who had an increased cerebrospinal fluid pressure than in those with a normal pressure immediately following the injury. Headaches persisting for more than two months following the injury occurred in approximately the same percentage of patients who had a bloody cerebrospinal fluid as in those patients who had a clear fluid immediately after the injury. The authors conclude that headaches persisting for several months after a head injury cannot be related directly to the pathology of the brain injury.

Spinal Epidural Abscess Complicating Spinal Puncture.—Rangell and Glassman state that no case of epidural abscess has ever been reported following routine spinal puncture. They report the case of a soldier aged 28 in whom a lumbar puncture was followed successively by excruciating and pro-

gressive root pains, sphincter disturbances and a flaccid paraplegia. Because of localized pain, swelling, tenderness and spasm in the paravertebral muscles, fever, toxicity, systemic signs of infection, and objective findings of a cauda equina syndrome, a diagnosis was made of acute epidural abscess in the cauda equina region. Operation was performed and resulted in the finding of a thick, creamy, white pus in the region of the periosteum of the third and fourth lumbar spinous processes. Laminectomy was performed and the pus was seen to gush from an abscess in the epidural space. Following evacuation of pus a soft rubber catheter was passed cephalad through the epidural space to the level of the tenth thoracic vertebra, and no further pus was obtained. At no time was the dura opened. Sulfanilamide was sprinkled into the wound, and a Penrose drain was inserted upward under the arch of the second lumbar vertebra before closing. Improvement began promptly following the operation. Six weeks later the patient was up in a wheel chair and receiving daily physical therapy. There was a complete return of sensation and sphincter control but only a partial return of motor function.

Succinylsulfathiazole and Phthalylsulfathiazole in Surgery of Colon.—According to Poth the mortality of surgery of the colon has been reduced more in recent years than is explainable by improvement in surgical technic. The evidence which has accumulated over the past four years indicates that succinylsulfathiazole (sulfasuxidine) and phthalylsulfathiazole (sulfathalidine), when given in adequate doses, are bacteriostatic agents which will produce a significant modification of the bacterial flora of the bowel and that their proper administration will help to give a satisfactory mechanical preparation of the bowel preceding surgical operations while the patient is maintained on an adequate protein and carbohydrate diet. Acylated sulfonamides alter and simplify the bacterial flora of the gastrointestinal tract. The question is raised as to whether such a modification is of practical value in making surgery of the large bowel a safer procedure. The first report on a series of 50 patients receiving succinylsulfathiazole both preoperatively and postoperatively when operations were performed on the colon was by Poth in 1942. No fecal fistulas developed, there were no instances of peritonitis and there were no deaths. In 1943 Allen expressed the opinion that with the use of succinylsulfathiazole there was a tendency to increase the number of single stage operations on the large bowel. By 1945,

this author considers phthalylsulfathiazole the drug of choice for the preoperative management of patients with carcinomas of the colon, because this drug shows no tendency to cause increased hemorrhage from ulcerating lesions. Both emphasize that succinylsulfathiazole and phthalylsulfathiazole are properly used only as aids in colonic surgery and should not encourage a breakdown in surgical principles. So-called aseptic procedures should be used whenever possible, but, when necessary, an open anastomosis can be done with a greater degree of safety than was possible formerly.

Mechanism of Fatal Blast Injury of Lung.—In recent experiments on the production of emphysema by overdistention of the lung with increased intrabronchial pressure it was noted by one of the authors that if the dogs coughed and thus increased the pressure they suddenly died. At necropsies it was noted that air emboli were present in the coronary vessels. Eighteen dogs were subjected to increased intrabronchial pressure. The first group of 8 dogs was subjected to pressures of from 35 to 50 mm. of mercury for a period of a few seconds to fifteen minutes. The second group of 10 animals was subjected to a blast varying from 70 to 110 mm. of mercury. Two animals received a blast of 120 and 240 mm. of mercury, respectively. The animals of the first group died after an episode of coughing. Those of the second group died within a few seconds to three minutes after the blast. The cause of death was found to be air embolism in 15, with pneumothorax as a contributory factor in 8. Pneumothorax appeared to be the sole cause of death in the remaining 3. Other gross findings noted in these animals were similar to those reported in human beings following blast injury. In some patients dying immediately after a blast injury the cause of death has not been adequately explained. Coronary air embolism may be easily overlooked and might well be the cause of death in some cases of blast injury.

Malarial Papillitis.—The total number of patients examined by Lewy for evidence of papillitis was 60. Some blurring and/or color change in the optic disk was presented by 36, while the other 24 presented no change. Ocular symptoms were usually mild. Many of the patients said that their eyes tired easily. A number stated that they had blurring of their vision at about 50 yards. Many of these patients had headaches, but this had to be discounted as this symptom was common to many patients with malaria who had no ocular changes. Visual loss shown on the Snellen test chart was from 20/15 to 20/20 or 20/20 to 20/25. One patient lost vision to 20/100 in the right eye and 20/400 in the left. It is recognized that the difference between papillitis and papilledema may be slight ophthalmoscopically. It is also recognized that exudate or edema may be present in the neural or supporting tissue of the optic nerve as a product of either inflammation or stasis. This condition is considered a papillitis because of the injected appearance of the nerve head in the majority of the patients and because many showed a disturbance in the ocular physiology, e. g. diminution in visual acuity, reduced peripheral fields and enlarged blind-spot scotomas. No absolute correlation could be made between the amount of papillary change and the number of attacks of malaria. The condition has been observed in patients with one attack and with eighteen. The question may be raised whether medication is the cause. None of this group of patients presented the retinal ischemia, arterial spasm and blindness characteristic of quinine amblyopia, which is often the cause of toxic retinobulbar neuritis resulting in complete central blindness and

pallor of the disk. One patient had a characteristic picture of the nerve head although he had never received quinacrine hydrochloride. The great increase in the use of quinacrine hydrochloride coincided with a drop in the incidence of malaria and papillitis. This should remove suspicion from quinacrine hydrochloride as a causative factor. There were many patients with papillitis that never received pamaquine naphthocate.

Reason for Use of Dextrose in Diabetic Acidosis.—Peters shows that extreme reduction of carbohydrate in the diet lowers the tolerance for dextrose. The phenomena of starvation diabetes have been attributed to variations in the secretion of insulin by those who hold that every fluctuation in the combustion of carbohydrate depends on a change in the secretory activity of the islands of Langerhans. Such a theory is not compatible with the facts. Although the exact *modus operandi* of insulin on the metabolism of carbohydrate is not known, it has been established that its preponderant action is to accelerate oxidation of muscle glycogen and that it has no direct effect on the formation or breakdown of liver glycogen. Every substance that is capable of forming carbohydrate is converted to glucose by the depancreatized animal. Since almost all compounds except dextrose must be transformed to glycogen by the liver as a preliminary step in the conversion to glucose, this in itself constitutes proof that hepatic glycogenesis does not require insulin. Among the disorders encountered when the combustion of carbohydrate is impaired or retarded, the most prominent are increased protein catabolism and ketosis. The literature on diabetes in the era from 1915 until insulin was in general use abounds in papers in which acidosis is attributed to the failure of patients to adhere to dietetic regimens that could only have led to slow death from malnutrition or from tuberculosis and other diseases that prey on the malnourished. The aim of treatment was to keep the urine free from sugar, regardless of the nutritive needs of a patient. It was known that although loss of sugar in the urine increased progressively as the carbohydrate in the diet was raised above the amount required to induce glycosuria, there was a wide zone within which only a part of added increments of sugar were excreted, another example of the acceleration of carbohydrate utilization by hyperglycemia. This led some to advocate the prescription of enough carbohydrate to insure the utilization of the largest quantity that could be accomplished without producing distressing polyuria. With the advent of insulin such expedients were no longer necessary. Nevertheless, the mental attitude, including the doctrine that ketosis is the wages of dietary sin, has been slow in dying. Diabetic acidosis and the coma in which it culminates mark the most extreme diabetic state. The most urgent therapeutic indications are restoration of the fluid and salt supplies of the body and the integrity of the circulation and elimination of the ketosis and glycosuria which are responsible for the salt and water depletion. Reversal of the metabolic disorder requires the administration of insulin and the provision of sugar. The routine prescribed for the patient in diabetic acidosis consists in the injection of 50 units of insulin. An intravenous infusion of 500 cc. of 10 per cent dextrose solution is then begun, together with subcutaneous injection of isotonic solution of sodium chloride. The patient is prohibited from receiving anything by mouth. After the first priming dose of 50 Gm., dextrose is given intravenously at the rate of about 10 Gm. per hour with doses of 20 to 40 units of insulin at the same intervals until the blood sugar begins to descend definitely. At this time dextrose is given at a faster rate (about 20 Gm. per hour), while the insulin is reduced to half or less of its earlier dosage, according to the course of the blood sugar. Oral administration of fluids is not begun until the patient has been completely conscious and entirely free from all gastrointestinal symptoms for from two to six hours.

Malignant Exophthalmos.—Robertson reports 9 cases in which exophthalmos increased in spite of the relief of the toxic symptoms. The suggestion that some different factor is at work in the production of malignant exophthalmos, as against the exophthalmos of ordinary toxic diffuse goiter, receives strong presumptive evidence when we compare the age and sex grouping in the two conditions. Toxic diffuse goiter is a disease of early adult life and is much more common in females, while in the malignant type exophthalmos occurs in patients aged 40 years or over and sex incidence is almost reversed. Of the 9 patients 6 were men and 3 women. In many cases the disease gradually dies out; but it often leaves the patient with an unsightly deformity and sometimes double vision. Only occasionally has a complete regression of the exophthalmos occurred. In other cases the condition progresses until the disorganization of the eyeball is so great that excision of the globe has to be performed. It is now generally accepted that there is an edema of all the orbital tissues outside the globe, and this increase in size of the orbital contents pushes the eyeball forward. It also restricts the free movements of the eyeball. It seems certain that the hormone responsible for the orbital edema is different from the one which produces the other signs of thyrotoxicosis. Since edema is a sign of water imbalance and since water balance is influenced by the pituitary gland, a pituitary hormone may be involved. Robertson treated 4 patients with Naffziger's method of decompression of the orbit; 1 had excision of the stellate ganglion; 2 had high voltage x-ray therapy to the pituitary gland. None of these methods produced the desired results; some patients lost 1 or both eyes. Three patients, in whom the metabolic rate was slightly minus following thyroidectomy, were given thyroid when the eyelids became edematous and ophthalmoplegia appeared. The resulting increase in the metabolic rate increased the loss of body fluids and the eyes receded. In 5 cases in which no surgical measures were adopted the treatment consisted in raising the basal metabolic rate so as to increase water excretion. In all of them the disease has been controlled.

Relationship of Acne and Hypertrichosis. E. L. Cohen.—p. 102.

Penicillin Cream in Sycosis Barbae.—Burrows and his co-workers report observations on 21 patients in whom they used penicillin cream. When bacteriologic examination had disclosed that the predominant organism was penicillin sensitive the patient was provided with a pot of penicillin cream containing 200 units of penicillin per gram. The sterile cream base can be kept in screw capped jars indefinitely, and when penicillin cream is needed a jar can be warmed to 60 C. and the penicillin solution added to obtain the concentration required. Little stirring is necessary, as the penicillin diffuses readily in the cream base. The patient was instructed in the technic of the aseptic removal of the cream from the jar. A knife or a spoon can be sterilized by boiling in water for three minutes and cooled under a running tap; the cream is removed from the

jar and spread on clean lint and thence applied thinly to the affected area twice a day. Of the 21 cases of sycosis barbae investigated bacteriologically, 19 were caused by a penicillin sensitive strain of staphylococcus. Of 13 cases with a history of more than one year 6 were cleared in an average time of six weeks and 6 were improved over an average period during the same period. Of 6 cases with a history of less than one year 4 were cleared in an average time of two and one-half weeks and 1 was improving over a period of five weeks. No improvement resulted from the treatment of 2 cases due to insensitive strains of bacteria. In order to lessen the tendency to relapses the authors recommend (1) application of the penicillin cream to the anterior nares as well as to the skin of the beard area, (2) treatment of nasal discharges, blepharitis, or otitis media or externa if present, (3) treatment of any other manifestations of the seborrheic state, (4) elimination of foci of sepsis in the throat, teeth and sinuses, (5) continuation of treatment for a few weeks after apparent cure, (6) use of the cream prophylactically after relapses or if nasal swabs remain persistently positive, (7) instruction of the patient to discard his infected shaving brush and face flannel or sterilize them by boiling or to use a brushless shaving cream and (8) consideration in severe cases of the use of x-ray epilation in conjunction with penicillin.

Transient Heart Block and Coronary Occlusion in Pleural Shock. D. R. Cameron.—p. 104.

Heart Block in Diphtheria.—Cookson investigated 83 cases of diphtheria and took cardiograms at intervals throughout the illness. In 63 patients, or more than three fourths, the cardiogram was abnormal. Ten of these showed some defect of conduction; the others, inversion of T in one or more leads. Other abnormalities commonly seen were axis shift, slurring and slight widening of QRS, and bizarre P waves. Clinical and cardiographic findings are given of 8 cases showing conduction changes. Of 4 with latent block, a prolonged PR interval has persisted in 1 for five months. Bundle branch block appeared in 4 unimmunized children aged 12 or less, and all died; complete block was recorded in 1 of the 4. In 2 others bizarre ventricular complexes were found in association with a passive ectopic rhythm; at first sight these suggest a bundle branch lesion: but, like the short PR, wide QRS syndrome, which seems a related condition, these changes do not appear to have prognostic significance.

Electrocardiographic Changes and Niacin in Pellagra.

—Rachmilewitz and Braun studied the effect of niacin therapy on the cardiographic changes in 27 patients suffering from pellagra. In 16 of them with pronounced visceral manifestations of the disease the response to niacin was prompt; the cardiogram improved or returned to normal after several days of treatment. In some cases thiamine was given without any effect; these cases responded promptly to subsequent niacin treatment. In 2 cases complicated by severe hypoproteinemia the response to the first trial with niacin was slight or absent. Only after restoration of blood proteins was the effect of niacin on the cardiographic changes observed. In 9 cases in which only skin lesions were present no cardiographic abnormalities were found and no changes followed treatment.

Blood Volume Determinations with Radioactive Phosphorus.—By the application of a new method worked out by Hevesy and his co-workers, employing blood corpuscles labeled with radioactive phosphorus, Nylin determined the circulating blood volume and on both normal persons and patients with

cardiac defects with and without failure. The prerequisite for the determination of the circulating blood volume is that the dilution curves can be established and thereby the time when equilibrium appears. The results in each case were based on the mean values of a number of determinations. The mean value for the amount of the circulating blood corpuscles in normal cases was found to be 1,850 cc., 1,998 Gm., or 33.4 Gm. per kilogram of body weight. The mean value for the compensated cases is in agreement with the normal values at 1,795 cc., 1,939 Gm. and 31.8 Gm. per kilogram of body weight. The total blood volume in the normal cases is 73.5 cc. per kilogram of body weight and in the compensated cases 71.8 cc. Two cases of heart failure—and particularly 1 of them—showed a considerable increase in both the amount of blood corpuscles and the circulating blood volume. The other case has been followed with repeated determinations after all signs of failure had disappeared, a great decrease in the circulating blood volume of no less than 28 per cent taking place simultaneously with the appearance of the interesting phenomenon that the amount of red blood corpuscles also decreased by 18 per cent.

Masquerading in Uniform.—Stalker reports the histories of 7 patients guilty of unlawfully wearing military uniform or medals. All the patients showed a serious disorder of personality existing long before the war. This personality disorder was the prime cause of that form of abnormal behavior with which they reacted to the war situation. In most of the cases arrest and treatment had no remedial effect, similar behavior being repeated when opportunity came. These cases belong to Henderson's "predominantly inadequate" class of psychopathic states, described by him as almost more consistently abnormal or immoral, more malignantly involved in their individual tendency than the members of the more definitely aggressive group. It is a self centeredness which takes no thought of others and has for its aim the individual's self gratification and glorification irrespective of what consequences may follow. They are both narcissistic and exhibitionistic; altruism has little or no place. Such states of mind exhibit a detachment from reality, an altered consciousness, a form of split-mindedness where attention is difficult to gain and where phantasy and romance lead up to situations which are more or less obvious overcompensations for the failure to adapt to actual conditions. In each case there was some family history of psychosomatic, psychopathic or general psychiatric disorders but not enough to show that the patients' conditions were hereditary. A history of more physical ill health than the average was obtained in 6 of the cases, and the general physical development was poor in 3. One can see here a mechanism on adlerian lines of overcompensation for physical inferiority.

Estimating Quinacrine Hydrochloride in Urine.—The method described by King and Gilchrist for use in the field is as follows: Quinacrine hydrochloride is extracted from alkaline urine into ether or paraffin, washed with sodium hydroxide, dissolved in normal hydrochloric acid, and the color measured against yellow glass disks in a Lovibond comparator. The procedure is an adaptation of previous methods. Results by this method have agreed well with photoelectric and fluorimetric determinations of quinacrine hydrochloride in a large number of urines from patients taking the drug.

Determination of Quinacrine Hydrochloride in Plasma.—Brown and Rennie say that specimens of plasma and urine obtained from patients who are receiving a therapeutic course of quinacrine hydrochloride have shown a relation between the concentration of quinacrine hydrochloride in the plasma and urinary quinacrine hydrochloride and ammonia concentrations which is almost as strict as the relation in subjects on a suppressive quinacrine hydrochloride regimen described by the Army Malaria Research Unit. The terms of the relation are different in the two groups of patients. The terms of the equation should be defined with each new regimen of drug administration before proceeding to the indirect determination of plasma quinacrine hydrochloride through observations on the urine. The authors describe studies on patients receiving therapeutic doses and on patients receiving suppressive treatment with quinacrine hydrochloride. They give the regression equations for both groups. Indirect determination of plasma quinacrine hydrochloride from observations on the urine is almost as accurate as the direct method and is much simpler and quicker. The army malaria research unit describes a method suitable for use in field laboratories for the indirect estimation of plasma quinacrine hydrochloride in subjects on doses of 0.1 Gm. daily from analyses of urine only. The errors of this method using duplicate determinations are of the same order as those of the mean of triplicate direct determinations.

Physiologic Considerations in Vascular Surgery.

According to Rogers, repair of the arteries under war or any other conditions is but rarely possible, and if an artery has to be tied care must be taken to ensure minimal interference with peripheral circulation. The artery should be secured in two places and divided between ligatures rather than tied in continuity. Division permits the ends to retract and may suppress a generalized vasospasm. Moreover, embolism from the site of the ligation is less likely to take place from a divided vessel. It is advisable to tie the artery just below a large branch rather than to leave a blind end into which there is a blood flow with each pulse beat; for example, the femoral artery should be tied just below the origin of the profunda rather than an inch or 2 lower in Hunter's canal. Furthermore, the distal ligation should also be placed near, that is, just above, a large branch, and the intervening part of the artery should be resected. For example, in the case of the brachial artery there is less interference with the circulation in the hand and fingers if the artery is tied just distal to the origin of the superior profunda and again just proximal to the origin of the inferior profunda, and

the intervening part resected, than if the vessel is tied and divided somewhere between the two branches. The accompanying main vein should also be ligated. Rapid transfusion of 800 to 1,200 cc. of blood, by increasing the blood pressure and forcing open capillaries, has proved valuable.

Difficulties of Determining Primary Carcinoma of the Middle Ear from Its Initial Period. A. Hautant.—p. 151.

Cortical Deafness.—Lemoyne says that the auditory tract is only partially crossed and a unilateral temporal lesion does not impair hearing. It is a tract with two relays and comprises three neurons. The first neuron runs from Corti's ganglion to the bulbar nuclei; this is the cochlear nerve. The second neuron, or the bulbodiencephalic neuron, runs from the dorsal and ventral bulbar nuclei to the internal geniculate body. In this second segment the auditory tract is partly crossed. The crossed bundle comprises a superficial part (acoustic striae of the fourth ventricle), a deep part which at the level of the corpus trapezoidum constitutes the chief intercrossing of the auditory tract. The third neuron, the auditory radiations, runs from the internal geniculate body to the transverse temporal convolution, which comprises the center of the cortical projection of the auditory tract. This segment of the auditory tract assumes a special importance in the study of cortical deafness. The author presents the history of a patient presenting two associated types of disturbances: (1) a severe bilateral hypacusia with dissociation of the aerial bone perception; (2) a psychic deafness with total agnosia and disturbances of Wernicke's aphasia. He discusses the existence of cortical deafness and differentiation between cortical deafness and bilateral labyrinthine deafness. The requirement of lesions involving the two transverse temporal convolutions explains the rarity of cortical deafness. A right temporal lesion has no effect; a left temporal lesion either has no effect or causes Wernicke's aphasia; in bilateral temporal lesions either aphasia is evident or cortical deafness can pass unobserved and requires systematic investigations with the audiometer, or cortical deafness dominates but gives the impression of a labyrinthine deafness.

Acetylcholine: In Hypotension and Hypertension.—According to Danielopolu and Crivetz, acetylcholine provokes in the terminal organ a parasympathicomimetic cellular response which elicits an immediate compensatory sympathicomimetic cellular reaction, which in turn results in the liberation of sympathin. The response and the reaction form a whole, to which the authors apply the term amphomimetism. The parasympathicomimetic response is more intense than the sympathicomimetic reaction. As a result, acetylcholine has an amphomimetic action with parasympathetic predominance. It inhibits the heart and vessels. After atropine, which impedes the parasympathicomimetic action, acetylcholine becomes exclusively sympathicomimetic: from a vasodilator it becomes a vasoconstrictor. The authors have demonstrated that atropine, which in the terminal organ impedes the parasympathicomimetic action of acetylcholine, not only does not impede its epinephrine secreting action in the adrenal medulla but favors it by inactivating the cholinesterase. Investigations on the physiologic role of acetylcholine have revealed that many important organs are stimulated by it; besides, it is liberated at the level of all the synapses constituting the natural excitant of neurons and assur-

ing the circulation of the nervous influx. Regarding the therapeutic implications of their investigations, they say that what is called essential hypotension or hypoamphotony is only a vascular manifestation of the general reduction of the vegetative tonus, both sympathetic and parasympathetic. This state is accompanied by a hypofunctioning of all the organs. In these conditions the authors make daily subcutaneous injections of from 0.2 to 0.5 Gm. of acetylcholine. This substance augments the terms of all the parasympathetically controlled organs and increases the secretion of epinephrine. Acetylcholine treatment is the preeminent tonic treatment. Without waiting for a permanent increase in blood pressure, it activates the functioning of all organs and of the nervous system. Strychnine in increasing doses is added to acetylcholine because by its action on the chronaxia it augments the tonus of certain centers. In acute collapse the authors know no more effective treatment than acetylcholine after an intravenous injection of 1.5 mg. of atropine sulfate, because the acetylcholine stimulates a prolonged secretion of epinephrine, whereas the administration of epinephrine has only a fleeting effect. Strychnine is added to acetylcholine in these cases. Because acetylcholine stimulates the secretion of epinephrine even when injected subcutaneously, it is contraindicated in hypertension. It can sometimes decrease the blood pressure, but the phases of sudden hypotension alternating with hypertension constitute a danger. Acetylcholine is contraindicated when arteritis obliterans supervenes in a patient with hypertension.

Lavage of Lateral Cerebral Ventricles with 2 p-Aminosulfamide-Pyridine in Therapy of Intracranial Suppuration in Open Fractures. M. Manfredonia.—p. 727.

Pathogenesis of Acute Hemoperitoneum.—De Francesco and Di Meglio performed operations on 22 women for symptoms of acute hemoperitoneum. Spontaneous rupture of a hemorrhagic lutein cyst was the cause of bleeding. Acute pelvic varicocele, cystic degeneration and sclerosis of the ovaries were encountered in all. The authors believe that pelvic varicocele with consequent cystic sclerosis of the ovaries is caused by nutritional and vascular disorders of the lumbo-ovarian ligament. These factors are the result of repeated pregnancies, local chronic inflammation and constitutional neurohormonal deficiency. The last factor is the one most frequently encountered. It is also the cause of the transformation of the corpus luteum into a lutein cyst with fragile walls which suddenly rupture. The intervention consists in partial resection of the ovary or ignipuncture of the ovarian cysts, subtotal resection of varicose veins in the segment of the ligament most accessible during the operation and sympathectomy of the fibers which supply the ovarian ligament.

*Observations in Poliomyelitis Epidemic. K. G. Dhuner.—p. 2187.

Poliomyelitis Epidemic.—Dhuner reports that of 307 cases of poliomyelitis from the 1943 epidemic in southern Sweden 27 were fatal. There were 31 cases of polioencephalitis. In 22 women poliomyelitis was complicated by pregnancy; in the known 10 living children born neither paralysis nor muscular atrophy was demonstrable.

Book Notices

A Textbook of Ophthalmology. By Sanford R. Gifford, M.A., M.D., F.A.C.S. Third edition. Cloth. Price, \$4. Pp. 457, with 232 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

This edition, which was completed by Dr. Gifford before his death, presents a thoroughness and care of presentation similar to that characterizing the previous editions. There has been little if any change in the original text, but the author has included some of the newer advances in diagnosis and therapy. In the discussion of ptosis, which is exceptionally well covered for a small textbook, he has included the Dickey operation, which uses a fascia lata sling connecting the superior rectus muscle to the upper tarsal plate. Dr. Gifford was partial to this operation, although it has not gained universal popularity. Included is a paragraph on the subject of contact glasses, in which he is emphatic in the fact that there is considerable difficulty encountered in the wearing of them. An addition to the discussion of the treatment of glaucoma includes the use of cyclodiathermy of the ciliary body for central retinal vein thrombosis. Epidemic keratoconjunctivitis has also been included. In the brief section on cataract surgery the author is partial to a corneoscleral suture.

It is unfortunate that the use of penicillin has not been included. No mention is made of leptothrix as a cause of epiphora in the chapter on diseases of the lacrimal apparatus. There are a number of additional illustrations, some in color. Throughout the book the discussions are practical and concise, the illustrations carefully designed to supplement the text, the contents succinct and well organized. The book is deserving of its popularity and is to be recommended to the medical student and general practitioner as well as to the ophthalmologist.

Arterial Hypertension: Its Diagnosis and Treatment. By Irvine H. Page, M.D., and Arthur Curtis Corcoran, M.D. Cloth. Price, \$3.75. Pp. 352, with 12 illustrations. Chicago: Year Book Publishers, Inc., 1945.

To those who know of the work done by the authors on the treatment of hypertension with kidney extracts this book will be a surprise. Only two of its pages are devoted to the treatment of hypertension by kidney extract; and this brief section concludes with the statement that "it would be premature to attempt to form any considered judgment about these extracts."

Section I considers normal blood pressure, the classification of hypertension, tests for measuring vascular responsiveness, and early stages of hypertension. In section II, essential and malignant hypertension, the findings on physical examination, and the psychotherapy of hypertension are discussed. Section III is devoted to "the cardiovascular evolution of the disease." The basic factor in hypertension is increased vascular resistance, which is concentrated in the arterioles. The exception to this rule is found in the heart itself, where the injury is to the coronary arteries. A brief discussion of electrocardiographic changes is included in this section.

Section IV discusses hypertensive or coronary heart disease, including angina, coronary occlusion and congestive heart failure, the effects of arterial hypertension on the brain and on the kidneys, and hypertension and pregnancy. An optimistic view is taken of pregnancy in the woman with moderately elevated blood pressure. "With mild hypertension, pregnancy need not be discouraged; with severe hypertension it is contraindicated." The fetal risk, however, is much greater than is the maternal.

Section V takes up the treatment of essential hypertension. After an evaluation of the therapeutic effectiveness of thiocyanate, kidney extract and vitamin A, the authors discuss the surgical treatment of hypertension by nephrectomy in the occasional case in which unilateral kidney disease is found. Finally the various operations for removing part or all of the sympathetic nerves are considered. The conclusion is reached that "if the circumstances are suitable . . . an adequate sympathectomy can be followed by significant therapeutic results. But the suitability of the circumstances is not always easy to determine."

The clinician may question some of the authors' conclusions, which are rather dogmatic. For example, in the discussion of coronary thrombosis it is said that the blood pressure may fall greatly at the onset but "rises in forty-eight hours to its pre-infarction level and a secondary moderate decrease appears between the twelfth and the twentieth day." Most clinicians have found that the pressure may rise, even considerably, with the onset of the pain, and that it usually falls within twelve to forty-eight hours after the onset of the attack and stays down for weeks or months.

Doubtless a typographic error was responsible for the excessive dose of chloral hydrate prescribed (p. 85) in the "hypertensive mixture": 320 Gm. in a 240 cc. mixture, to be taken "4 cc. once, twice or three times a day."

In view of the widespread interest in the rice diet advocated by Dr. Walter Kempner of the Duke University School of Medicine, one wonders why mention of it was omitted, while the total sympathectomy of Grimson, who is from the same school, was discussed in detail. Kempner has reported a far larger series of cases than has Grimson.

These criticisms are not intended to detract from the value of the book. Although the mystery of arterial hypertension is still far from being solved, this is an important contribution and will help to clarify our thinking on the subject.

Modern Psychiatry. By William S. Sadler, M.D., F.A.P.A., Consulting Psychiatrist to Columbus Hospital, Chicago. Cloth. Price, \$10. Pp. 896. St. Louis: C. V. Mosby Company, 1945.

The author begins his book on psychiatry with a long section on personality problems. This is followed by chapters on the psychoneuroses, the psychoses and finally on therapeutics. Thus the approach in this book is distinctly modern, for the descriptive accounts of the various psychoses as seen in the clinic or hospital occupies only a small part of the volume. This is a distinctly individual work, reflecting the author's interest in what he terms "personology." Dr. Sadler places before the general practitioner of medicine, as well as before specialists and psychiatrists, the problems of personality and maladjustment as seen in many "normal" persons. The psychoneuroses and the psychoses are given secondary consideration. In putting the material in this order he emphasizes the larger aspects of psychiatry and minimizes the field of the custodial care of psychotic persons. The book offers a sound approach to psychiatry in general but the text is weakened by redundant material, generalizations, medical slang and repetitions. The volume would have been more useful had a competent editor removed a considerable portion of the text. It is too long for the general practitioner and too diffuse for the specialist but relatively sound for those who have the time and the inclination to read it.

Ultracentrifugal Studies on Serum and Serum Fractions. By Kai O. Pedersen. Paper. Price, 10 Swedish crowns. Pp. 178, with 34 illustrations. Uppsala: Almqvist & Wiksells Boktryckeri AB, 1945.

The appearance of this volume summarizing work carried out from 1939 to 1944 at the Institute of Physical Chemistry at Uppsala is timely, since it makes available both the experimental work and the approach to problems of an important group of scientists with whom contact has been almost non-existent during the war. The work throughout emphasizes the necessity for the use both of ultracentrifugal and of electrophoretic analysis as a guide to the study of mixtures of proteins, a point of view which is also generally accepted in this country. Dr. Pedersen reports several fundamental contributions, among which are the establishment of the profound influence of the density of the solution centrifuged on the protein pattern with the resultant demonstration and separation of the X-protein of human serum, a high molecular weight dissociable complex of albumin and globulin containing large amounts of lipid and perhaps carbohydrate. Also of great interest is the discovery that serum of the fetus and the newborn calf contains a protein with a molecular weight of 50,000, called fetuin, not present in the serum of adult animals. These studies will no doubt stimulate intensive investigation into the role of the X-protein and of the fetuins in the organism and provide the point of departure for further intriguing research on the serum proteins.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

SULFONAMIDES FOR EAR INFECTIONS

To the Editor:—How effective therapeutically are external ear medicaments containing one or more of the sulfonamides, such as Otomide and Otomason? Are there clinical or laboratory data substantiating the value and safety of these products when used in the external ear?

M.D., Missouri.

ANSWER.—Infection of the external canal may be due to bacteria or fungi. The effect of local sulfonamide therapy depends on the organism. Infections by gram positive bacteria are likely to be inhibited, while those due to the coliform group of bacilli are resistant to sulfonamides and penicillin. Powdered sulfanilamide has been shown to have a fungistatic effect on *Aspergillus*, *Penicillium* and *Mucor* infections in vitro but not on *Monilia*, the other sulfonamides having no effect. Clinical results with powdered sulfanilamide and sulfathiazole were reported to be good. Preparations of sulfonamides in a base such as glycerin are less suitable for external ear infections than the dry powder. The local use of sulfonamides offers nothing in acute middle ear suppuration. In chronic suppuration the effectiveness depends on the type of suppuration. Active bone involvement or cholesteatoma is improved only to the extent that secondary invaders are inhibited. In line with the established principle of careful cleaning and drying as the local treatment of choice for simple chronic suppuration, the dry sulfonamide powder is generally preferred to wet preparations or solutions. A local sensitivity to sulfonamides when used in the external and middle ear is relatively common.

REPEATED RABIES PROPHYLAXIS

To the Editor:—A veterinarian has found it necessary to take five series of prophylactic rabies treatments in the last few years. He has developed muscular weakness of both lower extremities, hyperesthesia to a level corresponding to the twelfth dorsal vertebra and retention of urine following the last series. As it will be necessary for him to continue to come in contact with rabid animals, I should like to know if there is any safe prophylactic to be recommended.

I. B. Oldham, M.D., Muskogee, Okla.

ANSWER.—There is no other specific preventive for rabies than rabies vaccine. It seems obvious that the veterinarian should not take any more vaccinating treatments but put his reliance on painstaking general measures to prevent rabies infection. Such infection in all probability takes place only through bites by rabid animals, but the possibility of contamination by rabid material of a wound or break in the skin or oral mucous membrane cannot be denied. Undoubtedly the five series of preventive treatments taken have left behind some degree of specific resistance.

ESTROGENIC TREATMENT OF THE MENOPAUSE

To the Editor:—A white woman aged 45 complains of vasomotor flushes, fatigue and digestive distress—especially distention. She has been examined by several physicians in the past two or three years, but no organic lesions have been found. Each has independently prescribed estrogenic therapy with prompt improvement of the nervous complaints, but she promptly develops a copious seromucinous vaginal secretion with unpleasant odor, swelling of the labia and friability of the vaginal wall, so that wiping with cotton will produce bleeding. This has resulted after diethylstilbestrol orally (0.5 to 1 mg. probably) and hypodermically, theelin (2,000 and 10,000 units), estrogenic substance (10,000 units) and estradiol benzoate (10,000 units). I have not found any information on such a complication, but on the last occasion, after estradiol benzoate (10,000 units) I gave 5 units of progesterin the next day, with subsidence of discharge and swelling in twelve hours.

C. W. Atherton, M.D., Peoria, Ill.

ANSWER.—That the nervousness and nervous indigestion, the hot flushes, the fatigue and other associated symptoms should and did subside under estrogenic treatment is the expected result. That the woman should develop an increased secretion from the glands of the uterus, cervix and vagina is the normal consequence of estrogenic stimulation of these structures. The unpleasant odor of these secretions may be due to the nature of the flora of the vagina. If there is any blood present, even in small amounts, the decomposition of this blood always causes

a disagreeable odor. It is not quite clear whether the labial condition which is described as a swelling is actually a swelling or is a return to the normal fullness and turgescence of the labia from an atrophic condition under the influence of estrogens. The so-called friability of the vaginal wall would be an exceedingly rare and abnormal condition in a woman. A possible explanation of this tendency of the vaginal wall to bleed on wiping with a pledget of cotton might be the presence of flora in the vagina which irritate the turgescence vaginal mucous membrane.

The question states that, "on the last occasion, after estradiol benzoate (10,000 units) I gave 5 units of progesterin the next day, with subsidence of discharge and swelling in twelve hours." If only one injection of 10,000 international units of estradiol benzoate was given, and one must infer from the letter that the same reaction occurred from a single injection, then it seems reasonable to surmise that the genital structures described are hypersensitive to estrogens; one would hesitate to use the word allergic in this instance. Patients are usually not allergic to steroids, but they are frequently allergic to the various oils which are used as solvents for the estrogens (peanut oil, corn oil and oil of sesame) and the radicals with which the estrogens are combined. Diethylstilbestrol is not a sterol or natural estrogen. The inquirer indicates that one injection of 5 units of progesterin the next day caused a subsidence of the discharge and the swelling in twelve hours. Progesterin acts on the genital mucous membranes only after these structures have been stimulated to growth by estrogens, and then the action of progesterin is to stimulate secretions further and not to check them. Obviously there are factors operative in the case described which are not easily explained and which require further study.

OVIDUCAL PATENCY AND FERTILITY

To the Editor:—Will you kindly explain the significance of the following clinical observations: A nulliparous white woman aged 38 has had several air insufflations performed, and in each instance closed oviducts were indicated. Similar results were obtained after ten days of antispasmodic therapy with a proprietary antispasmodic. The menstrual history is normal: menses occur every twenty-five to twenty-eight days for three or four days. Bimanual examination did not reveal any abnormalities. A uterosalpingogram with iodized oil disclosed that the uterine cavity filled completely and was fairly large; the uterus was dextroverted; the right oviduct was visualized, and was shown to be not as long as the left oviduct; the oil passed through the fimbriated end. The sphincter of the left oviduct was normal in outline; the tube was very long, with the fimbriated end pointing downward; the oil passed through the fimbriated end. A twenty-four hour examination showed a small amount of free oil in the peritoneal cavity. From the roentgen examination it was concluded that the oviducts are patent at both the inner and the outer ends. However, a subsequent air insufflation again indicated closed oviducts, except for an occasional trickle of air through the tubes. The day following this latest insufflation the patient experienced moderate pain in the left shoulder; this subsided spontaneously after twenty-four hours. Her past history is normal except for severe influenza during the epidemic of 1917. I would appreciate an explanation for the failure of air to pass through the oviducts when the uterosalpingogram showed the oviducts to be patent. What therapy could be instituted to correct this condition so that she may conceive?

M.D., New York.

ANSWER.—Not infrequently when air fails to show patency of the oviducts hysterosalpingography demonstrates that they are open; likewise the reverse is occasionally true, but there is no apparent reason for either of these phenomena. Perhaps, in the case cited, if carbon dioxide is used along with a kymograph, tubal patency will be demonstrated. Even if air and gas fail to pass through the tubes, x-ray examination has demonstrated a spill from the fimbriated ends with free oil in the peritoneal cavity. Hence a careful study should be made of both the patient and her husband for other etiologic factors. The patient is 38 years old, so that she may have quite a few anovulatory menstrual periods; a definite effort, therefore, should be made to determine the date of ovulation by temperature graphs and vaginal smears and instruction given concerning the most favorable dates for coitus. The oviducts require no treatment, but if carbon dioxide will pass, repeated insufflations may help.

CONDENSED MILK—EVAPORATED MILK

To the Editor:—My attention has been called to a reply to a query on infant feeding appearing in the June 30, 1945 issue of The Journal. The question was asked about a formula "of equal parts of condensed milk and water." Condensed milk which contains a large quantity of sugar would not be suitable for infant feeding. It is possible that the reply was written with evaporated milk in mind, which would be suitable for such use. Condensed milk and evaporated milk cannot be used interchangeably, and the distinction between them should be kept in mind.

OUR NATIONAL MEDICAL RESOURCES

THE URGENCY OF AN ANALYSIS

LIEUTENANT COLONEL MICHAEL E. DEBAKEY
MEDICAL CORPS, ARMY OF THE UNITED STATES

In a recent statement Henry L. Stimson, then Secretary of War, forcefully reminded the nation that we have come "... rather suddenly in sight of the ultimate limitations of our manpower and resources." Although the end of active fighting has brought, or will shortly bring, the solution to many of the problems which arose during the war as the result of limited or inadequate resources, both human and material, it will not, as many hopefully believe, bring a solution to all of them. This applies with special emphasis to the field of medicine.

The inadequacy of the national medical resources which became so acutely evident during the war is by no means a temporary phenomenon. It is a chronic problem. It was merely aggravated by the circumstances of war. The shortage still exists, even though the war is over, and many factors now operative threaten to make it even more acute. Economic and social forces are pressing for prompt and effective solution of problems which still are only partially defined. Some formal reorganization or redistribution of personnel and facilities is inevitable. In order to effect intelligent direction of any reorganization of medical services, however, a thorough analysis of the national medical resources in relation to the national medical needs is as urgent as it is essential.

A consideration of certain aspects of the military experience with this problem may contribute to a better understanding of its postwar significance. As in many other fields, it was necessary during the war to meet both military and civilian medical needs with such resources as currently existed and with such increments as could be provided without disruption of other military needs. There were, however, certain obvious differences between the supply of physicians and the supply of such items as automobiles and washing machines. It was inconvenient to do without the latter; it was impossible to do without the former and impossible also greatly to increase the supply at short notice. As a matter of fact the unfortunate policy of Selective Service in the last years of the war in refusing to defer prospective medical students will result for some years to come in a decrease in the usual annual increment of physicians. Had the war continued longer, this policy might well have created serious shortages in the numbers required to meet the medical needs of the nation.

The record of the U. S. Army Medical Department during the war has been justly acclaimed. The soldiers of this country were better cared for than any other soldiers in the world have ever been cared for. The wounded were saved from death and were returned to military effectiveness in numbers never before considered possible. Men were saved from disability and deformity who in previous wars would either have lost their lives or would have lived out their days in invalidism and worse.

This record was not achieved by chance. Too much credit for its accomplishment cannot be given to the wisdom and foresight and imagination of the Surgeon General of the Army. At the very beginning of the war he clearly comprehended (1) that the medical resources of the Army would necessarily be limited by the available supply of physicians and by the necessity of dividing that supply fairly between military and civilian needs and (2) that, without careful allocation of the medical personnel available for military needs, results could not be expected commensurate even with the restricted supply of physicians.

The problem which thus presented itself was solved in two ways: 1. Consultants Divisions were created representing the major divisions of medicine (medicine, surgery and neuropsychiatry) and were charged with the evaluation of the professional qualifications, that is, the medical competence, of the available personnel. 2. To each division was given the additional responsibility of so recommending the assignment of available specialized personnel that each man would be used to the best advantage in his particular field.

The Consultants Divisions of the Surgeon General's Office developed a single basic policy, namely the assignment of specialized personnel at such places as specialized needs would be likely to develop, and, vice versa, the concentration of patients with specialized clinical needs into centers in which they could be treated by specialized personnel. The placing of trained surgical teams in forward areas in the zone of combat is an illustration of the first phase of this policy. The creation of specialized centers for tropical disease, neuropsychiatric disturbances, neurologic surgery, chest surgery, plastic surgery, amputations and the like is an illustration of the second phase.

This, however, is the brighter side of the picture. The darker side is the wastage which inevitably occurred in spite of the endeavor to use the limited supply of medical personnel to the best advantage. The very constitution of our military establishment required, and still requires, the inefficient and extravagant provision of separate medical installations for the Army, the Navy, the Air Force and the Veterans Administration. Often these separate facilities were, and still are, literally side by side. Each installation was, and still

The opinions and views set forth in this article are those of the writer alone.

is, provided with a more liberal allowance of beds than its census of patients has ever required with the exception of certain hospitals, particularly in the later months of the war. Each installation was, and still is, usually staffed with adequate numbers of medical personnel, though many hospitals were, and are now, inadequately staffed from the standpoint of medical efficiency and specialized competence.

The end of active fighting has brought this whole problem sharply into focus. The war has multiplied the medical responsibilities of the nation. It has produced many thousands of sick and wounded men who under normal circumstances would have been subject only to illnesses and injuries likely to occur in perhaps the healthiest of all age groups. Some of these must be cared for in hospitals for many years to come. To the care of these casualties must be added the care of illnesses which normally occur in any large civilian population. The population of the United States, it should be added, has increased by some five million persons during the war. It should also be added that the standard of medical care expected by the public has risen in the course of the war, and that a high standard will be taken for granted for men released from the armed forces who received such care during their period of service.

The medical resources of the country are simply not adequate to meet the demands for medical care as they at present exist. The supply of physicians is not great enough numerically to provide for a high standard of medical care for both civilian and government requirements and at the same time to compensate for the waste in medical personnel and facilities which the present system permits.

From the standpoint of specialized medical competence the deficit is even more glaring than it is from the standpoint of numbers, especially in view of the highly specialized nature of many combat injuries and diseases still to be cared for. There are in the United States today some 160,000 practicing physicians, of whom only slightly more than 20,000 are certified by the various specialty boards as qualified in their chosen fields. The number of physicians who are eligible for certification and who have not taken the trouble to secure it is probably so small that those certified by the various boards may be assumed to represent the totality of competent specialists in the United States today.

During the war the weight of military authority, exercised through the Consultants Divisions, saw to it that the specialists in the Army and within the limits of the authority of the Surgeon General were placed where their competence could be most effectively utilized. When the emergency is at an end, however, almost all of these specialists will return to private civilian practice, where, in spite of the heedlessness with which the general public selects its medical advisers, competition will largely determine their distribution. The government, on the other hand, will find itself confronted with an extremely serious situation. It will be required to provide medical care for large numbers of men with diseases and injuries requiring specialized management, while at the same time it will have few, if any, specialists to care for them.

The Veterans Administration for many years to come will urgently need such specialized personnel. It is not necessary to go into the details of how good or how bad the administration's care of its sick and wounded has been in the past. The ability of its personnel can be promptly determined by an investigation as to how

many specialists certified by the various specialty boards it has on its staff at this time and what plans, if any, it has made to secure qualified personnel in the future. The categories of required medical care and an optimum provision for them may be outlined as follows:

1. Patients who require prolonged supervisory therapy, including convalescent and custodial care for chronic conditions. They would be treated in permanent veterans' facilities and would be subdivided into two groups: A, those requiring no specialized forms of treatment, who could be cared for by nonspecialized personnel, and B, those requiring highly specialized treatment for such conditions as tuberculosis, arthritis and neuropsychiatric states. The latter groups could be concentrated in establishments designated for their special needs, preferably situated near civilian medical teaching centers, where civilian specialists could share in their treatment.

2. Patients who require shorter periods of observation and treatment for acute conditions. They could be treated in civilian hospitals throughout the country designated for the purpose, by staff physicians who would be selected on the basis of certification by the various specialty boards.

Fees for hospitalization and for medical care would be paid by the Veterans Administration at generally accepted rates. Incidentally, outpatient services established on this basis would have many advantages.

The plan outlined would do away with the present duplication and waste of government medical installations and is the more justified since transportation is no longer part of the medical problem. Trains, automobiles and airplanes make central installations as practical as they are desirable.

This plan would also utilize to the fullest the available supply of specialists. That supply, it should be emphasized again, cannot be greatly increased within the immediate future. The number of medical graduates will remain limited because the number of medical schools is limited and for reasons of both finance and personnel cannot immediately be increased. The number of medical specialists is even less likely to be increased to any great degree within the immediate future, partly because the facilities for specialized training are even more sharply limited than are the facilities for undergraduate medical education and partly because of the military policies which curtailed the training of specialists during the war. Furthermore, though space does not permit detailed discussion of this aspect of the problem, it should be pointed out that on both government and civilian physicians there rests a continuing obligation to carry on scientific research, without which advances in medicine would come to an abrupt halt.

At the present time Congress is interesting itself in the provision of adequate medical care for the whole nation, and with that objective no one can reasonably quarrel. But it seems equally reasonable to suggest that before embarking on new and untested schemes, which would require the creation of large numbers of new positions and the expenditure of large amounts of money, the government should take the practical step of doing away with the extravagance and inefficiency in the medical services under its immediate control. The waste and inefficient application of our limited medical resources should no more be tolerated than should similar extravagance in the management of such physical resources as coal and oil and iron. It

also seems reasonable to demand, now that the military emergency is over, that the government make some provision either for attracting into federal service an adequate number of medical specialists or for securing the services of civilian specialists, by the plan proposed or by some other means, to care for the thousands of casualties who will require specialized management and who cannot be adequately cared for without it.

These steps, however, do not constitute the chief medical problem which confronts this country. They represent merely an approach to it. The basic problem is, paradoxically, the realization that there is a medical problem. So far that has not been done, or at least has not been done openly. For this lack of public recognition there are perhaps two reasons. The first is the almost universal failure of federal authorities to accept a concept of medical service which includes specialized as well as generalized care. The second is the fear on the part of many physicians that a well organized federal medical service would militate against the best interests of the profession. That fear is baseless. Indeed, the profession will be derelict both in its duty to the country and in the promotion of its own interests if it does not foster such a service.

Once the existence of the problem has been recognized, the first step toward its solution would be an analysis of the medical resources of the country in relation to its medical needs, civilian as well as federal, research and educational as well as purely clinical. The analysis of the federal needs should be on the basis of the needs of all its services, Army including Air Forces, Navy, Veterans and Public Health, integrated into an overall pattern and stemming from a single general agency. Not only is the present system uneconomical financially and wasteful of personnel and facilities; it actually discourages the attainment of higher standards of medical care.

An analysis such as is proposed should be made by a board appointed on the highest level. Its function should be limited to fact finding and recommendation. Its membership should be composed of both civilian and government medical and administrative personnel. The civilian component should represent educational and research as well as clinical interests, and there should be due representation from the major medical specialties. The government component should include the various branches of the armed services, the Veterans Administration and the Public Health Service. The chairman of the proposed board would necessarily have administrative ability, and his past experience should be such as to make him fully aware of all the phases of the problem without, however, personal entanglement in any of them. He should be a man possessed of knowledge, wisdom, imagination, perspicacity and, above all, courage.

The appointment of this board, and even its report and recommendations, will not, of course, solve the national medical problem. It will, however, make clear what the problem is, both absolutely and in relation to the medical resources of the country. At the present time that knowledge does not exist, and, until the exact nature of the problem is clear, attempts to solve it are little more than gestures in the dark. Indeed, attempts to solve it can be actually harmful, in that they are likely to result in further dissipation and misuse of the numerically limited medical resources and the still more limited specialized medical resources which now exist to meet both the federal needs and the civilian needs of the whole country.

X-RAY BURNS RESULTING FROM FLUOROSCOPY OF GASTRO- INTESTINAL TRACT

REPORT OF FOUR CASES INCURRED IN ONE DAY

COMMANDER L. H. GARLAND (MC), U.S.N.R.

The widespread use of small shock proof and "ray-proof" x-ray units in connection with military and industrial work is well known. Less well known is the fact that these units are just as capable of producing serious burns in both patients and operator as were the old fashioned "exposed" units of a generation ago. Indeed, many of them are more apt to be dangerous for the simple reason that, being portable and shock proof, they can be brought much closer to the patient than could the older, heavier or non-shock proof units. The lack of adequate distance between the x-ray tube and the patient's skin is one of the chief sources of danger, few persons recollecting that the intensity of output varies inversely as the square of the distance.

The accompanying table will illustrate the importance of sufficient distance between tube and patient in x-ray work of any type: The factors are the average fluoroscopic ones of 75 kilovolts and 5 milliamperes, with filter of 0.5 mm. of aluminum.

Most small portable x-ray units are customarily operated at from 60 to 80 kilovolts and at from 3 to 5

Distance, Output and Erythema Time

Distance (in Cm.) of Patient's Skin from Focal Spot of Tube	Output (In Roentgens per Minute) Measured in Air	Erythema Time (in Minutes) if Exposure is at One Sitting or at Closely Spaced Sitzings
10 cm.	250 roentgens	1 minute
25 cm.	40 roentgens	6 minutes
50 cm.	10 roentgens	14 minutes

milliamperes. Variation of these factors produces the following influence on x-ray output:

Increase of 10 kilovolts in voltage increases the output approximately double.

Increase of milliamperage increases the output in approximately direct ratio (i. e. an increase from 3 milliamperes to 6 milliamperage doubles the x-ray output).

If three factors—adequate distance, reasonable voltage and low milliamperage—are borne in mind the average operator is not likely to cause serious damage, except in connection with search for foreign bodies and the reduction of fractures. Experienced radiologists employ the fluoroscope sparingly and then only with very small beams (say 3 inches square) in aiding the search for foreign bodies. Since the vast majority of metallic foreign bodies are innocuous, most surgeons refrain from adding insult to injury by exploring for them; therefore the problem of burns from fluoroscopic aid in foreign body removal is properly small. Unfortunately the same cannot be said for the reduction of fractures. Despite the pleading of experienced orthopedists, many physicians are prone to use the fluoroscope during (instead of briefly after) the attempted reduction of fractures. Intent on examination, the seconds become minutes before the well intentioned operator has realized it, and the safe or tolerance period of fluoroscopic observation has been exceeded. The skin of the patient

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

and, too often, that of the operating surgeon, has been irreparably damaged. Sometimes the subcutaneous tissues, muscles and even bones have been permanently injured.

Less well known than the foregoing types of damage is skin damage incidental to gastrointestinal fluoroscopy. Isolated cases have been noted by many observers, but a group of 4 cases produced by a single examiner in one day must be quite rare. As an example of an isolated incident the following case may be reported:

A woman was referred for consultation on account of alleged diverticulitis of the duodenum. She had a rectangular area of skin damage about 10 by 15 cm. on the skin of her back over the right upper lumbar area. This was reddish, somewhat indurated and intermittently itching and painful. She stated that her former physician had told her she had three diverticula arising from the distal duodenum; he became so interested in her case that he demonstrated them to some colleagues, to his office nurse and to himself repeatedly over a period of a few days. As a result she incurred a serious though not permanently disabling x-ray burn.

The four cases occurring in one day developed under the following circumstances:

In May 1944 a group of young male patients were in a small military hospital in the Southwest Pacific area. The officer in charge of the medical patients decided that 8 of them needed x-ray examination of the gastrointestinal tract. He employed a small portable x-ray unit and a detachable head fluoroscope. No metal guard or cone was apparently placed on the x-ray

opened and broke spontaneously after three days. A raw painful skin surface about 5 cm. in diameter was left. One additional patient had an erythema and a few small blisters but did not develop any exfoliation or noteworthy pain.

The 4 patients were kept in the hospital for a period of approximately two months, receiving daily dressings of a white

Fig. 1.—Full view of atrophic lesion of skin and subcutaneous tissues following a single gastrointestinal examination. The physician used a small shock proof x-ray unit with head fluoroscope. This photograph and the one from which figure 2 was reproduced were made eight months after the injury (which took about four months to heal). Three other patients were similarly burned with the same unit on that day.

tube housing. Four of the patients were examined for a fairly long period, up to perhaps ten minutes each. An average of three films was made in each case.

One week later these 4 patients developed patches of "sun-burn" on their backs about the midlumbar area. Blisters devel-

Fig. 2.—Close-up view of lesion.

oped and mild sedation for pain. The lesions were quite painful at times (the pain being described as drawing and sharp). After two months 3 of the patients were discharged in care of the medical officer near their former activity, and the fourth was kept for an additional month. One of the 3 cases was subsequently skin grafted. The case illustrated herewith required further dressings for two months, at the end of which time the lesion healed up. The patient lost about 10 pounds (4.5 Kg.) in weight and developed (he claims) intermittent nocturnal backache in the lumbar area after the incident.

Examination at the time of this report, eight months after the original fluoroscopic injury, reveals a pale, whitish pink, ovoid area of atrophic skin in the left posterior lumbar area measuring 6 by 5 cm. It shows some fine central telangiectases and a periphery of dark brown pigmentation, is adherent to the underlying tissues and is partly devoid of hair. Its center is 4.5 cm. to the left of the midline and 2 cm. above the crest of the ilium.

Brief fluoroscopic examination of the upper gastrointestinal tract (performed with the patient's ventral surface nearest the tube) discloses a deformed duodenal bulb, presumably secondary to an ulcer but without visible crater at this time. The site of the burn corresponds to the greater curvature of the distal third of the stomach, an odd and inexplicable location (except in the unlikely event that tube housing itself was defective in one small area). Films of the lumbosacral spine disclose no evidence of radiation osteitis. Clinically there is no limitation of spinal movements, and except for the preexisting gastrointestinal complaints the patient is essentially well.

All 4 patients have been reassured and have been warned to avoid unnecessary exposure to radiation of any type over the involved skin area and to be careful about any skin abrasions that might develop there.

COMMENT

The series of fluoroscopic burns reported herewith could have been prevented by the following simple measures:

(a) The use of a safe distance (12 to 18 inches) between the x-ray tube and the nearest portion of the patient's skin.

(b) The use of a filter (1 mm. of aluminum or equivalent) in the x-ray beam.

(c) The use of proper speed or dispatch in examination (not over three minutes of actual exposure in any examination period; not over four such periods in a month).

(d) Adherence to standard safe factors in operating the fluoroscopic unit (voltage about 75 kilovolts, current about 3 milliamperes, beam rarely larger than 6 inches square and usually half that size, and above all proper preparation of the examiner—dark adaptation of the eyes for at least ten full minutes before commencing any fluoroscopic work).

SUMMARY

During gastrointestinal fluoroscopic examination by a physician (not a specialist) 4 patients received serious and temporarily incapacitating burns of the skin over their lumbar area, all in a single day. They were disabled for periods of three to four months, and have permanent skin and soft tissue changes in the affected areas.

Any x-ray unit is a dangerous weapon, but the small portable x-ray unit in the hands of those unfamiliar with its hazards is perhaps the most dangerous of them all, especially when used for fluoroscopy without cone or guard.

PSYCHIATRIC ORIENTATION OF THE ALCOHOLIC CRIMINAL

ROBERT V. SELIGER, M.D.

Assistant Visiting Psychiatrist, Johns Hopkins Hospital, and Executive
Director of the National Committee on Alcohol Hygiene, Inc.

BALTIMORE

IN COLLABORATION WITH VICTORIA CRANFORD

Psychotherapist, Haarlem Lodge Sanatorium

CATONSVILLE, MD.

Does alcohol inhibit or release aggressive drives and damaging activities against society that result in criminogenic behavior? This problem has been studied and discussed intensively by many investigators, but the evidence to date is insufficient for the conclusions to be clearcut or definitive. In general it has been our experience that criminal offenses against society are committed by individuals with poorly integrated personalities, emotional instability, conflicts with the environment and frustration; these are also found in many alcoholic addicts whose drinking is symptomatic of their inability to adjust themselves realistically to the environment and its demands on them.

One factor is clear, however; alcohol, pharmacologically, acts as a depressant on the nervous system resulting in relaxation (to varying degrees and extents) of judgment and control so that underlying forces—the personality dynamics—find a more direct mode of expression. While such underlying forces may be of a passive, *laissez-faire* nature as well as of an aggressive, disruptive one, the general result of the loosening of conscious control is the release of *id* urgings, in themselves amoral in tenor. Both practically and theoretically the response of the individual to alcohol is the response of the total personality, comprising the emotional maturity level and intellectual and physical endowment-equipment functioning in a specific environment and stimulated by specific environmental situa-

tions that activate internal reaction behavior patterns. This applies just as pertinently to the noncriminal as to the criminal alcoholic addict but, in contrast to the case of the social drinker, the effects of even slight loss of control is a hazard to the criminal (prison inmate, the parolee or the released convict) which the average social drinker does not face.

The individual who has a criminal record, if he faces reality, one of the prime objectives of modern penology, recognizes that "rightly or wrongly" society has judged, not interpreted, his behavior. Society rarely accepts legal justice, trial, incarceration and release at the end of the sentence as completely canceling the initial provocation and crime. It would be most unrealistic to expect such an attitude. Moreover, and as unrealistically, the criminal rarely seeks any deeper solution to his behavior, past and future, than that imposed by the prison sentence and thus on release frequently becomes recidivistic. Objectively, both society and the criminal are at fault in this shallow understanding of, and ostrich-like attitude to, psychologic factors involved in their mutual conflict. Because the results of the conflict affect the individual more painfully, one of the objectives of scientific minded and enlightened prison personnel should be a more than superficial insight into his difficulties with the end result that the criminal will develop a better understanding of the motivations that led to the commission of his unlawful acts and come to the blunt realization that he must in the future expect more of himself than of others and not feel that the world is to blame if he does not do his full part, and more.

Modern students of criminology, in their stress on the part that society plays in crime causation, would seem to be on the wrong track as far as the rehabilitation of the individual criminal is concerned. No matter how right or wrong society is, the delinquent must recognize that the majority of people do not commit crimes and that his criminal behavior is definitely indicative of underlying personality difficulties, characterized in part by an immature approach to life. The prisoner must be made to accept the fact that fundamentally it is his personality malintegration and attitudes that need correction; so long as he inwardly feels persecuted and belligerent, so long will his ultimate conduct acts continue to bring him into open conflict with the laws of society. The basic situation remains the job of becoming a respected and self-respecting individual, and this can be done only by the active cooperation of the individual. When he realizes that the job can be done and is worth doing, he has traveled the most difficult part of the road to rehabilitation.

The prisoner, and those working with him, must be aware of and accept these facts if he is to succeed in reintegrating himself with the community. He must understand that he will be on probation for a considerable period of time; that his actions will be closely scrutinized; that society will rebuff him and in some instances be frankly unjust, primarily because society still fears that he may regress to criminal actions.

The individual who has engaged in criminal behavior must, as a consequence, be prepared to meet with hostility and be taught how to meet this situation without becoming embittered and relapsing into earlier patterns of defensive aggression. He must become emotionally mature, or more mature than he was. If he fails to accept this, or if in a childish reaction of unthinking rage he strikes back at real or imagined provocation, it is he who will suffer.

So far as drinking is concerned, the prisoner should understand the far reaching effects of alcohol. If he drank before incarceration, if drinking was in any way associated with the planning or perpetration of his criminal acts, he should never drink again. Old habits of habitual reaction die hard, and under the influence of alcohol previous aggressive asocial forces may find easy expression. Once he makes a misstep under the influence of liquor, even if his conscious intentions were of the best, he finds himself back where he started from and burdened with intensified feelings of failure and self destructive emotions.

Drinking at any time, even for the social, controlled drinker who can stop at will, always leads to a temporary relaxation of judgment, discretion and control. We do not need scientific research to acquaint us with this fact. Alcohol, as stated, acts as a depressant on the nervous system: the quantitative and qualitative results depend on factors that vary between individuals and in the same individual at different times, owing to fatigue, sugar metabolism and psychologic state, including mood, thought and specific stimuli. Physiologic changes of functioning include poorer coordination of thought and muscular action, diminished sharpness of sensory perception and delayed and weaker motor performance with accompanying increase of error. Disregarding individual personality dynamics of alcoholism as a psychiatric illness symptom, the physical effects of alcohol are not conducive to controlled behavior, nor are its effects in any way predictable.

Alcoholism as a psychiatric abnormality is symptomatic of an underlying personality illness or disorder and must be treated as a psychiatric problem. That the alcoholic addict does not stop drinking in spite of painful experiences which include loss of job and prestige, physical torment and other related miseries should be adequate evidence that underlying factors are literally driving him to drink and that he is psychiatrically ill. No emotionally healthy individual deliberately does that which causes him to suffer, provided he is aware that suffering will result from such behavior. The alcoholic addict is, therefore, either unaware, is not sufficiently aware or does not want to be aware of the serious harmful consequences of his drinking to do anything constructive about his addiction. The reasons for this lack of insight are to be found in the unconscious and may be associated with such defined psychiatric groups as the feebleminded, the organic, the psychopath, the psychotic and the neurotic. Physiologic factors involved include cell changes and lowered resistance to the drug.

Alcoholism, uncontrolled drinking, leads to the following reaction types: acute pathologic intoxication with stupor, excitement or convulsions; acute and chronic alcoholic hallucinosis; delirium tremens; pronounced paranoid development; Korsakow's psychosis; mental deterioration. There may also be encephalopathies (brain lesions and organic changes) and neuropathies, including polyneuritic features and also, with the aforementioned reaction types, associated with avitaminotic conditions resulting from inadequate nourishment while drinking.

In general, alcoholic addicts may be classified into the following distinct groups: 1. Those who because of constitutional inadequacies (genogenic) are unable to meet life responsibilities and in addition to their drinking habits have other poor life habits. These individuals may eventually become deteriorated or asocial, requiring permanent mental hospitalization.

2. Those who are not too strongly endowed intellectually and emotionally and who suffer psychic frustration with underlying psychiatric disorders (manic depressive swings, schizophrenic reactions) which cause them to seek escape from life reality by means of alcohol. 3. Those who drink to flee from unpleasant life situations they cannot or do not wish to face and meet—the neurotic or psychogenic personality. 4. Those who drink to relieve various combinations of feelings of inadequacy, self consciousness, sexual maladjustment and the like. 5. Those who drink to narcotize physical or psychic pain. 6. Those who as a result of habit plus time and body changes and added strains and griefs of life develop from social drinkers into alcoholic addicts.

The dynamics of personality motivation which may be found in any of these groups are summarized as self pampering tendencies illustrated by a refusal to tolerate at all any unpleasant state of mind; a drive for self expression without the resolve to take the practical steps to attain it; a more than usual craving for excitement and pleasure of the senses; a habit of sidestepping duties and obligations leading to the habit of substituting the rosy anesthesia of alcoholic day dreams; a definite insistent need for the feeling of self confidence, self importance, calm and poise that some temporarily obtain from alcohol.

It is also our conviction that alcoholism is evidence of latent or overt homosexuality as medically defined, or of self destructive tendencies and deep lying anxieties, hostilities and tensions stretching far back to infantile formation of attitudes, sentiments and interpersonal relationships in which identification and imitation play a decisive role. Contrary to popular opinion, science has no proof that alcoholism is hereditary, although some individuals with an alcoholic ancestry may have lowered resistance or be more sensitive to alcohol. Social inheritance involving the identification and imitation mechanisms would seem to be the basic factors, not heredity as such.

Narcotization of anxiety is a major factor in the misuse of alcohol. In some cases this anxiety is the result of traumatic experiences in early childhood which the personality was unable to assimilate, while in others it may be due to unresolvable conflicts. Other types of personality makeups that seem to require the narcotization escape device include the tense, perfectionistic, worrisome individual; the individual who has a vague inner restlessness and feels himself to be a bystander, not a participant, in life; the emotionally immature individual, and the individual who is consistently inconsistent, whose main characteristic is that of unreliability—the total or partial psychopath.

PSYCHIATRIC THERAPY

Individual alcoholic therapy should begin, therefore, with a careful examination to determine the "type" of drinker, the personality makeup and the presence or absence of serious psychiatric or neurologic reactions in order to determine whether the patient should be placed in a mental hospital or on a health farm or be treated by regular office visits. The acutely intoxicated individual should, obviously, be placed in a mental hospital until the toxic condition has subsided and the patient is accessible to psychiatric examination. Psychiatric therapy consists of five separate but interrelated steps: examination and diagnosis; placement (hospital, farm, office); medical and psychiatric treatment; reeducation; continuous lifelong follow-up.

With all except the acutely intoxicated patient the usual psychiatric procedure is employed, including complete life history, neurologic and mental status surveys and personality and intelligence tests. It is well to obtain objective data from a friend or relative of the patient to provide factual information about the nature and extent of the drinking and resultant behavior changes. Personality and intelligence tests are of definite value in diagnosis and personality evaluation, especially when individuals are unaccompanied and no objective data can be immediately ascertained. Of these tests the Rorschach examination is the most useful and reliable in making a differential diagnosis, gauging the level and quality of emotional maturity, and in profile sketching the personality makeup of the individual.

Therapy and reeducation of the alcoholic patient, regardless of his place of treatment, is conducted along the following lines: Regular visits or interviews in which distributive analysis and synthesis allows the patient to ventilate and learn how to objectify his underlying stresses and tensions, interpersonal relationships and attitudes, goals and strivings, while at the same time following a regular daily routine (self imposed or controlled by the environment) and, through discussion and observation, to develop new insight, views and values. In this respect the benefits of socializing in the farm or hospital group are very important suggestive factors.

The goal of treatment is total permanent abstinence, and therapy is organized to achieve this by reeducating the individual, helping him to establish new habits of living, thinking, action and reaction to excitement, disappointment or out and out frustration. The nature of his drinking problem is explained to him and discussed by using specific examples chosen from his own life history and including dream material, present conflicts and so on. Simultaneously, certain fundamental psychology facts are reviewed to help the patient acquire enough knowledge to help himself.

Every patient presents an individual problem, and the treatment is approached from this angle. One of the greatest factors in successful rehabilitation of the alcoholic addict lies in the interpersonal relations of the patient and the physician, with general principles subordinated to the individual needs of the patient. Other necessary factors are the careful selection of voluntary patients with undamaged nervous system; the personality of the therapist, who should be kind but firm; time; suggestive influences and full cooperation of friends and family; lifelong follow-up. It must again be stressed that the alcoholic addict is a sick person and that his addiction and its causes extend over a long period of time. Thus his cure must be thought of as similar to the healing of tuberculosis scars, depending on his keeping in good mental and physical health. It is sound, practical, common sense for the ex-tuberculous patient to check with his physician periodically, and it is just as sound for the ex-alcoholic addict to do likewise. The crucial part of the treatment is to help the individual reach a level of emotional maturity which will enable him to live a relatively efficient, productive and contented life with kindly, tolerant, interpersonal relations and an inner poise and stability.

SOCIOLOGICAL FACTORS

Sociological factors play a definite part in the production of the anxieties, hostilities and frustrations which apparently produce a need in some individuals for the narcotizing effects of alcohol. America has

never been known as a nation of teetotalers, and alcoholism is certainly not unique in our time. Records dating back to early colonial times show that many people were even then seriously alarmed by the alcohol problem, which they felt was directly connected with mental illness and crime. By the early part of the nineteenth century alcoholism had come to be recognized as a serious moral and cultural problem and gave rise to a temperance movement that was for a long while overshadowed by the problem of slavery but burst into full bloom after the war between the states.

England, to name but one country, during the eighteenth century had an almost universal problem of alcoholism of the worst sort because of economic pressures of the industrial revolution resulting in widespread pauperism, rapid urbanization and cruel economic inequality. We should not blind ourselves with the thought that mankind has always suffered in various ways and that nothing under the sun is new. America was not settled by the ruminative inaction of the alcoholic addicts; rather was it settled in spite of the near universal drunkenness of the frontiersman. The distillery and the saloon were the invariable accompaniments of the frontier settler (cf. the Whisky Rebellion) and they in turn called forth their inevitable accompaniment of the revival meeting and the temperance pledge.

Within the last quarter century the trend toward the more moderate use of alcohol has been definitely reversed and there is a decided increase of alcoholism in all groups and ages. Some statistical surveys set the figures currently at 600,000 chronic alcoholic addicts (this does not include those who have not been admitted to hospitals), 2,000,000 heavy drinkers and about 38,000,000 social drinkers. Excluding the non-scientific experiment of Prohibition, which blossomed from the work of various sincere and well intentioned groups, we have never until recently made any organized attempt to attack this problem on a medical or coordinated basis in spite of the thousands of arrests, admissions to city psychopathic and state mental hospitals, of accidents due to alcoholism and the testimony of social workers and reformers as to the damage to life, health and property due to alcoholism.

In England, where social problems were attacked publicly for many years, Fleming reported in 1937 an 80 per cent decrease in arrests for alcoholism over a twenty-five year period due, he felt, to:

1. Social legislation.
2. Labor receiving equal rights and equal responsibilities with capital and management.
3. Legislated restricted hours of sale of alcoholic beverages.
4. More diversion on an active participating level of the white collar and working groups.
5. Temperance societies, active social service work with the individual and the family unit.

While Fleming's reasons are a patent oversimplification of an England ruled by the Tory party, racked by the great depression, housed in horrible shums and honeycombed with slowly dying blighted areas, it is interesting to contrast his analysis with the present American scene:

1. Large mobile population groups with little family cohesion, tradition of residence or homogeneity.
2. No decided social legislation until recently; no definite public disapproval of drunkenness.
3. Labor receiving "equal rights" but, as yet, not equal responsibilities and little or no political representation.

4. No restricted hours of sale of alcoholic beverages except in some states.

5. Fewer socially utilized opportunities for diversion or creative recreation.

6. Due to Prohibition, temperance societies are held either in contempt, ridicule or fear, while our social service groups have, for the most part, limited their work to curative measures with acute alcohol problems.

Several states have now set up commissions to study and deal with the alcohol problem, and we feel that the results reported in England, Scandinavia and Switzerland should be considered in the overall approach. Mental illness, juvenile delinquency and criminality are, like alcoholism, partly derived from environmental situations, and also, like alcoholism, they are on the increase. We are not likely to see any decrease of the social tensions within the next few years. We are entering an era which will probably be more chaotic, disruptive and emotionally disturbing than we have ever known. Violent changes and dreadful physical and emotional conditions throughout the world will have to affect us in many ways.

Retrospectively we understand the effects of our national expansion, restlessness, heterogeneity, industrialism and historical growth on the incidence of alcoholism to be enormous, owing to mass and individual insecurity and change in nearly all spheres of life plus quantity and quality of mobile living.

Preventive measures on a broad basis should definitely, therefore, incorporate ways and means of helping to modify or change our social environment so that it will not tend to stimulate the production of anxiety and tension but rather will tend to provide relative security and support through healthy community living. Opportunities for such now exist in the mediums of parent-teacher association groups, adult education centers, civic organizations, and the like, but the general public is either uninformed or does not utilize these to the fullest extent. It is up to the leaders in all fields to act more vigorously to help bring a deeper participation and interest in such groups. Preventive measures must of necessity stress the recognition of early signs of emotional illness and provide facilities for prompt examination and treatment, as well as prophylaxis.

In specific reference to the problem of alcoholism, from the immediate practical point of view, we need to train more workers to treat the individual alcoholic addict; we need to set up more and more adequate facilities, such as hospital wards, psychiatric hospitals, reception centers associated with mental hygiene clinics at which patients and relatives could receive help through diagnostic, placement and treatment services being available.

We are on the road to achieving these goals and with the cooperation of all groups having the same purposes and with community and individual support and work we should accomplish some of our aims within the coming years.

Meanwhile it is definitely the obligation of all workers and educators to explain the fundamental facts of alcoholism to the community and to drive home over and over again that alcoholism is a symptom of a psychiatric disorder, illness or maladjustment; that the alcoholic addict cannot stop drinking at will and is different from other social drinkers; that he can be helped, treated and rehabilitated; that the alcoholic addict in contemporary America is partly a product

of our culture and its inherited and present strains and tensions, and that in addition to treating the alcoholic individual we must help reorient our culture and social ways of thinking and living to a more decent, vital and spiritually productive level.

SUMMARY

The nonpsychotic nondeteriorated prisoner who sincerely desires to rehabilitate himself has, we feel, a splendid opportunity to take advantage of modern scientific psychologic knowledge that will enable him, practically, to help himself and others in understanding that criminal behavior and alcoholism are not only waste products of a society that does not care about the individual's welfare but also of individuals who do not care about the welfare of society.

If he wants to, the prisoner can by his behavior do much to stimulate sound reforms in thinking about these very similar personality reactions—criminality and alcoholism—and to support sound ways of helping prevent their incidence in such large numbers; for, since truth is never hackneyed to those who desire truth, "Actions speak louder than words" and "As we would have others be and behave so should we behave and be." Therefore the prisoner who understands that his criminal acts were the result of emotional instability and poor integration of his personality assets that precluded his feeling and being a part of the social group should understand that the use of alcoholic beverages would definitely reactivate these disruptive conditions; and he should for his own sake keep in mind that:

1. His period of being on trial extends beyond the prison sentence and parole: he must be prepared to meet with rebuffs in a mature manner of tolerance and forgiveness.

2. He, as an individual, has physical, intellectual and emotional drives which he must learn to control if he is to have any measure of "happiness" or inner security.

3. The use of alcoholic beverages (including beer and wine) always tends to relax self control and to set free any underlying forces. Whether or not he feels that he has an alcohol problem, he should never drink again. From the down to earth point of view, he should recognize that the average man or woman naturally tends to be overcritical of the criminal, and a discharged criminal who is known to drink will necessarily be thought of with less confidence and more distrust than the known nondrinker. Conversely, the discharged prisoner who does not drink is given more moral support by the community, and life is made considerably easier for him. There is here a definite choice the prisoner himself can make between the relatively easy and the relatively hard way of readjusting to and being accepted by the community.

CONCLUSION

Alcoholism in America is a serious national health problem; the problem of criminality is closely associated in the personality field with alcoholism; neither the alcoholic addict nor the criminal (provided there are no organic or deterioration changes) should be viewed as hopelessly beyond rehabilitation. Society must assume its responsibilities on a realistic basis to help provide environments that do not tend to produce retarded or warped personalities; and individuals themselves must take some responsible purposive action along these lines and not, in an infantile manner, expect the community or the state to administer to all their wants and desires.

Many attempts have been made to administer penicillin effectively by mouth. Abraham and his co-workers,¹ in 1941 reported unsatisfactory results even when the penicillin was protected by a coating of phenyl salicylate but found that, when given through a duodenal tube, detectable levels were present in the blood for three hours. Herrell, Heilman and Williams² in 1942 stated that penicillin was destroyed by the acid of the stomach but that some absorption occurred when sodium bicarbonate was given conjointly. Powell and Jamieson³ also reported that penicillin cured staphylococcal infections in mice when given in combination with sodium bicarbonate. Rammelkamp and his co-workers,⁴ in two papers in 1943 confirmed the impression that oral administration was unsatisfactory, although duodenal absorption occurred, and showed that patients with achlorhydria absorbed the drug fairly satisfactorily. The Floreys⁵ tested cellulose hydrogen acetate phthalate as an enteric coating but found that, while penicillin could sometimes be demonstrated in the blood, reliable therapeutic levels could not be assured, and also that administration by duodenal tube was unreliable. In 1944 Free and his associates⁶ showed that, after large doses of penicillin by mouth, more antibiotic activity was demonstrable in the urine than when given together with sodium bicarbonate.

Libby⁷ early in 1945 demonstrated the protective property of cottonseed oil against destruction by gastric acid of orally administered penicillin. At about the same time several other promising reports appeared. Little and Lumb⁸ recommended giving penicillin with raw egg as a stabilizer after administration of sodium

bicarbonate. McDermott and his co-workers,⁹ using huge doses (350,000 units) of penicillin in water, achieved blood levels of 1 unit per cubic centimeter at one hour's time. Moses¹⁰ obtained therapeutic effects when penicillin was taken in high concentration (20,000 units per cubic centimeter), but estimations of the blood level were not made. György and his co-workers¹¹ administered penicillin with 1 to 5 Gm. of trisodium citrate, with the attainment of blood concentrations of 0.2 unit per cubic centimeter after one hour. Charney, Alburn and Bernhart¹² also used trisodium citrate and other gastric antacids and were able to obtain urinary excretions of 18 per cent of the dose administered. Burke, Ross and Strauss¹³ gave large doses (100,000 to 200,000 units) of penicillin in a double capsule, hardened by immersion in formaldehyde and alcohol, with resultant phenomenal levels of up to 10 units of penicillin per cubic centimeter of blood. Moldavsky and Hesselbrock,¹⁴ also using 100,000 unit doses, coated the penicillin capsules with phenyl salicylate and produced blood levels of 0.75 unit per cubic centimeter at the end of thirty minutes. Paul and his co-workers¹⁵ and Krantz, Evans and McAlpine¹⁶ used aluminum dihydroxyaminoacetate as an antacid, with doses of 100,000 units of penicillin, or more, and successfully cured gonorrhea. With the same adjuvant Krantz, Evans and McAlpine,¹⁶ using 100,000 units of penicillin, produced serum levels of 0.68 unit per cubic centimeter at three hours. Finally Loewe and others¹⁷ further explored the possibility of rectal administration with cacao butter suppositories containing up to 1 million units of penicillin. Levels of penicillin in the blood as high as 0.77 unit per cubic centimeter were obtained.

Our initial experiences¹⁸ with a wide variety of adjuvants and several enteric coatings suggest that there are three variables in the problem of the absorption of penicillin. The first is destruction by gastric acidity. The second is the rate of absorption from the upper bowel. Penicillin is so quickly excreted by the kidneys that absorption must be rapid if a measurable level is to be obtained in the blood. The third factor is destruction by penicillinase-producing organisms in the bowel.¹⁹ This appears to be less important than the other variables for peroral administration, since the flora in the upper intestine is probably sparse. Also absorption of penicillin occurs from ligated loops of colon in the rat,²⁰ although to a lesser extent than from the duodenum. Results to be published elsewhere²¹ show that in rabbits the same levels of penicillin in the blood follow injection of the agent into a branch of the portal vein as into an ear vein. This suggests that, if absorbed,

Technical assistance throughout was given by Doris W. Jenkins, Mary W. Cutting and Erl G. Woo.

From the Departments of Pharmacology and Therapeutics, and of Medicine of the Stanford University School of Medicine, San Francisco, and the Department of Urology, Permanente Foundation Hospital, Oakland, Calif.

Part of the penicillin was supplied by the Office of Scientific Research and Development from supplies assigned to the Committee on Medical Research for experimental investigations, recommended to the Committee on Chemotherapeutics and Other Agents of the National Research Council, and by a commercial laboratory in a study to determine toxicity and effectiveness.

given either in water or in a gelatin capsule, 3 of 6 subjects showed a blood level of 0.06 unit per cubic centimeter after one to one and one-half hours, while the other 3 had no measurable concentration. This showed that, although persons with anacidity might absorb penicillin, the levels that were obtained were not particularly high. Furthermore, other factors, such as absorption, must also be important, as some of the subjects failed to absorb it, even in the absence of acid.

Therefore, in six further trials, adjuvants were added to the penicillin to see if the absorption could be made more certain. A mixture of acetylsalicylic acid 1 Gm. with sodium bicarbonate 1 Gm. was used in four of the trials, with urea 0.6 Gm. and atabrine 0.1 Gm. in the other two, respectively. In all cases penicillin was absorbed, the average level in the blood at one to one and one-half hours being 0.06 unit per cubic centimeter.

Thus there is a further indication that destruction by acid, although perhaps it is of primary importance, is not the only factor limiting the usefulness of penicillin by mouth, and that the regularity of its absorption may be increased by adjuvants. This might be presumed to be particularly true in persons who have gastric acid, for even the best enteric coating is probably only a partial protection.

SINGLE TRIALS IN PERSONS WITHOUT GASTRIC ACHLORHYDRIA

An extensive survey of the absorption of penicillin in various combinations and with various enteric coatings was made in normal persons or patients without gastric achlorhydria. Most of the subjects were either fasting or at least two hours postprandial. The usual dosage of penicillin was 50,000 units, given in a size 00 gelatin capsule, although occasionally other dosages or forms of administration were used. The blood level of penicillin was usually estimated from three to four times, at one-half to one hour intervals. The maximum, which was usually at one hour, was the basis for comparison. Sodium penicillin was used throughout, except as noted. When it was thought that an adjuvant, also placed in the capsule, might destroy the penicillin, the penicillin was placed in a size 5 inner capsule. In many instances some form of enteric coating was applied to the outside of the capsule. These included "Enterab," a resin, dissolved in acetone, supplied by Abbott Laboratories, North Chicago, Ill.; a castor oil-shellac coating; solution of formaldehyde U. S. P. diluted 1:20 for five seconds followed by ethyl alcohol for five minutes; cellulose hydrogen acetate phthalate dissolved in acetone (hereafter called "cellulose"); a mixture of equal parts of the "Enterab" and "cellulose" solutions (hereafter called "Enterab-cellulose"); and "Seal-Ins," supplied by the "Seal-Ins" Laboratories, Los Angeles.

The results are grouped in the following five sections:

1. *Penicillin Without Adjuvant or Enteric Coating.*—Penicillin in a dose of 50,000 units was given in a single gelatin capsule to 1 normal subject and in a dose of 100,000 units to 3 others, with the following blood levels at one-half hour respectively: 0.12, 0.06, 0.06 and 0.03 unit per cubic centimeter. These levels are easily in the therapeutic range and support the statement of McDermott and his co-workers²⁴ that penicillin in water, in large doses, is readily absorbed.

To test the claim of Moses¹⁶ that small amounts of penicillin in concentrated solution would be absorbed, 50,000 units of penicillin in 2.5 cc. of water was held in the mouth for thirty minutes, and on two subsequent occasions this amount was slowly swallowed. At no time could penicillin be found in the blood. As the latter two trials are in a sense an extension of the tests already described, it is seen that there is considerable variation in the absorption of unprotected penicillin.

2. *Penicillin Mixtures Not in Capsules.*—Seven trials on 4 normal persons were made with mixtures of penicillin and an alkali, adsorbent or antiseptic, as follows: 20,000 units of penicillin with 30 cc. of aluminum hydroxide gel; 20,000 units with 15 Gm. of sodium bicarbonate plus 5 Gm. of charcoal; 20,000 units with 30 cc. of cream; 80,000 units with 15 Gm. of silica gel; 50,000 units with 1 Gm. of sodium alkyl sulfate; 50,000 units with 50 mg. of gentian violet, and 50,000 units with 10 cc. of ethyl alcohol. In no case was penicillin demonstrable in the blood.† This confirms the previously reported²¹ poor success with large amounts of antacids given conjointly.

3. *Penicillin in Enteric Coated Capsules.*—Six trials in 5 normal persons were made in which the penicillin was protected by enteric coatings as follows: 20,000 and 50,000 units of penicillin in a gelatin capsule coated with "Enterab"; 20,000 units coated with castor oil shellac; 20,000 units with "Seal-Ins"; 20,000 units with "cellulose," and 50,000 units with "Enterab-cellulose." Only with the last preparation was absorption measurable, 0.03 unit per cubic centimeter of blood appearing at one hour and lasting for two and one-half hours. These results are in agreement with the early reports²⁵ claiming that enteric coating gave unsatisfactory results but are decidedly inferior to the results obtained with formaldehyde hardened¹⁵ and phenyl salicylate coated¹¹ capsules reported recently. As shown in a later section dealing with continued administration, we have been unable to confirm the high absorption reported by Burke and his co-workers,¹³ although our penicillin dosages were somewhat smaller.

4. *Penicillin in Enteric Coated Capsules, with Adjuvant Given Separately.*—Eight trials were made on 3 normal persons and 1 patient with the penicillin enclosed in an enteric coating and, separately, an adjuvant intended to promote absorption or protect the penicillin (table 1). A mixture of acetylsalicylic acid and sodium bicarbonate was moderately effective. Sulfadiazine also produced a moderate blood level, but part of this may have been due to the antibacterial action of the sulfonamide itself.

5. *Penicillin with Adjuvants in Capsules, Usually Enteric Coated.*—Most of the single dose trials which were made belong in this category.† Penicillin was combined with several general types of agents, namely antiseptics, surface tension reducers, organic solvents,

salicylates, protoplasmic poisons, a natural oil, alkalis and miscellaneous agents. Certain of the adjuvants obviously could be classified under more than one type. In the majority of trials the capsules were enteric coated. A total of 152 tests in over 50 normal subjects or patients was made, with results shown in table 2.

Of the antiseptics only methenamine was promising, and of the surface tension reducing agents only sodium alkyl sulfate and aerosol OT10 gave any absorption. This suggests that bacterial destruction is unimportant in the region where penicillin is released.

The organic solvents were more effective.† Ethyl alcohol and acetone, in particular, gave occasionally good, though erratic, absorption. Triisopropanolamine, however, gave highly consistent and fairly adequate blood levels. In a dose of 0.8 cc. it often produced some nausea, but in doses of 0.5 cc. or less this was not present. The highly alkaline nature of triisopropanolamine (pH 11) suggested that perhaps the effect was simply due to this factor and not to an effect on intestinal permeability. Triisopropanolamine slowly destroys penicillin when the two agents are in contact, necessitating a separate, inner capsule for the penicillin. Whether the alkalinity of this amine is responsible for the destruction or some other change in the penicillin was not determined. Inner capsule protection for solid alkalis, such as trisodium citrate, did not appear to be necessary.

† A comparison of sodium penicillin with calcium penicillin was made in the triisopropanolamine series. The average blood level in twenty trials with sodium penicillin was 0.047 unit per cubic centimeter; with calcium penicillin in ten trials it was 0.018 unit per cubic centimeter. Because of the inferior showing of the calcium salt, only the sodium salt was used in the remainder of the trials.

† Acetylsalicylic acid, especially when combined with sodium bicarbonate, was moderately effective in promoting the absorption of penicillin, but other salicylates were ineffective.

† The protoplasmic poisons, such as quinine, and several miscellaneous agents were relatively ineffective.

† In spite of the reported⁷ efficacy of cottonseed oil, we obtained no absorption when the dose of penicillin was the usual 50,000 units, but 100,000 units gave satisfactory levels.

We were able to confirm, however, reports²⁶ stating that antacids, in particular trisodium citrate, were effective adjuvants. As sodium carbonate is a still stronger alkali, comparisons were made with this salt, without any significant difference from the sodium citrate.

The enteric coatings varied considerably in their action. With a large dose of penicillin (100,000 units) they may contribute little or nothing to the ultimate blood level. "Enterab" protected capsules (as we made them) usually disintegrated in the stomach (fluoroscopic evidence) about twenty minutes after ingestion, while uncoated capsules broke within ten minutes. "Cellulose" protected capsules were more durable and often did not break for one or two hours, and then not in the stomach. This would seem to be the exact type of protection theoretically desirable, but the results were uniformly less satisfactory than with a less resistant coating. Capsules coated with a mixture of equal parts of "Enterab" and "cellulose" usually disintegrated in the stomach or duodenum within thirty to forty-five minutes after ingestion. With continued administration, described in the next section, enteric coatings appeared to add slightly to the effectiveness of peni-

* Averages given in parentheses

cillin-alkali combinations but prevented some gastric distress which the stronger alkalis otherwise caused.

The great number of unsuccessful trials, in spite of the fact that unprotected penicillin alone may be absorbed, requires explanation. Possibly some of the adjuvants destroy the drug, but this can hardly be generally true. Our trials with penicillin alone were mostly with higher doses, and it is probable that there would be many failures with single doses of 50,000 units of penicillin.

Many of the trials which failed to produce a demonstrable blood level gave urinary levels of several units per cubic centimeter. This strengthened our conviction that it was important to accelerate the absorption of penicillin in order to keep ahead of the urinary loss.

REPEATED ADMINISTRATION OF CAPSULES OF PENICILLIN

The single trials of penicillin in various combinations discussed in the previous section indicated which should be tried on repeated administration. The latter means of testing is more crucial, as in a test lasting over many hours the effects of food, state of mind, accumulation of the drug and cumulative toxicity of the adjuvant may be more easily evaluated.

Therefore the more promising agents and combinations were tried on repeated administration in patients. Of the 77 subjects, all but 6 were males, most of them with gonococcal infections. The usual course of administration lasted twenty hours, with the penicillin capsules being given every two hours. Blood was taken for the estimation of penicillin one hour after each dose. The total urine for the twenty hours of the trial, plus an additional four hours, was also collected and its penicillin content determined. The results are summarized in table 3, in which groups of comparable trials are averaged separately.

When penicillin was given without adjuvants, except enteric coating, in ten repeated administrations to 10 patients, the average blood level for the one hundred determinations was 0.015 unit per cubic centimeter and the average urinary recovery 5 per cent of the doses ingested. When no enteric coating was used, the average blood concentration was 0.012 unit per cubic centimeter, with "Enterab-cellulose" it was 0.020, with "cellulose" 0.004 and in a single trial with formaldehyde hardening 0.025. Thus, although there is considerable variation, with some total failures of absorption, it is seen that penicillin is absorbed moderately well in these doses (50,000 units) without adjuvants or enteric coatings and that a good enteric coating ("Enterab-cellulose" or "formaldehyde hardening") increases the degree of absorption, while too resistant a coating ("cellulose") interferes with absorption. It may be concluded that any combination containing 50,000 units of penicillin must produce an average blood concentration above 0.02 unit per cubic centimeter to surpass in efficiency the simple combination of penicillin and a light enteric coating.

The absorption in the 2 patients with gastric anacidity are revealing in showing that acidity alone is not the only determining factor, thus confirming the individual results in a previous section. In 1 patient the excellent absorption is according to expectation, while in the other the low values probably indicate poor penetration through the intestinal wall.

Results in 12 patients with zephiran, acetylsalicylic acid with sodium bicarbonate, ethyl alcohol, acetone, acetylsalicylic acid with methenamine, and cottonseed oil were irregular, and not outstanding. While fair absorption was occasionally demonstrated, the average

values were lower than those with penicillin and a simple enteric coating. This may indicate that these agents actually interfere with the absorption of, or destroy, penicillin, but to us it seems more likely, considering also the early results with single doses, that in a larger series some of these combinations would prove to enhance absorption minimally. However, this is obviously of no practical help. We also have the impression, although confirmation is impossible, that the penicillin currently available (May 1945) produces somewhat higher blood levels than that of a year ago. Our trials with penicillin in simple enteric coatings have been recent, for the most part, and therefore may gain in comparison to trials of several months ago. Although the various brands have differed greatly in color and potency per unit weight, we have not detected any particular difference in the results of oral administration. The following brands have been used: Wyeth, Cutter, Pfizer, Lilly, Burroughs and Wellcome, Squibb, Commercial Solvents and Schenley.

The three final combining agents, triisopropanolamine, trisodium citrate, and sodium carbonate, gave much more satisfactory results, easily of clinical value.

Triisopropanolamine was used on 29 patients, and the conclusions are therefore based on nearly 300 blood estimations. The larger dose of the adjuvant, 0.8 cc., used initially, was discontinued because of frequent nausea and vomiting, which did not occur with one-half this dose. The addition of 0.4 cc. propylene glycol to the smaller dose of triisopropanolamine did not enhance the action and was therefore also discontinued.

The "Enterab-cellulose" coating was used in nearly all the trials, particularly as in single dose tests this appeared to lessen the likelihood of gastrointestinal irritation.

Taking only the results with the smaller dose of triisopropanolamine and with freshly made capsules, or those in which the penicillin was protected, the average blood concentration in six trials with 50,000 units of penicillin was 0.038 unit per cubic centimeter, or nearly twice that obtained with the use of the simple enteric coating alone. With 25,000 units of penicillin in each dose the average in five trials was 0.013 unit per cubic centimeter, showing that the larger dose enhanced the degree of absorption. In six trials with 100,000 units the average blood concentration was 0.049 unit per cubic centimeter, a value less than would have been expected if the blood concentration rose proportionately to the increase in dose. This suggests that a dose of 50,000 units may give the maximal relative absorption. Further trials would be necessary to establish this conclusively, as the urinary excretion from 100,000 unit doses was about twice that with 50,000 unit doses. The high variability of the antibiotic activity of the urines, however, precludes their acceptance as reliable criteria of absorption. Very likely the rate of destruction of penicillin in the urinary tract, and after collection of the specimen, depends on variables such as infecting or contaminating organisms and the temperature. We were unable to correlate the content of penicillin with the p_H of the urine.

The systemic toxicity of triisopropanolamine is negligible. It has been used for several years as an ingredient in sobisminol mass, a bismuth product for oral treatment in syphilis. Considerably more labor, however, is involved in preparing capsules in which the penicillin must be enclosed in a second, smaller capsule than in those combinations in which it can be freely mixed with the adjuvant.

Trisodium citrate as the adjuvant, in eight trials with 50,000 units of penicillin, gave an average blood level of 0.021 unit per cubic centimeter, or about one-half that when triisopropanolamine was used. In three trials with 100,000 units, however, the average was 0.055 unit per cubic centimeter, or slightly greater than with triisopropanolamine. A similar result was obtained with sodium carbonate, which is a stronger alkali than sodium citrate, more closely resembling triisopropanolamine in this respect. The average concentration after 50,000 units with sodium carbonate was 0.024 (five trials) and with 100,000 units 0.058 (three trials). Here the trend, at least, was toward doubling the blood concentration when the dose was doubled.

A comparison, then, of the results obtained with the three agents triisopropanolamine, trisodium citrate and sodium carbonate shows them to be of about equal efficiency in promoting the absorption of penicillin. With 50,000 units of penicillin, triisopropanolamine appears to give the best results, but with 100,000 units this superiority is not evident. This similar efficacy and the common characteristic of alkalinity suggest that it is solely this factor which is of importance in the action of these adjuvants. If triisopropanolamine has a direct action on the intestinal mucosa to increase permeability, other than that which any alkali might possess, it cannot be of outstanding importance. It is possible than any alkali, in addition to neutralizing acid, might effect intestinal permeability, but this action would not appear to be great.

The addition of small amounts of cottonseed oil to any of the three adjuvants just described did not give any great difference in absorption. Although it was felt that with penicillin alone, and with most adjuvants, a light enteric coating improved absorption and decreased irritation, this was not evident with trisodium citrate. This is important when penicillin capsules are to be made extemporaneously, as the process then becomes quite simple, as follows: Pack one-half the contents (50,000 units), or the entire contents (100,000 units), of a commercial vial of penicillin in a size 00 capsule, and then fill the capsule with trisodium citrate. Administer such a capsule every two hours.

RESULTS IN THE TREATMENT OF GONORRHEA

Fifty-three of the 77 patients treated with repeated doses of penicillin (table 3) had acute gonorrhea. The remainder suffered from various diseases (pyogenic dermatitis, prostatitis, cystitis, infected wounds, and so on), in which exact assessment of cure or improvement was impossible. Of the 53 patients with acute gonorrhea 38, or 72 per cent, were cured, as judged by three negative prostatic cultures at weekly intervals after treatment. Of the failures 4 were so counted because of inadequate follow-up. Of the remaining 11 failures 4 were the patients whose individual doses were 25,000 units (a total of 250,000 units for the entire course of treatment). Obviously this dosage is inadequate, although by intramuscular injection cure would seem assured. The remaining 7 failures were all with individual doses of 50,000 units (total 500,000 units for the course) and consisted of 1 with acetylsalicylic acid and sodium bicarbonate combination, 2 with triisopropanolamine (but penicillin not protected from adjuvant), 2 with sodium carbonate (but heavy cellulose coating on one), 1 with cottonseed oil and 1 with trisodium citrate.

Thus it is apparent that a total dose of one-half million units, prepared in one of the superior combinations, may be expected to produce a high incidence of cure in acute gonorrhea in the male, probably 90 per cent.

COMMENT

A survey of the problem of peroral absorption of penicillin shows that, although destruction by gastric acid, lack of intestinal absorption and destruction in the bowel by penicillinases are all theoretically of importance, the available adjuvants act primarily only on the first mechanism. Three alkalis, namely, triisopropanolamine, trisodium citrate and sodium carbonate, are of about equal effectiveness and improve the absorption of penicillin over that obtained by other methods, including penicillin without adjuvants. These alkalis are also more effective than any of several enteric coatings, although a light enteric coating may improve results slightly. By means of such combinations the absorption of penicillin by normal persons becomes approximately that obtained in persons with gastric achlorhydria. This suggests that any great improvement over these results will come, not with another antacid, but with an agent which promotes the penetration of the drug through the intestinal mucosa. At present the production of such an effect is speculative. Quinine, methenamine, the salicylates and possibly triisopropanolamine or other alkalis may depress the mucosal cells directly and so be conducive to such an effect. The organic solvents may affect the lipoids of the cell surfaces, possibly by extracting or altering certain elements which would decrease their normal protective power. These are only suggestions, as little is known concerning fundamental factors influencing permeability through living membranes.

The extremely large doses, i. e. 500,000 to 1,000,000 units, which have been used by others were not tried because of expense. It has been disappointing that our best results are greatly inferior to some reported by others, notably Burke and his associates.¹³ We are at a loss to explain this discrepancy.

Excellent results were produced in gonorrhea by the best preparations. Oral therapy for this disease may be criticized as being subject to unreliability on the part of the patient and as masking coincident syphilis by inadequate treatment. Gonorrhea was chosen, however, as large numbers of patients were available, relatively exact diagnosis and proof of cure may be established, the organism was highly susceptible, and it was a disease in which inadequate treatment would not immediately threaten life. With the ordinarily effective total dose of one-half million units, expense (about \$5 at present) ceases to be an important factor in limiting oral treatment of gonorrhea. However, the ultimate desirability of oral medication in gonorrhea remains undetermined.

CONCLUSIONS

1. Extensive trials of the administration of penicillin by mouth, with various enteric coatings and adjuvants to protect the penicillin or promote its absorption, resulted in the following useful combinations: mixtures of penicillin with triisopropanolamine, trisodium citrate or sodium carbonate enclosed in a res-in-cellulose plastic enteric coating.

2. When the dose of penicillin was 50,000 units, administered every two hours for ten doses, these

superior combinations produced penicillin blood concentrations of from 0.02 to 0.05 unit per cubic centimeter.

3. Fifty-three cases of acute gonorrhea were treated with several of the most promising combinations, with cures in 38, or 72 per cent.

4. Treatment of infections with highly susceptible bacteria by orally administered penicillin appears to be feasible.

TOURNIQUET PARALYSIS

ANALYSIS OF THREE CASES OF SURGICALLY
PROVED PERIPHERAL NERVE DAMAGE FOLLOWING
USE OF RUBBER TOURNIQUET

MAJOR I. JOSHUA SPEIGEL

AND

LIEUTENANT COLONEL PHILIP LEWIN
MEDICAL CORPS, ARMY OF THE UNITED STATES

Paralysis of a peripheral nerve following the use of a rubber tourniquet for surgical hemostasis is not an infrequent occurrence. A review of the literature, however, reveals few reports of such lesions. This is probably due to the fact that the vast majority of such cases show only an evanescent paralysis with involvement lasting a few days or weeks, followed by complete remission of symptoms. This deduction is verified by our own experience and that of the numerous surgeons with wide experience in the use of the tourniquet.

The first available report is that of Montes,¹ who in 1888 described permanent peripheral nerve paralysis as a result of the use of a tourniquet. The exact length of time of follow-up is not known. The next item in the literature is a case report by J. J. Putnam² in 1888 before the Boston Society for Medical Improvement. He described complete paralysis of the nerves of the arm following the application of a rubber tourniquet during a surgical procedure on the hand. The patient had a reaction of degeneration in the involved muscles. It was Putnam's opinion that "not only was degeneration present at the site of the lesion but that it traveled distally along the nerve to the involved muscle, inciting a subacute inflammation in the muscle." Further details are not reported by this author.

The largest series of similar cases is that collected by Eckhoff,³ who described 14 cases of tourniquet paralysis with varying degrees of permanence and severity, none of which were surgically explored. None of this writer's cases were permanently paralyzed. Ten of his cases were cured in three months, 3 cases were cured in five months and 1 case improved in six months. All received intensive physical therapy. In that writer's experience the radial nerve was the most frequently involved, although in a fair proportion of cases the median or ulnar nerve was involved. An interesting observation in some of his cases was the return of voluntary power before the return of faradic current response. Robb⁴ reported his findings in tourniquet paralysis of all the main nerve trunks of the arm. Treatment consisted of intensive physical therapy, which was followed in three months by complete

recovery. This author makes the statement that, in general, recovery takes place in from one to six months.

Burman⁵ in 1940 was the first to report a case of tourniquet paralysis in which the involved nerve (sciatic) was explored surgically. As in 1 of our cases the tourniquet was applied during the course of a meniscectomy of the knee. Exploration at the level of the tourniquet revealed that the "medial portion of the sciatic nerve was flattened and compressed for a distance of 1 inch, and the lateral nerve was covered by a small organizing fibrinous hemorrhagic exudate." Neurolysis was performed, and in nine months complete recovery had taken place.

It becomes evident, therefore, that few cases of permanent paralysis secondary to the use of a tourniquet have been reported in the literature. All of Eckhoff's cases were cured in a few months, as was also the case of Robb. Burman's case improved in nine months after a neurolysis had been performed. Specific details regarding Montes' and Putnam's patients are not available, but it is to be presumed that they were permanently paralyzed. Thus, of the 18 cases noted in the literature, 16 were not permanent, the majority being less than three months, and 2 cases were presumably permanent.

One of us (I. J. S.) had under his care during the last eighteen months 970 peripheral nerve injuries, almost all of which were battle casualties. Among this group there were 3 cases of permanent paralyses secondary to the use of the tourniquet. In view of the more or less general use of a tourniquet to produce an avascular surgical field and the relative infrequency of this complication, these cases are presented for analysis.

REPORT OF CASES

CASE 1.—A sergeant in the infantry, aged 38, with no significant episodes in his past history, was struck in the left midforearm by land mine fragments on Nov. 6, 1943. A compound comminuted fracture of the radius resulted, but there was no evidence of paralysis. On November 7 the wound was debrided, the operation being performed with a tourniquet of rubber tubing applied at about the junction of the lower and middle thirds of the arm. The duration of the operation is not definitely known, but the patient believes that it took one and one-half hours. A cast was immediately applied. It was not until December 15, on removal of the cast, that a complete wrist drop was noted. The wounds and fracture healed well, but there was no evidence of improvement in the nerve deficit.

Physical examination revealed well healed wounds on the dorsal and volar surfaces of the middle third of the forearm, with complete paralysis of the extensor muscles of the wrist, fingers and thumb. There was also complete absence of brachioradialis muscle function, pronounced weakness of supination, paralysis of the abductors of the thumb and a small patch of diminished sensation over the dorsum of the first interosseous space.

Although the wound was in the midforearm, tourniquet paralysis was suspected because the brachioradialis and supinator paralysis placed the level of the lesion above the elbow. Accordingly, on April 26, 1944 the radial nerve was explored in the arm from the point where it pierced the lateral intermuscular septum to its position between the tendon of the biceps and the belly of the brachialis muscle. On thus exposing the nerve in the lower third of the arm over a distance of 6 cm. (fig. 1) the radial nerve was noted to be less than half its usual diameter. Along this area of diminished diameter, at irregular intervals, were six firm nodules occupying almost the entire thickness of the nerve. Each nodule was about the

1. Montes de Ota, F.: Parálisis permanente producida por la isquemia quirúrgica, *Independ. med. México* 1: 35, 1880.

2. Putnam, J. J.: Peripheral Paralysis Following Use of a Rubber Tourniquet, *Boston M. & S. J.* 119: 107, 1883.

3. Eckhoff, Nils L.: Tourniquet Paralysis, *Lancet* 2: 343, 1931.

4. Robb, Douglas: A Case of Tourniquet Paralysis, *New Zealand M. J.* 32: 203, 1933.

size of a split pea and had the characteristic consistency of a neuroma. Electrical stimulation above the most proximal nodule yielded no muscular response, and saline solution when injected into the neuroma would not flow above or below the pathologic area. In view of the long area of nerve that was damaged, resection and suture of this area was considered unwise and

Fig. 1.—Surgical exposure of the radial nerve in case 1, revealing the multiple neuromas in the nerve below the area of tourniquet application.

the wound was closed. It healed well. Because of the findings at operation, it was decided that the lesion was irrevocable and tendon transplantation was performed two months later. The details of the last operation and subsequent course are not available to us.

CASE 2.—A private in the armed forces, aged 25, with no abnormalities in his past history, began early in 1943 to experience pain in the left knee with tenderness anterolaterally over the knee joint. He was found to have the classic findings of a ruptured meniscus. On Jan. 26, 1944 in an overseas hospital meniscectomy was performed on the left knee. The operation lasted approximately one and one-half hours and during the entire operation a tourniquet (probably rubber tubing) remained in force high up on the middle third of the thigh. Immediately following operation a full length leg and thigh cast was applied to a point just above the ankle. Because of some discomfort at the ankle, the cast was bivalved. Immediately on removal of the cast the patient noted a complete foot drop with numbness on the dorsum of the foot, particularly on the adjacent sides of the great and adjoining toes, and weakness of plantar flexion of the ankle. For three months following this there was some improvement in function of plantar flexion at the ankle joint, but for about three months prior to admission to the service of one of us (I. J. S.) no noticeable improvement took place.

Physical examination on admission to the hospital on June 16, 1944 revealed a well healed surgical incision 3 inches long on the medial side of the left knee. There was complete foot drop on the left side, with paralysis of the dorsiflexors of the toes and evertors of the foot. Plantar flexion and inversion were normal. Hyperesthesia and hypalgesia were present on the lateral aspect of the leg and the dorsum of the foot and toes.

On July 6 the left sciatic nerve was exposed from the gluteal fold to the head of the fibula (fig. 2). In the middle third of the thigh the nerve was seen to be surrounded by scar tissue and was remarkably thinned out, especially its common peroneal component. Over a distance of 4 inches the common peroneal portion of the sciatic nerve was firm, hard and narrowed to one fourth of its normal diameter. Saline solution would not flow above or below this area when injected, and there was no response to electrical stimulation. The tibial portion of the nerve appeared quite normal. The common peroneal nerve at the head of the fibula showed no evidence of injury from the cast. Since the defect was too large to bridge, the scar

tissue was cleared away and the wound closed. There was no postoperative change in symptoms. The patient was followed for four and one-half months postoperatively with no change in symptoms. Following this he was discharged from the service and further check-up is therefore not available.

CASE 3.—A sergeant in the Tank Corps, aged 40, slipped during a bombing attack on his ship and fell three decks to the hold of the ship, sustaining a comminuted fracture of the head of the right radius. There was no evidence of involvement of the radial nerve. On Nov. 26, 1943 he was operated on because of the displacement of the head of the radius. At operation pronounced comminution of the head of the radius was seen, and one section was displaced beyond the confines of the orbicular ligament and the capsule of the joint. The head of the radius was excised, but some fragments still remained. Following operation there was no evidence of radial nerve involvement. However, since limitation of movement at the elbow joint persisted, on June 6, under intravenous pentothal sodium anesthesia, the joint was reexplored, a loose body removed and the elbow manipulated to overcome some adhesions. A tourniquet was applied at the beginning of the operation and remained on for approximately fifty-five minutes. Immediately following the operation a complete wrist drop was present and has persisted to the present time.

On September 3 he was admitted to the Mayo General Hospital and examination revealed a well healed scar on the lateral aspect of the right elbow joint. He had slight tenderness over the normal area of the head of the radius. There was symmetrical atrophy of the entire right upper extremity, most pronounced over the dorsum of the forearm. About 20 per cent loss of power of the forearm supinators and a similar weakness in the brachioradialis muscle were present. There was about a 30 per cent loss of power in the extensors of the wrist, along with complete paralysis of the extensors of the fingers and thumb. Active abduction of the thumb was lost. An area

Fig. 2.—Surgical exposure of the sciatic nerve in case 2, revealing thinning of the nerve below the level of tourniquet application, most severe in the common peroneal portion. A good deal of scar tissue is evident around the nerve.

of hypalgesia was noted over the dorsum of the first interosseous space, the thumb and the proximal phalanx of the index finger. Hypalgesia was also noted over the dorsolateral aspect of the forearm.

There was an area of brown discoloration around the lower third of the arm, where, apparently, the tourniquet had been applied.

October 13 the radial nerve was exposed by a lateral incision extending from 1 inch above the area where the tourniquet had been applied to the head of the radius. At points 0.5 cm. above and 1 cm. below the area of application of the tourniquet two firm nodules, each about the size of a split pea, could be palpated (fig. 3). They occupied about three fifths of the diameter of the nerve. Below these neuromas the radial nerve was narrowed to about one half its usual size in that location. The nerve was traced to its point of division and beyond, but no evidence of injury to the nerves at the site of previous operation was found. Small bands of adhesions surrounding the neuromas were separated. Saline solution was injected above and below the neuromas and flowed beyond each, of these into the uninvolved portion of the nerve. Since the patient still had some brachioradialis, supinator and extensor carpi muscle function, resection of the neuromas was considered unwise. The cutaneous branch of the musculocutaneous nerve was visualized but appeared normal. The morning following the operation the patient noted increased power in the brachioradialis and extensors of the wrist. He noted also improvement in sensation over the dorsum of the first interosseous space, the dorsum of the first phalanx of the index fingers and the dorsal surfaces of the thumb. Following this no further improvement was noted in the patient's symptoms over a period of four and

Fig. 3.—Surgical exposure of the radial nerve in case 3, revealing the two neuromas present in the nerve just at the site of tourniquet application. Note the thinning of the nerve below the neuromas.

one-half months. Since he did not desire tendon transplant, he was discharged from the service and has not since been heard from.

COMMENT

Allen,⁶ from a series of experiments, comes to the conclusion that one of the main causes of death of a nerve following the use of a tourniquet is necrosis of nerve fibers from direct pressure at the tourniquet site. Another important factor, according to Allen, is local asphyxia, and experiments to bear this out are mentioned. In these experiments the factor of local tourniquet pressure was excluded and organic destruction of the nerve fiber still took place after from one to several hours following ligation of the main vessels of the limb. According to him, narrow rubber bands or tubes are less harmful and painful than broad tourniquets. His reasons are logical—a wide tourniquet at the same pressure as a narrow tourniquet is pressing on more surface than the narrow tourniquet and therefore can do more harm. In actual practice, however, one of us (P. L.) has noted that it is less harmful to use a broad tourniquet, the explanation being that a force applied over a greater surface is less harmful than an equal force applied over a smaller surface.

6. Allen, F. M.: The Tourniquet and Local Asphyxia, *Am. J. Surg.* 41: 192, 1938.

Denny-Brown and Brenner⁷ believe that the effect of pressure on a nerve is entirely an ischemic phenomenon. The effect of pressure on conduction is graded by these authors as follows:

1. Nil.
2. Paralysis with rapid complete recovery on release of pressure.
3. Paralysis with delayed recovery without degeneration.
4. Complete anatomic lesion with degeneration.

In their experiments on the effect of pressure on conduction in peripheral nerves, Bentley and Schlapp⁸ postulate a critical value of 130 mm. of mercury applied over a period of two to three hours for the production of nerve block. They state also that the time taken for the establishment of nerve block by direct pressure is much longer than that observed in ischemia. These authors stress the fact that pressure block has different characteristics from block due to ischemia and that the time taken for the establishment of nerve block by direct pressure is much longer than that observed in ischemia.

Biopsies of the nerve lesions seen in the 3 cases reported here were, of course, not taken because nerve suture was not surgically feasible, and possible return of function would have been jeopardized. The exact nature of the pathologic involvement is therefore not known. There was no question, however, about the presence of intraneural scar and neuromas in all the cases by palpation of the lesion. The only apparent causes for this involvement would therefore appear to be either pressure necrosis at the site of tourniquet application with fibrosis and neuroma formation or ischemia below the site of application of the tourniquet, death of the ischemic portion of the nerve, fibrosis and neuroma formation. Whatever the cause, however, the end result in all 3 cases was fibrosis and neuroma formation.

The radial nerve is more frequently involved in tourniquet paralysis because of its long course in direct contact with the humerus, rendering it particularly vulnerable to compression between the bone and the tourniquet. The sciatic nerve is, of course, less vulnerable but still is not immune, since there is no great abundance of muscle present to act as a cushion between it and the femur.

The median, ulnar and femoral nerves, by virtue of their more superficial positions and the heavy muscular pads between them and bone (at the usual tourniquet sites), are less frequently involved.

BRIEF COMMENT ON CONSTRICTORS

A bloodless field is vital in certain surgical procedures on tendons, bones and joints. It aids materially in accomplishing precision technic with the greatest speed, minimal loss of blood and minimal danger of infection, besides substantially reducing the possibility of fat embolism in operations on the long bones.

The main type of constrictors are:

1. The Martin bandage, a pure para-elastic rubber bandage obtainable in sizes ranging from 2½ inches by 9 feet to 3 inches by 12 feet.
2. The Esmarch band, a flat piece of heavy rubber about 1 inch wide and ¼ inch thick, with a metal chain at one end and a metal hook at the other.
3. The Campbell-Boyd pneumatic apparatus.
4. Rubber tubing and a clamp.

7. Denny-Brown, D., and Brenner, C.: Paralysis of Nerve Induced by Direct Pressure and by Tourniquet, *Arch. Neurol. & Psychiat.* 1: 51 (Jan.) 1944.

8. Bentley, F. H., and Schlapp, W.: Experiments on the Blood Supply of Nerves, *J. Physiol.* 102: 62, 1943.

It is recommended that any type of constrictor other than the Campbell-Boyd type be applied over a towel. The limb should be rendered bloodless by first elevating it for two minutes. A Martin bandage is then applied with each layer covering one edge of the preceding layer, extending from the tips of the toes more than half way up the thigh in the lower extremity and the arm in the upper extremity. Following this procedure, the constrictor is applied. The constrictor should be removed within an hour if feasible. In longer operations it is advisable to release the constrictor for a few moments and then renew the constricting force. In tendon procedures on the forearm and hand it is recommended that the tourniquet be released every forty-five minutes. Following the final removal of the tourniquet, the limb should be gently massaged in order that the blood vessels whose walls have been compressed may resume their patency.

It is our opinion that the use of the Campbell-Boyd pneumatic constrictor is attended with the least danger to vessels and nerves. It can be inflated and deflated without danger to sterile drapes and it allows for an even pressure exactly determined and distributed over a large area. Its manufacture is easy and has been adequately described.⁹ For an adult of average size, 15 pounds of pressure for the lower extremity and 10 pounds for the upper extremity are the maximum. The pressure for children is proportionately lower.

CONCLUSIONS

1. Severe damage of peripheral nerves can occur as a result of application of a rubber tourniquet for surgical ischemia.

2. Factors involved in the production of the paralysis are (a) pressure necrosis at the site of tourniquet application, with fibrosis and production of neuromas, (b) ischemia below the site of application of the tourniquet with death of the ischemic portion of the nerve, fibrosis and production of a neuroma in continuity, and (c) a combination of the foregoing two situations.

3. The radial and sciatic nerves are the most vulnerable to tourniquet paralysis.

4. Every case of tourniquet paralysis of a peripheral nerve immediately on its discovery should receive intensive physical therapy over a period of eight to twelve weeks. If, at the end of this time, no appreciable return of function is evident, surgical exploration of the involved nerve should be performed and a neurolysis or even neurorrhaphy (if feasible) should be attempted.

5. The Campbell-Boyd pneumatic constrictor appears to be the most efficient and least harmful of the constrictors.

Psychologic Experiments with Alcohol.—The most important conclusion that may be drawn from psychological experiments with alcohol—and these include many experiments which have not been described here—is that the various effects studied showed that alcohol is a depressant, not a stimulant. It affects first the higher brain centers which control the voluntary behavior and emotions, while the lower centers which control such vital functions as breathing are affected only in severe intoxication. Briefly, alcohol acts in the same way as the well known anesthetics. Since it is an anesthetic, one can correspondingly predict its effect in small and large quantities on efficiency on the one side, and on sedation and relaxation on the other side.—Jellinek, E. M., in *Alcohol, Science and Society*, New Haven, Quarterly Journal of Studies on Alcohol, 1935.

THE LIMITATIONS OF PENICILLIN IN TREATING EMPYEMA

J. KARL POPPE, M.D.

ST. LOUIS

Recently several papers have appeared which have emphasized the ability of penicillin to prevent the development of empyema. In the issue of *THE JOURNAL* of June 23 three papers appeared by Healy and Katz, by Rudensky, Sprong and Woods and by Hirshfeld, Buggs, Abbott and Pilling which stressed the value of penicillin in this respect.

My purpose in this paper is to point out not only the value but also the limitations of penicillin in the prophylactic treatment of empyema and stress the need for surgical drainage of established empyema. Penicillin has undoubtedly proved of great value in preventing empyema when it is administered in large quantities during the incipient stages, before frank pus has formed. This is especially true of postpneumonic pleural effusions, particularly of the pneumococcal variety, as indicated by the several favorable reports in the literature. Tillet, Chambier and McCormack¹ report 8 pneumococcal infections of the pleural space in 7 of which surgical drainage was avoided, although 1 required a thoracotomy and one was left with an unexpandable lung. Bennett and Parkes² report 4 cases. One sterile pleural effusion associated with a staphylococcal pneumonia was thought to represent an aborted empyema. Two pleural effusions containing streptococci were sterilized and resorbed before becoming established empyemas, and 1 staphylococcal empyema in a baby was followed for ten days after its apparent disappearance. Butler, Perry and Valentine³ report sterilization of the pleural fluid in 17 cases within two to five days of penicillin therapy. There was a recurrence of the empyemas in 28 per cent of the cases within about sixteen to eighteen days, or about one week after the penicillin was stopped.

Penicillin is also of value in cases of potential contamination of the pleural space following surgical pulmonary resection and traumatic injuries of the lung. The proper evaluation of penicillin in these cases is somewhat difficult, owing to the long recognized tendency toward a spontaneous cure in many instances.

The spontaneous clearing of up to 25 per cent of postpneumonic pleural effusions was noted in surgical textbooks before penicillin or even the sulfonamides were available. This tendency toward a spontaneous cure was especially prevalent in children and was increased by aspirations of the pleural fluid. The tendency toward spontaneous recovery without infection in the majority of cases of hemothorax resulting from stab and gunshot wounds in civilian practice is well recognized. The infections are definitely decreased in these cases by penicillin, sulfonamides, debridement and thoracenteses.

The experiences of chest surgeons over a period of years has shown that the great majority of pneumonectomy patients escape empyemas, despite potential contamination of the pleural cavity occurring as the result of cutting across the infected bronchus. Admittedly a few empyemas do occur in any large series of cases of potential infections of the pleural space, whether due

3. Butler, L. C., B. Perry, K., and Valentine, J. *Bull. M. J.* 2: 171, 1944.

to trauma or to surgery of the lung. The administration of large quantities of penicillin to all these patients during the incipient stages of their infections is to be commended in order to reduce to a minimum the incidence of empyema.

Great care has been exercised in selecting the following 38 cases of empyema reported out of more than 150 carefully recorded cases of penicillin treatment of various types of pulmonary infection. No patients were included who had not received penicillin during the formative stages of the empyema before drainage was required. Several patients who had been discharged from other hospitals as cured by small doses of penicillin were omitted because of the inadequate amount of penicillin administered. All of the many cases in which penicillin and drainage were used simultaneously were omitted. No operative cases were included in which a bronchopleural fistula was suspected

to etiology is as follows: post lobectomy 17, or 48.5 per cent; post pneumonectomy 10, or 28.5 per cent; post pneumonic 8, or 23 per cent. In all but 3 of the lobectomies intrapleural penicillin was given in an average dose of 350,000 units over a period of six days. In all but 1 of the pneumonectomies intrapleural penicillin was administered in the same dosage. In each of the lobectomies and pneumonectomies an average of 1,446,000 units of penicillin was administered over an average period of fifteen days. An average of thirty days occurred between the onset of the disease and the drainage of the empyema. This is a considerably longer time than usually elapses before the drainage of most of our empyemas, especially those following a pulmonary resection, in which the empyema ordinarily develops and requires drainage within less than two weeks after the operation. Drainage was necessitated in a number of these empyemas, especially the postpneumonic ones, by

and drainage of the pleural cavity was maintained for physiologic reasons following the pulmonary resection. These reported cases consist of postpneumonic empyemas and empyemas following lobectomies and pneumonectomies. Penicillin therapy was instituted at the time of operation or several days preoperatively in all of the cases of pulmonary resection.

The accompanying table represents all of the empyemas which developed over a fifteen month period while the patients were receiving penicillin before drainage was instituted. In 2 of the 35 cases reported, 5.4 per cent, recovery occurred without the development of an empyema even after positive pleural fluid cultures were obtained early in the course of the penicillin therapy. Definite empyemas requiring drainage developed while the patient was still receiving penicillin in 17, or 48.5 per cent, of the 35 cases. An average period of eleven days was required after the penicillin was discontinued before the empyemas became established as a clinical entity requiring drainage in the remaining 18, or 51.5 per cent. The distribution of the empyemas in relation

to etiology is as follows: post lobectomy 17, or 48.5 per cent; post pneumonectomy 10, or 28.5 per cent; post pneumonic 8, or 23 per cent. In all but 3 of the lobectomies intrapleural penicillin was given in an average dose of 350,000 units over a period of six days. In all but 1 of the pneumonectomies intrapleural penicillin was administered in the same dosage. In each of the lobectomies and pneumonectomies an average of 1,446,000 units of penicillin was administered over an average period of fifteen days. An average of thirty days occurred between the onset of the disease and the drainage of the empyema. This is a considerably longer time than usually elapses before the drainage of most of our empyemas, especially those following a pulmonary resection, in which the empyema ordinarily develops and requires drainage within less than two weeks after the operation. Drainage was necessitated in a number of these empyemas, especially the postpneumonic ones, by

the patient's continued temperature elevation and the finding of thick pus in the pleural cavity although no organisms could be cultured from the pleural fluid. All of these cultures were incubated for eight days on the advice of Dr. Phillip Varney, who noted small atypical colonies forming in many cultures on about the sixth or seventh day of incubation, after the inhibitory effect of the penicillin had become somewhat dissipated. The colonies would resume their normal growth after several transplants.

The pus was sterile on culture in 8 cases, or 23 per cent, although the persistent symptoms and temperature elevation required drainage.

Staphylococci were predominating organisms, being present in 18, or 51.5 per cent, of the empyemas.

Bacillus pyocyaneus and streptococci both occurred in 5 cases and pneumococci in only 2 cases. In 5 of the 8 postpneumonic empyemas sulfonamides also had been administered in addition to the penicillin, but in none of the pulmonary resections had any of the sulfonamides been given.

COMMENT

The administration of large quantities of penicillin as a prophylactic measure seems advantageous for patients with potential pleural infections whether due to pneumonia or to traumatic or surgical contamination of the pleural space. The period of greatest value in the use of penicillin appears to be during the incipient stages of the infection, preferably even before a pleural effusion has developed. It is also valuable during the developmental stages of a pleural effusion when the fluid remains thin and clear with relatively few pus cells and a sterile culture. The formation of fluid and positive cultures should decrease rapidly within a few days if the penicillin treatment is going to be successful in preventing an empyema. The best results seem to be obtained by a combination of parenteral and intrapleural penicillin, with emphasis placed on the former route. Intrapleural penicillin alone has not proved adequate in our cases. The use of penicillin to avoid drainage of a collection of thick intrapleural pus appears to represent poor judgment and undue optimism. Admittedly, the pus can be rendered permanently sterile in a certain number of cases with tremendous doses of penicillin carried out over a long period of time at great expense to the patient for both penicillin and hospitalization. The most discouraging part of such treatment is the tendency for an unsatisfactory result, even after all of that time, effort and money have been expended.

A trial of two or three weeks with daily penicillin dosages of over 100,000 units plus intrapleural penicillin injections in the presence of a pleural effusion seems sufficient in most of these cases of potential empyema. By the end of this time either the infection should be completely cured or the empyema drained in case signs and symptoms of intrapleural infection persist. Over a week's hospitalization will still be required after the penicillin has been stopped in order to discover a latent empyema whose symptoms have been masked by the penicillin action. A recurrence rate of 28 per cent was noted in the 18 cases reported by Butler, Perry and Valentine. Fifty-three per cent of the cases reported here represent recurrences one or two weeks after the penicillin was stopped.

A certain percentage of patients with potential pleural infection develop empyema, despite large amounts of penicillin administered during the incipient stages of the infection. Some of these patients remain afebrile and asymptomatic, with clear sterile pleural fluid until a little over a week after the penicillin has been stopped. Then suddenly all of the signs and symptoms of an acute empyema develop, which respond readily to the usual surgical drainage. Some other patients, despite the penicillin, develop all the signs and symptoms of an acute or chronic empyema except a positive pleural fluid culture. They may have a continued high or low grade temperature elevation accompanied by weakness, weight loss and the formation of thick turbid pleural fluid containing numerous pus cells. These patients likewise respond to surgical drainage of their "sterile" empyemas.

A third group of sterilized, dry, nontoxic empyema cavities following the administration of large quantities of penicillin over long periods of time represents one of the most difficult problems of all. One has a chronic burned out empyema cavity with thick fibrous walls which prevent the reexpansion or function of the lung, diaphragm or chest wall for the remainder of the patient's life. This clearly simulates the unexpandable lung so familiar to those dealing with tuberculous pleural effusions accompanying artificial pneumothorax. Pileher,

Perry and Wright⁴ and Valentine⁵ all mention the obliteration of the sterilized cavity as one of the greatest problems in the use of penicillin for treatment of empyemas.

The use of a temporary thoracotomy drainage with irrigation of the cavity is mentioned as a possible method of eliminating the pus and fibrin clots. Tillett, Chambier and McCormack¹ report a case of chronic pneumothorax following penicillin therapy, as did Blades, Hamilton and Dugan.³ Keefer and his associates⁶ state in the report of the National Research Council that "when pus in an empyema cavity is sterilized by penicillin it often becomes so thick that a thoracotomy is necessary to furnish adequate drainage."

Kent and Sager⁷ report that chemotherapeutic measures should not delay surgical drainage of empyemas. They also substantiate our experience that catheter drainage is inadequate, as the result of the obstruction of the small tubes by fibrin clots resulting from the use of penicillin. Craig and his associates⁸ at the National Naval Medical Center mention the necessity for surgical drainage to cure finally 3 empyemas after intensive parenteral and intrapleural penicillin therapy.

The surgical findings on thoracotomy in cases of pleural infection treated for several weeks with penicillin would seem to indicate that even sterile, nontoxic empyemas should be treated with surgical drainage, if for only physiologic reasons. The pleural surfaces, especially the parietal pleura, are so much thickened after a few weeks of penicillin "sterilization" that they resemble the walls of a chronic empyema of two or three years' duration. Huge lumps of fibrin fill the cavities and frequently require the enlargement of the thoracotomy openings for their removal with large forceps. A closed intercostal catheter drainage would be entirely inadequate for the cleansing of such empyema cavities. A period of two or three months is frequently required for the lung to reexpand and obliterate the cavity, owing to the rigidity of the walls caused by fibrin deposits. Blades³ reports 2 cases in which reexpansion of the lung was obtained only by surgical decortication of the wall of the cavity in his series of 24 cases treated by penicillin, in which only 3 escaped surgery.

I have found the same extensive fibrin deposits on several occasions in patients with purulent pericarditis who have been treated for two or three months with penicillin. These patients finally required a pericardiotomy for relief of their symptoms of congestive heart failure on a basis of cardiac tamponade or constructive pericarditis. Huge masses of fibrin, which sometimes showed organisms on culture, were found in the pericardial sac.

It does not seem practical to carry on penicillin therapy over a period of two to three months in an effort to cure an established empyema without drainage. Expense to the patient for both penicillin and hospital care is excessive, especially when a thoracotomy will probably be needed eventually to cure the empyema in the majority of the cases and to restore the function of the lung in the remainder. A much wiser course would be to make vigorous attempts to prevent the empyema during the first two to three weeks after the

onset of the infection and then stop the penicillin. In case the empyemas were not completely prevented by that length of time, an eventual drainage would probably be necessary anyway, and the sooner it is done the shorter is the period of drainage required.

My experience with penicillin in over 150 carefully evaluated cases of pulmonary infections of all types including empyemas, lung abscesses and bronchiectasis has shown that penicillin does not alter the surgical principles of treatment in any way. Pus must be drained after it is definitely established, and chronically diseased tissue which is irreversibly damaged and replaced by scar must be excised.

CONCLUSIONS

1. Potential empyemas should be treated with large doses of penicillin during their incipient period of development.

2. Patients who have been "cured" of their empyemas by penicillin should be carefully watched over at least a two weeks period for a possible recurrence.

3. Any toxic or nontoxic turbid pleural effusion containing polymorphonuclear cells following a pyogenic infection treated with penicillin should be surgically drained, even though the pus is sterile on culture.

SKIN DIABETES: HYPERGLYCODERMIA WITHOUT HYPERGLYCEMIA

ERICH URBACH, M.D.
PHILADELPHIA

Dermatologists have long been acquainted with the fact that the institution of a diabetic diet often brings strikingly good results in therapy resistant cases, notably of dermatitis, furunculosis and pruritus, especially in elderly, obese individuals with a purplish red complexion; and that this is true despite the fact that the fasting blood not infrequently reveals normal levels, and the urine is negative as to sugar. Several years ago, in dealing with cases of this kind, on observing a striking rise in the skin sugar levels without a similar increase in the blood sugar, I¹ suggested the term "independent cutaneous glycohistechnia"² to designate the rise in the skin sugar alone. In view of the fact that in these patients diabetic management served to bring the skin sugar levels down to normal and to clear up the skin condition and that a diet rich in carbohydrates brought on a recurrence of the disease manifestations, I assumed that this cutaneous glycohistechnia must be attributable to an underlying diabetes.

Together with Depisch and Sicher,³ and later with Lentz,⁴ I studied the problem of high skin sugar levels in 132 cases. Fasting skin and blood sugar and sugar tolerance tests were made in numerous instances and under a variety of conditions. Just as characteristic blood sugar curves indicate the presence of frank or latent diabetes, we have established the pattern of cutaneous sugar curves which is representative of the metabolic response of the skin in diabetes.

For many years I have been stressing the fact that, for physiologic and pathologic studies of the skin, a far better insight into the metabolism of this organ is afforded by chemical analysis of biopsy specimens than by studies of the blood alone, even with the aid of the sugar tolerance test. The fact that the skin can independently act as a storehouse (for sugar in this instance) is, in itself, no new discovery. For we know very well that there can be urathistechnia, cholesterohistechnia, chlorhistechnia and histohydria without any demonstrable uricemia, cholesterolemia, chloremia and hydremia, necessarily, at the time of the examination. The fact is, of course, that the blood stream merely constitutes the route by which the substances that are to be deposited are conveyed to the storage tissues; occasionally the presence of these substances can be established in the blood, on their way to or from the storage organ; at other times their presence can be demonstrated only in the storage tissues. This lends special physiologic and pathophysiologic significance to the chemistry of the tissues; i. e., to chemical analysis of biopsy skin specimens.

It is obvious that any extensive skin sugar studies must be dependent on the perfection of an extraordinarily accurate microchemical method of examining minute pieces of skin. These requirements have been met, quite satisfactorily, by the introduction of the electric punch biopsy method, which enables us to examine pieces of skin weighing no more than 30 mg. or so; moreover, the wounds occasioned by the excision of these biopsy specimens, with a 3-5 mm. punch, are so small that stitching seems superfluous, and no cosmetic damage is done.

In a recent paper⁴ the microchemical method and the technic employed were discussed in some detail; and some of the more important data on the sugar content of the skin, under physiologic and pathologic conditions, were presented.

The average sugar level of the human skin is 58 mg. per hundred grams; it is rarely higher than 65.5 mg. per hundred grams, and levels approaching 68 mg. per hundred grams are exceptional. Therefore we regard a skin sugar level of more than 68 mg. per hundred grams as pathologic. The average ratio between skin sugar and blood sugar is 61 per cent. It is only when the ratio is 70 per cent or more that we feel justified in speaking of an independent cutaneous glycohistechnia. In table 1, in the column to the left, we presented the levels of 102 patients who served as clinical control cases (contact dermatitis, psoriasis, superficial mycotic dermatitis, skin cancer and so on) and who consistently showed skin sugar levels between 55 and 68 mg. per hundred grams. On the other hand, the 30 cases in the column to the right include 20 patients with skin sugar levels between 68 and 80 mg. per hundred grams and 10 with levels exceeding 80 mg. per hundred grams. However, only 16 of these 30 cases may be properly included in the "independent cutaneous glycohistechnia" group, since these are the only cases showing a skin sugar to blood sugar ratio of more than 70 per cent (table 2).

These figures must inevitably lead to the conclusion, first of all, that a patient with a normal fasting blood sugar level can at the same time show more or less of an elevation of his fasting skin sugar level. Quite a number of these patients presented clinical skin manifestations which were completely therapy resistant until a diabetic diet low in carbohydrates was instituted, usually reinforced by a brief course of insulin treatment. The clinical improvement was regularly accompanied

by a return to normal skin sugar levels, which, however, again rose to pathologic levels when resumption of an ordinary diet containing average amounts of carbohydrate brought on a recurrence of the clinical symptoms, such as furunculosis, eczema and pruritus. A few examples may serve to illustrate these statements:

CASE 1.—A woman aged 52 suffered from an extensive subacute dermatitis of the body, which failed to yield to many weeks of painstaking treatment in a hospital. The blood sugar toler-

55-68	102	0
68-80	...	20
Over 80	...	10

ance test was completely normal, as is shown in chart 1. The skin sugar tolerance test began with a slightly increased fasting level (68 mg. per hundred cubic centimeters), reached a peak (128 mg. per hundred cubic centimeters) after one hour, was still quite high (108 mg. per hundred cubic centimeters) after three hours, when the blood had begun to show hypoglycemic levels, and had not returned to its initial level by the end of the fourth hour. Institution of a low carbohydrate diet, together with small doses of insulin, brought about speedy improvement of the eczema. In conformity with the clinical improvement, the fasting skin sugar level was normal (59 mg. per hundred grams) after a week, while the blood sugar level was virtually unchanged (100 mg. per hundred cubic centimeters). Furthermore, the clinical improvement was paralleled by the response of the skin to the sugar tolerance test, during which the skin sugar now dropped to a point below its initial level by the end of the third hour (chart 2). Strict observance of the low carbohydrate diet alone caused the skin manifestations to disappear completely; however, they recurred when the diet was not strictly adhered to. This case is noteworthy because of the fact that exacerbations of the dermatitic manifestations could invariably be cleared up by means of dietary adjustments and insulin and without any kind of local treatment.

CASE 2.—A man aged 49 had been suffering for five years from severe, constantly recurrent furunculosis. During this period he had been obliged to seek hospital treatment ten times (in three different hospitals). In view of the fact that the

patient was very obese and that his complexion was purplish red, blood sugar tolerance tests were repeatedly made; but, since these were consistently normal, it seemed impossible to make a diagnosis of diabetes. When we performed the sugar tolerance test, we also found a nearly normal curve (97, 164, 164, 139, 97 mg. per hundred cubic centimeters); an examination of the skin sugar, on the other hand, revealed the high fasting level of 81 mg. per hundred grams. We refrained from performing a complete skin sugar tolerance test in this case because of the danger of infection presented by the severe furunculosis. The patient was put on a strict diabetic diet and given 10 units of insulin three times daily. By the end of the eighth day the furuncles had vanished completely, without any

kind of local therapy. Thereupon, by way of an experiment, the patient was put on a diet free from salt but including average amounts of carbohydrates; this had to be stopped after the third day, however, because of the reappearance of furuncles. Strict adherence to a diabetic diet plus 30 units of insulin daily again served to clear up the condition, and the patient suffered no further attacks during the subsequent seven days, when he was on a very low carbohydrate diet. Then he was again put on a salt free diet of ordinary carbohydrate content, and again this had to be stopped after four days because of the reappearance of furuncles. Subsequently, throughout the months that the patient was kept under observation, a very low carbohydrate diet kept him free from all clinical manifestations without the use of insulin.

CASE 3.—A man aged 58 gave no family history of diabetes. He had been suffering from severe, recurrent furunculosis with high fever for eight years. A sugar tolerance test performed during this period had shown a normal fasting level but a blood sugar curve somewhat suggestive of the diabetic type. Subsequent institution of a suitable diet, together with insulin treatment, had brought speedy clinical improvement. During the next eighteen months the patient had lived on a diet low in carbohydrates. Then he attempted to return to a normal diet, since the sugar tolerance test with 100 Gm. of dextrose had shown a perfectly normal blood sugar curve (101, 158, 134, 98, 103 mg. per hundred cubic centimeters) and a skin sugar level of 68 mg. per hundred grams. However, a fortnight later furuncles again made their appearance, while the skin sugar

Chart 1.—Independent cutaneous glycohistechia: note normal blood sugar curve (solid line) but pathologic skin sugar curve (broken line).

Chart 2.—Influence of low carbohydrate diet on skin sugar curve in a case of independent cutaneous glycohistechia.

level rose to 84 mg. per hundred grams, although the fasting blood sugar level (104 mg. per hundred cubic centimeters) was normal. On a diabetic diet the skin manifestations once more showed speedy improvement, while the skin sugar level dropped to 72 mg. per hundred grams and the blood sugar level of 101 mg. per hundred cubic centimeters remained virtually unchanged. During the many months this patient was kept under observation he too remained completely free from all clinical manifestations on a low carbohydrate diet alone.

The triad of (1) a high skin sugar level, (2) a strikingly good and long lasting tolerance of relatively large quantities of insulin in association with low carbohydrate diet and (3) the clinically beneficial effect of the latter on furunculosis (or, conversely, the recurrence of abscess formation on a high carbohydrate diet) would certainly seem to point to an underlying diabetes in these 2 cases of chronic furunculosis.

CASE 4.—A man aged 74 presented the typical picture of diabetic balanitis. This diagnosis was rejected, however, because the blood sugar tolerance curve was perfectly normal; investigation of the skin sugar, on the other hand, disclosed the presence of an independent cutaneous glycohistechia (the fasting skin sugar level was 80 mg. per hundred grams). A diabetic diet plus insulin promptly brought favorable results.

The other cases of this kind which we have had occasion to observe responded in a similar manner.

From our observations we must conclude, therefore, that among the cases of so-called "independent cutaneous

glycolistechia" and notably, but not exclusively, among those showing skin sugar levels of more than 80 mg. per hundred grams there are some patients in whom the independent skin sugar rise is in direct causal relationship with the presenting skin disease. This view is supported by the fact that diabetic management serves both to clear up the dermatosis and to lower the skin sugar level, and by the fact that administration of carbohydrates is followed by a rise in the skin sugar.

We have suggested the term "skin diabetes" to designate the syndrome of therapy resistant, recurrent or chronic dermatosis, a high fasting skin sugar level together with a normal blood sugar curve, and pronounced improvement of the skin disease, as well as a drop in the high skin sugar level, on a low carbohydrate diet, sometimes combined with insulin. The pros and cons of this new term will be discussed further on.

CONCERNING THE PROBLEM OF "SKIN DIABETES"

It is a difficult matter, unquestionably, to evaluate the true significance of a case presenting an independent rise in the skin sugar level and a perfectly normal blood sugar curve. Does this picture represent a preliminary phase of diabetes or is the syndrome just described in no way related to diabetes? What is the evidence for or against a connection with diabetes?

The possibility of a genuine pancreatic diabetes would seem to be excluded by the virtually normal behavior of the blood sugar tolerance curve and by the fact that it has not been possible as yet to demonstrate that a case of this kind has progressed to a frank diabetes. This might be explained partially by the fact that, since pronounced cases of this kind cannot tolerate an average, normal, sugar containing diet, skin manifestations soon develop, which, in turn, call for the elimination of carbohydrates or at least a sharp reduction in their consumption. The possibility of a diabetic etiology might also be negated by the fact that mild cases of true diabetes without skin lesions present normal skin sugar levels together with a moderate fasting hyperglycemia, while we have mostly found a considerable rise in the skin sugar in diabetic individuals with skin manifestations.⁴ I must hasten to point out, however, that the fasting skin sugar level may be assessed as truly normal only when there is nothing pathologic about the skin sugar tolerance curve. (See skin sugar curve 1, which shows a high normal fasting skin sugar level but a diabetes-like skin sugar tolerance curve.)

These various facts would seem to suggest that the disturbance in the skin's carbohydrate metabolism, in cases presenting independent cutaneous glycolistechia, should be regarded as an entity in no way related to the general sugar metabolism of the body and thus, of course, unrelated to ordinary diabetes mellitus.

On the other hand, I should like to mention the following points, which would seem to indicate a direct connection between the clinical syndrome described and a disturbance in the carbohydrate metabolism, as in diabetes mellitus: (1) the high fasting skin sugar levels, which not uncommonly attain and even exceed levels of 80 mg. per hundred grams; (2) the pathologic course of the skin sugar curve, following oral administration of quantities of dextrose—a curve which is characteristically diabetic, both in its rise and in its subsequent course; (3) the return to normal of the fasting skin sugar level, as well as of the entire course of the curve, following institution of a low carbohydrate diet, notably in combination with insulin.

In support of the assumption that the skin sugar is virtually dependent on the pancreas, I should like to recall the conditions in totally pancreatectomized dogs. As mentioned elsewhere,³ the sugar meal causes the skin sugar level to rise to heights never attained by the blood sugar. This can be explained only by the fact that the normal intermediary metabolism of sugar in the skin is dependent on the presence of insulin and that there is a vast concentration of sugar in the skin tissue when there is a lack of insulin.

This interpretation leads to the conclusion that, in cases presenting independent cutaneous glycolistechia and apparently normal blood sugar regulation, there is a disturbance of the carbohydrate metabolism in the skin, a disturbance which may, in my opinion, be related in some manner to a partial interference with the action of insulin involving only the tissues of the skin. This pattern of behavior may be succinctly described by the term "skin diabetes."

The view that the sugar in the skin is not brought there only by way of passive diffusion from the blood, but that there is also an independent, intermediary carbohydrate metabolism in the skin as an organ, has had recent further corroboration by additional, important evidence.⁴

SUMMARY

The term "skin diabetes" is suggested to serve as a designation for the syndrome of therapy resistant skin disease (generally presenting the clinical picture of furunculosis, sweat gland abscesses, eczema, pruritus), high fasting skin sugar level together with a normal blood sugar curve, and pronounced improvement of the dermatosis, as well as fall in the high skin sugar level on a low carbohydrate diet, sometimes combined with insulin.

The following points of evidence lend support to the view that there is a connection between the clinical syndrome and a disturbance in the carbohydrate metabolism, as in diabetes: (1) the high fasting skin sugar levels, which attain and even exceed 80 mg. per hundred grams; (2) the pathologic and characteristically diabetic course of the skin sugar curve following oral sugar forcing; (3) the return to normal of the fasting skin sugar level, as well as of the skin sugar tolerance curve after a low carbohydrate diet, notably in combination with insulin.

The evidence tending to negate any connection with a true pancreatic diabetes has been given due consideration.

However, quite aside from the question as to whether or not cases presenting independent cutaneous glycolistechia are actually to be regarded as cases of "skin diabetes," it may be safely said, on the basis of clinical experience, that a diabetic diet should unhesitatingly be tried in cases of therapy resistant skin diseases such as furunculosis, eczema or pruritus, even when the blood sugar tolerance test is normal.

422 Medical Arts Building.

Psittacosis (Ornithosis) of Nonpsittacine Birds.—Pigeons are known to be extensively infected with a psittacosis-like virus in America, England and Australia. Undoubted cases of the human disease have been contracted from pigeons, but the virus strains differ recognizably from parrot strains, and there is a general tendency to adopt Meyer's name, ornithosis, for the types of virus derived from nonpsittacine birds. Again there is no reason to believe that the natural history of the infection differs in any essential respects from that of psittacosis.—Burnet, Frank MacFarlane: *Virus as Organism*, Cambridge, Mass., Harvard University Press, 1945.

Clinical Notes, Suggestions and New Instruments

INTRAVENOUS NUTRITION FOR EIGHT WEEKS; PARTIAL ENTERECTOMY, RECOVERY

ALEXANDER BRUNSCHWIG, M.D., ROBERT R. BIGELOW, M.D.
AND SABRA NICHOLS, S.B., CHICAGO

The use of casein digests for intravenous nutrition has received some recognition. Such nutritional support for relatively brief periods often conveys the impression of affording salutary effects, but these impressions are essentially uncontrolled observations. Our purpose in this communication is to record an instance of intravenous nutrition carried out for forty-six days, the patient receiving no food by mouth and at the end of this period being subjected to a major abdominal operation (partial enterectomy), with recovery and continued intravenous nutrition for nine more days. The total period of nutritional support entirely by vein was fifty-five days before food was permitted by mouth.

REPORT OF CASE

C. E., a man aged 50, admitted Feb. 2, 1945, presented hypertension of 204/130 and a palpable mass in the right side of the abdomen. Retrograde pyelograms were negative. Urea clearance was 21 (normal 40-65). With the diagnosis of retroperitoneal cyst or solid tumor, laparotomy was performed February 12. The abdomen was entered through a right rectus incision, and the mass was found to be a cyst 10 cm. in diameter, bulging forward from the lower anterior pole of the right kidney. The lateral reflection of peritoneum from the mesentery of the ascending colon was incised and the cyst dissected free with a narrow margin of kidney parenchyma and removed without rupture. Hemorrhage was arrested from the kidney, and the abdomen was closed with two soft rubber drains to the excision site. During the second and third days after operation the urine output was 200 and 325 cc. respectively; thereafter it exceeded a liter daily. On the second day the blood nonprotein nitrogen rose to 132 mg. per hundred cubic centimeters. During the first eight days after operation the patient hiccuped severely and frequently (uremia?), coughed considerably, had little appetite and exhibited a blood nonprotein nitrogen count of 73 to 136 mg. per hundred cubic centimeters, with a trace to 2 plus of albumin in the urine (preoperative nonprotein nitrogen 38 mg. per hundred cubic centimeters).

The wound appeared healed on the fourteenth day and all the sutures were removed. On the sixteenth day (February 27) there was almost complete disruption following cough, and at repair a loop of small bowel was observed to have become healed into the depths of the wound over a distance of about 10 cm.; there were two oval patches of apparent necrosis each about 3 cm. in diameter on the bowel wall. By the end of four days small bowel contents poured out of the wound in copious quantities. The quality of this discharge clearly revealed that the fistulas were high in the small bowel. As time went on the wound again separated widely and its floor was composed of a flat patch of jejunal mucosa measuring 8 by 4 cm., with afferent bowel opening in the lower angle and efferent opening in the upper angle (A in the illustration). When several attempts to ingest food were made, a copious discharge from the wound occurred in a short time; this consisted of the partially digested nutriment. To conserve bile and intestinal juices a large rubber T tube was constructed to bridge the gap, and this functioned successfully but did not prevent some escape of bowel contents through the wound. Digestion of the abdominal wall was prevented by constant application of aluminum paste. Ingestion of food, tried once with the T tube in the bowel defect, was not successful, as the tube, plugged by the ingested food, became extruded from the wound.

The patient had been nourished entirely by the intravenous route since February 27. He was requested not to take any-

thing by mouth to reduce the quantity of material passing down the bowel. He did, however, drink a glass of water from time to time but did not ingest food. The latter fact was confirmed by the quality of discharge on the dressings. During the period of intravenous nutrition an electric suction pump connected to a rubber tube in the wound was operated at frequent intervals by the patient. This aided materially in reducing the "spillage" about the wound.

The standard intravenous injections received daily from February 27 to April 22 (fifty-five days) were as follows (no food being ingested by mouth): 1,500 cc. of 10 per cent dextrose in saline solution (600 calories, 13.5 Gm. of sodium chloride) and 1,000 cc. of 5 per cent Amigen (enzymic digest of casein) in 5 per cent dextrose (380 calories), a total of 980 calories and 13.5 Gm. of sodium chloride.

He also received vitamins C, B and K hypodermically at intervals. There were days in which the injections were varied; for example, 800 cc. of 8 per cent gelatin solution in saline solution was substituted for 1,000 cc. of dextrose and casein digest on three occasions, and for five days on another occasion. On one day gelatin was injected in addition to Amigen and dextrose. During a few days the total amount of dextrose injected was 275 Gm. On several days no Amigen or gelatin was received.

TABLE 1.—Blood Transfusions

TABLE 2.—Nitrogen Balance

Number of Days	Average Daily Nitrogen Intra-venously as Amigen, Gm.	Average Daily Glucose Intra-venously, Gm.	Average Daily Total Nitrogen in Urine, Gm.	Average daily Nitrogen Balance, Gm.
5	6.00	300	6.78	-0.78

Blood transfusions were also given on five occasions. The dates are given in table 1.

Nitrogen balance studies were not conducted throughout the whole period, but during a period of five days data were obtained as summarized in table 2.

For obvious reasons the nitrogen balance during the whole period of intravenous nutrition cannot be stated to have been -0.78 Gm. daily but it probably did not vary a great deal from this. For purposes of discussion, if this figure is adopted, the total loss of nitrogen for the fifty-five day period of intravenous nutrition would be 43 Gm. This depletion is not excessive, and in a study of nitrogen loss postoperatively in routine patients during the first ten days a number were found to have had greater nitrogen losses during such periods.

By April 12 (after forty-six days of intravenous nutrition only) the skin edges of the separated wound had healed to the margins of the flattened patch of jejunal mucosa in the bottom of the wound. The patient was then subjected to laparotomy for closure of the wound and reestablishment of intestinal continuity. The abdomen was entered through a horizontal incision extending mesially from the opened wound, and loops of small bowel were separated from one another by transection of fibrous adhesions. The opened segment of upper jejunum was freed from the old wound. This segment, measuring 8 cm. in length, was excised together with a triangular portion of mesentery. The transected ends of the

This study was conducted with the aid of the Charles and Mary F. S. Worcester Fund of the University of Chicago.

bowel were invaginated, and continuity of the alimentary tract was reestablished by side to side anastomosis (*B* in the illustration). The abdominal wounds were closed in layers with soft rubber drains to the right peritoneal gutter. Intravenous nutrition was maintained for nine more days and the patient was then permitted to ingest food by mouth, which he did readily and without distress. The wounds remained closed, but secondary infection developed in the depths, owing to the fact that the operation had been performed in a contaminated field. The patient was discharged May 12, 1945; on admission he weighed 72.2 Kg. and at the time of discharge 59.7 Kg. He was seen in the outpatient clinic on May 25; the wounds were healed, he was consuming a normal diet and he had no complaints.

COMMENT

As already stated, the clinical impressions of the beneficial effects of intravenous nutritional support by nitrogenous nutrients, dextrose and so on are uncontrolled observations when the period of study is relatively brief. The regimen employed for this patient was not ideal and was deficient in several respects, but the data obtained suggest that in this case pronounced depletion of protein was obviated.

During the entire period of intravenous nutrition the patient's condition was fair to good, and after forty-six days his condition was such as to raise little question as to his ability to tolerate laparotomy with enterectomy and jejunal anastomosis. To insure maximal rest of the alimentary canal, food

After forty-six days laparotomy for partial enterectomy and enteroenterostomy were performed, closing the fistula. Recovery was uneventful, intravenous nutrition being continued for nine days after operation. The experience in this case suggests that intravenous nutrition permitting the withholding of food by mouth might prove beneficial in the management of large fistulas high in the small bowel, since discharges from the fistulas would be appreciably reduced and thus permit a degree of healing which might then be completed by surgical closure.

950 East Fifty-Ninth Street.

BENZIDINE AS CAUSE OF OCCUPATIONAL DERMATITIS IN A PHYSICIAN

RUDOLF L. BAER, M.D., NEW YORK

Eczematous dermatitis is not an uncommon occupational disease among physicians and dentists. Often merely a constant annoyance or handicap, the dermatitis may be so severe, intractable and incapacitating that it forces the physician to change his specialty or even to give up his profession entirely.

Often, particularly in surgeons, the dermatitis is due largely to the primary irritant effects of chemical agents such as soap or alcohol and physical agents such as friction (scrubbing), heat and maceration (under rubber gloves). In other cases the dermatitis is due mainly to allergens to which the physician is exposed in the course of his work. Notorious among these allergens are rubber gloves, local anesthetics and some local antiseptics.

This case of occupational allergic eczematous dermatitis is reported because the causal allergen, although used by many thousand doctors in their everyday work, has to my knowledge never been described as a cause of occupational dermatitis in physicians.

REPORT OF CASE

Dr. S. G., aged 32, first seen in the practice of Dr. M. B. Sulzberger and myself on Jan. 23, 1945, complained of a recurring eruption on the hands and face from which he had suffered on and off since September 1944. In the recurrent attacks the left hand was more severely involved and was at times the site of secondary pyogenic infection associated with lymphadenitis and elevation of temperature up to 103 F. Soothing local treatment and sulfadiazine taken by mouth usually controlled the eruption, and the superimposed infection within two to three weeks.

A recurrence which began Jan. 1, 1945 resembled the previous ones except that the anterior part of the face was more seriously involved with erythema and itching. On January 23, when the patient was first seen, this attack had largely subsided. He still presented slight erythema and scaling of the palms and fingers, with drying vesicular lesions at the edges of the affected areas. There were no signs of a fungous infection of the feet. No fungi could be found on microscopic examination or in cultures of scrapings from the lesions on the hands. The remnants of the eruption cleared up rapidly under bland local treatment.

A presumptive diagnosis was made of allergic eczematous contact-type dermatitis with secondary pyogenic infection. Patch tests were carried out with the following suspected materials (each in the correct test concentration¹): two types of hair tonics, scented talc, toothpowder, two types of nose drops, solution of formaldehyde, zephiran chloride (alcoholic solution), zephiran chloride (aqueous solution), metaphen, merthiolate (alcoholic solution), merthiolate (aqueous solution), rubbing alcohol, a proprietary ointment containing histamine, electrode jelly, lubricating jelly, two types of endocrine substances in oil, bismuth in oil, neoarsphenamine, x-ray fixing solution, x-ray developing solution, rubber finger cot and rubber gloves. None of these materials elicited a significant reaction. In view of the fact that the causal agent had not been found and in order to increase the chances of obtaining an accurate history of suggestive exposures, the patient was asked to return immediately in case of signs or symptoms of a recurrence.

On February 2 the patient returned and stated that two days previously at about 6 p. m. he had noticed itching of the finger-

Diagram showing: *A*, large opening in upper jejunum (jejunal fistula, *f*) and opened segment of bowel (*a*) efferent opening, (*b*) efferent opening. Until skin edges of wound healed to bowel mucosa the patient received all nutriment by vein and no food by mouth over a period of forty-six days; *B*, repair of jejunal fistula by excision of opened segment and side to side anastomosis (*ee*). After operation the patient received intravenous nutriment for nine days and no food by mouth.

by mouth was withheld for nine days after operation while intravenous nutrition was continued. Judging from general experience the patient would not have been expected to have remained in as good condition as he did and to undergo successfully the surgical procedures described had there been no benefits from intravenous nutrition. The management of large fistulas high in the small bowel is complicated by the copious discharges, which often result in varying degrees of digestion of the wound edges. Furthermore, general nutritional deterioration may result because of the loss of electrolytes, and fluid from the fistulas as well as escape of appreciable quantities of partially digested food. The vicious circle develops, as increased ingestion of food increases the discharges from the fistula. The experiences in the case reported suggest that large fistulas high in the small bowel may be treated by withholding all nutriment by mouth for a period during which nutrition is afforded by the intravenous route. The discharges from the fistulas are reduced to a minimum, and frequent suction of the wound facilitates healing. When the latter has become maximal, operative closure is carried out and its success is aided by maintaining the bowel at rest.

SUMMARY

A patient with a large upper jejunal fistula received intravenous casein digest, dextrose and saline solution intravenously for a period of eight weeks. No food was ingested by mouth.

1. Sulzberger, M. B., and Baer, R. L.: *Year Book of Dermatology and Syphilology*, Chicago, Year Book Publishers, Inc., 1943, pp. 25-42.

of the left hand. The next morning there had been a recurrence of the characteristic eruption. Examination showed pronounced edema of the left hand with erythema and vesication, particularly of the fingers. The right hand showed the same changes in a less pronounced form. Questioning brought to light the following additional materials to which the patient had been exposed during the twenty-four hour period preceding the onset of the most recent attack: sodium morrhuate in benzyl alcohol, acetic acid, testosterone propionate in oil, vitamin B complex solution, thiamine hydrochloride solution, Benedict's solution, benzidine powder and a proprietary lousicide. Patch tests with these materials in the correct test concentrations were applied. Benzidine powder produced a very strong eczematous reaction, while none of the other materials elicited a significant response. A recheck of the patient's activities revealed that at each occasion he had performed a benzidine test for blood in a stool specimen just preceding the various recurrences of his hand eruptions.

COMMENT

The present case is interesting because the allergen involved seems to be an unusual cause of occupational dermatitis among physicians. No reference could be found in the literature to any case in which benzidine had been the cause of an occupational dermatitis in a physician. However, Schwartz and Tulipan² listed benzidine among the dye intermediates causing dermatitis in workers engaged in the manufacture of dyes.

SUMMARY

A physician suffered from a severe recurrent eczematous dermatitis of the hands and a milder dermatitis on the face. Patch tests with a series of materials to which he had been exposed in the course of his work showed that he was strongly hypersensitive to benzidine powder. A recheck of the dates of the various attacks of dermatitis revealed that each attack had started on a day when the patient had performed a benzidine test for blood in a stool specimen.

962 Park Avenue.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following report. HOWARD A. CARTER, Secretary.

FIVE YEAR SURVEY OF METHODS FOR ARTIFICIAL RESPIRATION

BERNARD D. ROSS, M.D., Ph.D.
MIAMI, FLA.

Artificial respiration is a form of therapy which does not readily lend itself to clinical study. Acute asphyxia requires immediate treatment if the patient is to recover, and seconds may mean the difference between recovery and death. As a result, laymen cannot wait for the arrival of a physician before instituting treatment, and rarely does a physician arrive before the critical period of treatment is over. Artificial respiration has thus been necessarily entrusted to the hands of nonmedical groups and individuals such as firemen, policemen and lifeguards. The physician does not usually think in terms of going to the public to get data on therapy, but it appears necessary in the case of artificial respiration, for it is laymen who administer the treatment and observe the results in the overwhelming majority of cases.

Experimental work has been done in this field, but the results are not generally accepted as being conclusive. Measurements have been made of the respiratory exchange in normal human subjects with the use of

various methods of artificial respiration,¹ but there have been few such reports, and different observers have not agreed in their findings. Furthermore, there is good reason to doubt that values for the respiratory exchange in normal subjects have any bearing on the exchange in the deeply asphyxiated and apneic individual whose muscles are atonic and without resilience. This is especially true of the Schafer prone pressure method, which depends on elastic recoil of the diaphragm for production of inspiration. The newly developed rocking method of Killick and Eve² is unique in that it does not depend on elastic recoil. In this method the patient is alternately tipped back and forth on a stretcher, the weight of the viscera causing the diaphragm to move back and forth as a piston. This method is under trial in England but has not been used to any extent in this country.

Animal experimentation has shown the importance of the use of oxygen and carbon dioxide in the treatment of acute asphyxia. Loughheed, Janes and Hall³ have demonstrated that the carbon dioxide as well as oxygen content of the blood diminishes as asphyxia progresses. Since carbon dioxide is a normal stimulant of the respiratory center, its use in conjunction with oxygen in the treatment of acute asphyxia appears quite rational. There are some who advocate the inhalation of these gases simultaneously with the application of a manual method of artificial respiration,⁴ and there are others who have demonstrated the value of administering these gases by alternate pressure and suction.⁵ There are some who contend that the use of alternating pressure and suction is unphysiologic⁶ and that pressure great enough to inflate the lungs will cause tissue injury. The work of Coryllos⁷ shows, however, that in the dog a pressure far above that needed for respiratory exchange must be attained before evidence of injury appears.

For fourteen years the Council on Physical Medicine has been investigating methods, both manual and mechanical, recommended for the administration of artificial respiration. During this time the Council has investigated many devices and has published reports on them. Realizing that data obtained from experiments on dogs and normal human beings did not give sufficiently satisfactory evidence for the evaluation of different methods of resuscitation, the Council decided to conduct a survey of results obtained "under clinical conditions." The aim of the survey was to get sufficient data from various life-saving organizations on actual cases of artificial respiration to permit the drawing of conclusions regarding the relative efficacy of different methods. A progress report was published in 1943;⁸ the present paper is a final report of the five year study.

A number of organizations were invited to cooperate with the Council, as for example fire departments, life saving crews at beaches and large commercial organi-

zations, e. g. electric, steel and chemical manufacturers. Some of the commercial organizations were not interested and did not care to cooperate, while others were anxious to assist in the work but were unable to follow through because of an insufficient number of cases. Reports were received from the U. S. Coast Guard and the Chicago, Detroit and Los Angeles fire departments. These organizations provided a sufficient number of cases to make the investigation worth while, whereas manufacturers and other institutions that sent too few reports were dropped. It was felt that their reports would not contribute to a statistical evaluation.

The aforementioned organizations were selected because each had a trained life-saving crew which stood ready to render service at a moment's notice and was equipped to make a fairly accurate report and to keep records. The cooperating groups were requested to report every case, whether revival or death occurred. They were asked to state the cause of asphyxia, the method of resuscitation, the time that elapsed before artificial respiration was begun and an estimate of the results. Autopsy reports were also requested.

The Council adopted a case report blank, and it was used by the Chicago Fire Department. The U. S.

Coast Guard and the Los Angeles Fire Department employed their own blanks. The Detroit Fire Department used its own forms, which had previously been revised at the suggestion of the Council.

Material presented in this paper represents reports of cases of asphyxia occurring from 1940 through 1944. Table 1 shows the number of reports contributed by each cooperating group. They are classified according to the type of asphyxia and the results obtained. The cases were first separated into two major groups, those with complete cessation of respiration and those with abnormal respiration. All cases in which there was any type of spontaneous respiratory movement were included in the latter group. Cases were further classified into cardiac and noncardiac groups.

The Chicago Fire Department contributed the most reports, 1,735. The Los Angeles Fire Department contributed 1,259, the Detroit Fire Department 192, the U. S. Coast Guard 156 and other sources 10, for a total of 3,352. There were 1,633 cases in which there was no spontaneous respiration at the start of treatment. Of these there were 227 survivals and 1,406 deaths. Cardiac cases comprised 8 per cent of the survivals and 55 per cent of the deaths. There were 1,719 cases of abnormal respiration, in which there were 1,679 survivals and 40 deaths. In this group cardiac cases comprised 39 per cent of the survivals and 78 per cent of the deaths.

CASE REPORT OF ASPHYXIA FOR THE COUNCIL ON PHYSICAL MEDICINE OF THE AMERICAN MEDICAL ASSOCIATION

- Name of Patient: Address: Site of Accident: Date of Accident: Time Artificial Respiration First Started: Age: Sex: Occupation: Time Discovered:
- Cause of Asphyxia: Carbon Monoxide Asphyxia of the Newborn Drowning Heart (Specific Diagnosis) Suffocation Other Causes
- Had Breathing Completely Ceased When Patient Was First Discovered?
- Was Artificial Respiration Administered Before Life Saving Crew Arrived? By Whom? What Method Was Used? How Long?
- Condition of Patient at Start of Artificial Respiration: Was Heart Beating? Was Patient Breathing? Could Pulse be Felt? Was Respiration Normal? Color of Skin (Pink? Blue? White?)
- Method of Artificial Respiration Used by Life Saving Crew: A. Manual Schafer Prone Pressure How Long? Other Manual Method How Long? B. Mechanical: Resuscitator² (see definition below) How Long? Inhalators³ (see definition below) How Long? Other Mechanical Device How Long? Make and Manufacturer C. Combination of Manual and Mechanical (if combination was used, please fill in A and B also): Was Manual Method Used Before or After Resuscitator? Was Manual Method Used Directly Before or at the Same Time as Inhalator?
- If Two or More Methods Were Used in Succession Was the Patient Breathing Before the Second (and/or Third? Etc.) Method Was Used?
- Was Patient Alive at End of Artificial Respiration? Pulse After Revival Respiration Any Bleeding from Nose or Mouth? Remarks on General Condition of Patient
- Was a Physician Present? Name: Address: Phone No.: How Long After Discovery of Asphyxia Did Physician Arrive?
- Who Administered Artificial Respiration? (Name and Address) Physician: Lifeguard: Fireman: Coast Guardsman: Others: If Not a Physician, What Type of Training Did He Have?
- Was Patient Hospitalized After Resuscitation? Name of Hospital: Address:
- Was Person in Average Health Prior to Accident?⁴ Heart Disease (Specific Diagnosis)? Tuberculosis? Diabetes? Other Disease?
- Subsequent History of Recovered Patient⁴ Pneumonia? Other Remarks:
- Was an Autopsy Performed? By Whom? Was There Any Evidence of Pathologic Condition of Lungs? Other Findings:

Signature of Physician: Date:
Signature of Person Administering Artificial Respiration: Date:

- This information is for a statistical study of methods of artificial respiration. If unable to fill in all items, please give as much information as possible.
- Resuscitator: Any device for blowing and sucking air or some other gas mixture in and out of the lungs.
- Inhalator: Any device supplying oxygen and carbon dioxide for the patient to breathe without mechanically blowing and sucking.
- Information about history of patient to be obtained from family physician or relative.
- If insufficient space is allotted, record additional information on separate paper. Write a short history regarding accident on a separate sheet.

RESUSCITATION OF THE APPARENTLY DROWNED

U. S. COAST GUARD BLANK

- Coast Guard Unit: Place: Date of Accident
- Name, age and sex of person imperiled:
 - P. O. address:
 - Exact time of accident:
 - Distance and direction from unit:
 - Was scene of accident visible from unit?
 - Cause of accident:
 - Temperature of water and atmosphere:
 - Length of time under water:
 - How was time under water determined?
 - By whom taken from water?
 - Did patient rise to the surface after first disappearing? If so, how many times?
 - Did patient breathe or show any other signs of life when taken from the water?
 - How soon after accident did members of Coast Guard arrive on scene?

- 14 Were efforts made to revive person before the Coast Guard took charge? If so, state by whom, how long and the means employed
- 15 Was the patient apparently dead when taken in charge by members of the Coast Guard?
- 16 Were patient's jaws clenched?
- 17 How soon after artificial respiration was begun did patient show signs of life?
- 18 What were the first signs of life shown?
- 19 What signs of life, if any, were shown while water was first being expelled from the lungs?
- 20 State probable quantity of water expelled or drained through the mouth on turning patient on stomach the first time and second time, respectively
- 21 Length of time artificial respiration was employed
- 22 How many Coast Guard men took part in this resuscitation?
- 23 What means were employed during process of artificial respiration to impart warmth to the extremities?
- 24 What other means were employed to restore circulation?
- 25 What stimulants, if any, were administered?
- 26 Give method of resuscitation employed
- 27 Was patient resuscitated?
- 28 State name and address of physician called, time of arrival and service rendered

Remarks

U S C G
Commanding Officer

INSTRUCTIONS

1 This form shall be submitted by all units on each occasion of resuscitation of the apparently drowned, whether or not resuscitation is successful. It shall be prepared in quadruplicate. The original and one copy shall be forwarded to headquarters via the district commander and a copy shall be included for his files, a copy shall be retained in the files of the unit concerned.

2 Under "Remarks" relate in detail the circumstances of the accident, describe each step taken in restoring the patient, and state the successive signs of returning life shown while resuscitation was being performed. If the attempt to revive the patient was unsuccessful, obtain the opinion if available, of physician or local health officials as to whether or not patient was dead on removal from the water and if death was due to causes other than drowning. State cause of death, if known.

3 If necessary, use separate sheets of paper, 8 by 10½ inches in size, for the submission of additional remarks or in answer to any of the questions on page 1 of the form.

Table 2 represents an analysis of the 227 cases of nonbreathing in which survival occurred. The common causes of asphyxia in this group, in order of frequency, can be seen to be asphyxia neonatorum, immersion, heart disease, carbon monoxide poisoning, acute respiratory infections, poisoning with depressant drugs, suffocation, convulsions, asthma and stroke. In the miscellaneous group are causes which occurred fewer than four times each and it includes tracheal obstruction, epilepsy, acute alcoholism and anesthesia. There were 153 cases in which a resuscitator was used successfully. In 13 of these the Schafer method was used beforehand. There were 58 cases in which the Schafer method caused resuscitation. In 8 of these an inhalator was used at the same time as the Schafer method. The other less commonly used methods follow in the table.

Cases of impaired respiration in which survival occurred are presented in table 3. Cardiac cases form the largest group, 653, with other causes in order of frequency being carbon monoxide poisoning 252, asphyxia neonatorum 162 and asthma 98. The other less common causes follow in the table. Among the miscellaneous causes were hysteria, diabetes, hemorrhage, acute indigestion, acute alcoholism, leukemia, carcinoma, exhaustion, heat exhaustion, insulin shock, perforated peptic ulcer, food poisoning, and poisoning with sulfur dioxide, with ammonia and with methane. The inhalator was the method used in the great majority (95.2 per cent) of the 1,679 cases.

Table 4 represents the cases in which death occurred. It is probable that many of the patients in this group were already dead at the time treatment was started, but cases were not excluded unless (1) there was definite evidence that thirty minutes or more had elapsed between cessation of respiration and start of treatment, (2) there was evidence of acute trauma or (3) the patient had been pronounced dead by a physician before artificial respiration was started. Thirty minutes was selected as the maximum interval between cessation of breathing and the start of artificial respiration, although a maximum of more than fifteen minutes is probably not consistent with physiologic evidence. A thirty minute limit was chosen because, owing to the emergency nature of the cases reported and the inherent confusion which naturally results, errors of as much as 100 per cent could easily be expected in the estimation of time by onlookers or participants and because periods of more than thirty minutes have been reported in the literature. Cardiac causes accounted for more than half (56.1 per cent) of the 1,446 cases reported in this table. The other relatively common causes were immersion 118 (8.2 per cent), asphyxia neonatorum 97 (6.7 per cent), suffocation 42 (2.9 per cent) and carbon monoxide poisoning 40 (2.8 per cent). Less common causes were electric shock, acute respiratory infections, stroke and asthma. Miscellaneous causes, occurring less frequently than thirteen times each, were pulmonary embolism, diabetes, leukemia, carcinoma, anesthesia, acute alcoholism, cyanide poisoning, uremia, enlarged thymus and depressant drugs. Use of the resuscitator was the most frequent method employed. The second most frequent method was the use of the resuscitator preceded by the Schafer method. This represents instances in which a passer-by had

9 Bates, G. Modern Resuscitation Procedures, Hospitals 11: 46-50 (March) 1940. Bates, G.; Gaby, R. E., and MacLachlan, W. Need for Prolonged Artificial Respiration in Drowning, Asphyxiation and Electric Shock. Canad. M. A. J. 39: 120-125 (Aug.) 1938.

started the Schafer method and firemen subsequently took over with a resuscitator.

Table 5 is a composite of tables 2 and 4. It includes all deaths and all cases of nonbreathing in which survival occurred. Examination of this table gives one an idea of the survival rate for each cause of asphyxia. The survival rate in this series is poorest for cases of electric shock: no survivals, 16 deaths. The rate is also very poor for cardiac cases: 1 survival to 42.7 deaths. The highest survival rate is for cases of asphyxia neonatorum: 1 survival to 1.2 deaths. The rate for the other common causes of asphyxia are immersion, 1 to

accounting to a great extent for the poor survival rate in this group.

Calculation of the relative survival rates for the different methods of resuscitation has not been attempted because there are too few cases in which the method of resuscitation can be assumed to be the only significant variable. It is only in cases of immersion that there are enough data to permit any type of comparison. In 82 cases of immersion in which the Schafer method was used there were 35 survivals. In 44 cases of immersion in which a resuscitator was used there were only 2 survivals: in both of the successful cases the Schafer

2.7; carbon monoxide poisoning, 1 to 2.2; suffocation, 1 to 10.5. These rates are undoubtedly a function of the circumstances surrounding each type of case as well as of the cause of asphyxia itself. The high survival rate of cases of asphyxia neonatorum can thus largely be attributed to the fact that here the time interval between asphyxia and treatment is minimal. In contrast to this is the group of cases of suffocation. A typical case here is that of an infant found in bed smothered by its pillow or blanket. The mother had usually put the child to bed some hours previously, and there is no way of getting more than a very rough estimate of the time between cessation of respiration and start of treatment. Undoubtedly most of these children were dead before treatment was started,

method was used prior to the use of the resuscitator. It seems probable that much of this apparent superiority of the Schafer method in cases of immersion is due to the fact that no precious seconds were wasted in waiting for the arrival of a mechanical apparatus. It cannot be emphasized too strongly that an asphyxiated person must have artificial respiration at once. Waiting for a machine, however efficient, may be fatal.

COMMENT

Before attempting to summarize results or draw conclusions, it should be pointed out that there are two features of this survey which weaken it considerably. The first of these is the paucity of data regarding the lapse of time between asphyxia and the start of treat-

ment. Although these data were asked for in all cases, this information was included in less than half of our reports. The data from the Los Angeles Fire Department is poorest in this respect, for its routine form does not contain a question regarding the lapse of time between asphyxia and the start of treatment. The second weakness in this survey is the lack of autopsy reports. Such information would have been quite helpful in determining the incidence of such pathologic conditions as pulmonary emphysema or fractured ribs, which might be attributable to some form of artificial respiration.

SUMMARY

1. Reports of cases of artificial respiration have been collected from the United States Coast Guard and from the Chicago, Los Angeles and Detroit fire departments during the years 1940 through 1944. These organizations sent in reports on all cases, regardless of whether or not resuscitation occurred. A total of 3,352 reports were obtained.

2. There are reported 153 cases of acute asphyxia in which a resuscitator, a mechanical device for artificial respiration employing alternate blowing and sucking, resulted in revival. None of the patients, 80 of

Physicians were present in virtually all cases, and it was they who made the diagnoses. In only a few cases, however, was a physician present at the start of treatment. The life-saving crew arrived on the scene, as a rule, at least fifteen to twenty minutes before the physician.

Although the gross total of case reports appears impressive (3,352), the number of cases of actual resuscitation is quite small (227) in comparison to the number of different causes of asphyxia (over 11) and the number of different methods of artificial respiration used (10). The fact that in over 60 per cent of the cases revival was achieved by a single method (resuscitator) and that more than half of these cases were those of a single type of asphyxia (asphyxia neonatorum) further shows that statistical analysis is not feasible.

whom were newborn infants, showed evidence of injury as a result of this procedure.

3. There are reported 58 cases of acute asphyxia in which the Schafer prone pressure method was successful in resuscitation. In none of these cases nor in any of the additional 328 cases in which the Schafer prone pressure method was used either entirely or in part was there any report of fractured ribs. Such injuries have been said to be a possible result of improper use of this method.

4. No instance of revival was reported in which more than fifteen minutes elapsed between the cessation of breathing and the start of artificial respiration.

5. Victims of heart disease make up a large portion of the cases treated by the inhalator squads of the Chicago, Los Angeles and Detroit fire departments.

THE BUSH REPORT ON SCIENTIFIC RESEARCH

In the Organization Section in this issue of THE JOURNAL appears the report of a special committee appointed by the Committee on Postwar Medical Service to consider the various proposals that have been made for the aid of research through the granting of funds by the federal government. In a previous issue of THE JOURNAL an abstract was published of the various measures to achieve this end, including the bills proposed by Senators Kilgore, Magnuson and Byrd. Among the points emphasized by practically every medical group that has considered the problem are the following:

1. Voluntary philanthropic foundations, universities and similar agencies have contributed greatly to scientific and particularly to medical research in the United States. The establishment of a federal agency with vast funds might well obstruct, if not destroy, such voluntary efforts and thereby do more harm than good.

2. The federal government aids research on cancer and on tuberculosis as well as research on some other conditions by special grants of funds. Measures have been introduced into the Congress for the spending of enormous funds, particularly in relationship to the study of neuropsychiatric disorders and dental conditions. Any program developed by the federal government should take into account the desirability of coordinating and integrating research on all medical problems proportionately to the need for such research and to the importance of the problems to be investigated.

3. The advancement of medical science and the improvement in health in recent years have been so great that both Presidents Roosevelt and Truman emphasized the medical aspects of research in their messages to the Congress. Nevertheless some of the measures that have been proposed for establishing a National Research Foundation fail to make provision

for direct representation of medicine in the governing boards to be established, leaving it rather to subcommittees to undertake consideration of the medical problems.

4. Most of the measures that have been introduced provide for fellowships to encourage young men who seem to have aptitude for research and for sections to be devoted to the dissemination of information and knowledge that may be developed. From the point of view of medicine there should be coordination between the special agencies created for education and for the dissemination of information with the agencies created specifically for research and also with the central board.

5. The question of patents constitutes a special problem. Discussion of ownership of patents and the licensing of manufacturers under such patents may well come to be the stumbling block over which the whole proposal may fall.

Possibly the ideal concept for the control of a National Research Foundation such as is proposed would be the creation of a general controlling board to include a chairman and members who would themselves be chairmen of various subsidiary committees. By such a technique adequate representation of each of the interests concerned would be provided and with it better coordination for the management of the Research Foundation.

KETOSIS

Formerly physiologists believed that ketone body formation was an abnormal metabolic process due to incomplete combustion of fatty acids and that it was necessary to metabolize carbohydrates in order to utilize the ketone bodies completely. As a result of the work of Mirsky, Soskin, Somogyi and others this concept has been questioned in recent years. Evidence exists that ketone bodies are metabolites which are normally present in the animal organism; when there is an increased production, acidosis results. Early workers showed by means of the tissue slice technic, by perfusion and by experiments on intact animals that ketone bodies are produced only by the liver but cannot be utilized by this tissue. Extrahepatic tissue, particularly muscle, can utilize a certain amount of acetone bodies for the production of energy, on which process insulin exerts little, if any, influence.¹

Ketone bodies and ketosuria are usually associated with the acidosis of diabetes mellitus. The association of a high sugar content of the blood with ketosuria was a logical sequence of the old theory of ketosis. Studies carried out by Waters, Fletcher and Mirsky,² using a

1. Mirsky, I. Arthur: The Etiology of Diabetic Acidosis, J. A. M. A. 118: 690 (Feb. 28) 1942.
2. Waters, E. T.; Fletcher, J. P., and Mirsky, I. A.: Am. J. Physiol. 122: 542, 1938

heart-lung preparation. when the amount of glucose and ketone bodies in the blood could be regulated at will, have shown conclusively that glucose is not necessary for the metabolism of ketone bodies. The fact that insulin can reduce ketosis and still not increase the utilization of ketone bodies in extrahepatic tissue leaves only the possibility that insulin prevents the formation of increased amounts of ketone bodies by the liver.

The liver of a diabetic animal is known to be depleted in glycogen; one explanation of the antiketogenic action of insulin is that the production of ketone bodies occurs whenever the liver is depleted of glycogen. This results in an increased fat metabolism and a resulting increase in ketone body formation. Somogyi² recently presented evidence that the feeding of carbohydrate to normal persons reduces the level of ketones of the blood. This effect is attributed to the fat and protein sparing effect of carbohydrates. When the body is burning carbohydrates it is not metabolizing as much fat, and a resulting decrease in ketone body formation results. Somogyi⁴ presents the thesis that the concentration of ketones in the blood is governed by four factors, two tending to increase it and two tending to reduce it. The factors which tend to increase the level of ketones of the blood are deglycogenation of the liver and decrease in the rate of ketone body utilization by the peripheral tissue. The factors which tend to decrease the level of ketones in the blood are increased utilization of carbohydrates by the liver and increased rate of utilization of ketone bodies by the peripheral tissue. These postulates are supported by Drey,⁵ who showed a transient ketosuria in association with aglucosuria in patients made hypoglycemic by overdoses of insulin. The concept is brought forth that insulin may be either ketogenic or antiketogenic. When insulin is given in such amounts that hypoglycemia results there is a reduction of the glycogen stores in the liver, since there is a tendency to maintain the glucose level of the blood. Concurrent with the low liver glycogen there is an increased metabolism of fat by the liver and a resulting ketonemia and ketosuria. On the other hand, if insulin is given in amounts sufficient to halt glycogenolysis there will be an increased carbohydrate utilization by the liver and a resulting decrease in fat oxidation, which will reduce the amount of ketone bodies produced. Thus, in man, ketonuria and aglucosuria may be present at the same time; it appears that ketonemia and ketosuria are normal physiologic responses to a lack of carbohydrate and an increased fat metabolism in the liver.

As more is known of the intermediary metabolism of foodstuffs, more precise knowledge will be had of both normal and pathologic metabolic processes. This will be of value to the clinician in the diagnosis and rational treatment of metabolic diseases.

THE ORIGIN OF VIRUS

In its restricted sense the term "virus" is applied to agents of disease which so far as known do not multiply in any medium other than living cells of a susceptible host and which pass through standard filters holding back bacteria. Burnet¹ has reviewed the speculations concerning the origin of viruses and their relations to other forms of life. One hypothesis assumes that viruses may be fragments from cells of high forms, footloose genes which have found ways of surviving by passage from host to host; definite evidence of any such process has not been advanced. Another possibility is that viruses are descendants of precellular forms of life which failed to survive except through the adoption of a strictly parasitic, intracellular existence. Filtrable saprophytes have been described the relationship of which to virus awaits investigation.

The dominant view of the origin of viruses is that they are degraded descendants of larger pathogenic microbes as suggested by the range of visible forms between bacteria and certain viruses. Rickettsias and the psittacosis viruses resemble bacteria in several ways, but their requirements for growth are those of viruses. In the case of the smallest viruses the resemblances to bacteria are not at all so striking. Other possible sources of viruses may be fungi, protozoa and spirochetes. This latest view of the origin of virus assumes that the loss of the power of chemical synthesis on part of the descendent units was associated with adaptation to an intracellular environment in which synthetic power is not required for indefinite survival in successive hosts. This implies that viruses, with as well as without vectors, like other living beings, have intricate evolutionary histories.

Burnet writes "We can state dogmatically that there is no evidence whatever that any virus, whether its host be animal, plant or bacterium, arises *de novo*. Every virus particle like any other organism derives by genetic descent from some similar particle and in its turn possesses the power to produce under appropriate conditions replicas of itself." Medical practice, public health work and present investigation are firmly based on the principle that virus diseases breed as true to type as other infectious diseases.

Current Comment

CLASSIFIED ADVERTISING FOR VETERAN PHYSICIANS

At a recent meeting of the Board of Trustees of the American Medical Association in Chicago it was decided to offer without charge to every physician in the military service who was honorably discharged the opportunity to place a classified advertisement in the columns of *THE JOURNAL* devoted to this purpose. Such advertisements will be limited to one insertion of thirty-five words but may be devoted to the search for an assistantship or a residency, to a search for partnerships or space in an office, or to any of the other general headings listed regularly in the classified columns of *THE JOURNAL*. The advertisements will, of course, be limited by the same rules that now apply to all classified advertising. They will be inserted under the appropriate headings in this department of *THE JOURNAL*. The opportunity for such utilization of the classified advertising columns will continue until Dec. 31, 1945.

HEALTH EDUCATION AND VENEREAL DISEASE

The Army's experience with 8,000,000 men has provided an unusual opportunity to evaluate the effect of health education on the prevention of venereal disease. According to Larimore and Sternberg,¹ the Army venereal disease educational program has applied virtually all of the accepted technics of health education. During 1944 the amount of graphic educational material distributed among the troops amounted to 15,000,000 pieces, and film audiences totaled 10,000,000. The program of instruction followed two lines: (1) to impart technical knowledge about venereal disease and (2) to motivate the individual to utilize this information at the time needed for the avoidance of venereal disease. Certain principles have been found essential for the successful use of education. Chief among these are (a) an integrated program, (b) the highest possible quality and attractiveness of all educational materials, (c) abandonment of the pedagogic concept of health education and substitution of a new approach of "health advertising," (d) avoidance of overemphasis of sex and (e) technical accuracy of all materials. It was easier to impart technical knowledge than to motivate the individual to utilize it. The following factors in motivation have been employed and have been found to be effective: fear, intelligence, pride, patriotism. Among the reasons for failure of motivation were (a) the nature of the sex urge itself, (b) "education for venereal disease" afforded by sexy motion pictures, comic strips, pin-up girls and the use of sex in certain advertising,

(c) "war psychology," (d) displacement of normal family and social relationships, (e) newer methods of treatment, (f) alcohol and (g) the state of morale. The strictly moral approach to the problem of avoiding venereal disease has been relatively ineffective in the Army. In measuring the results of the program, the authors state that the best single criterion is the extent of utilization of prophylaxis, which at the present time is at the rate of more than fifty million individual prophylactic items per month.

SEMEN ANALYSIS AND MALE FERTILITY

The discovery of a cause for sterility in the wife constitutes insufficient evidence for attributing the reason for the sterile marriage to that partner exclusively. As pointed out by Harvey and Jackson¹ after an extensive study of the value of semen analysis in the assessment of male fertility, both partners are involved in a high proportion of sterile marriages. Only when the husband's semen is fully examined and classified can this factor of subfertility in the male partner be appropriately evaluated. This report from the Exeter Sterility Clinic in England indicates that there are four main factors in semen analysis which influence fertility. For one of these—density—they believe that a figure of 50 million sperm per cubic centimeter can be accepted as a reasonably satisfactory minimum with the technic employed. The morphology of the sperm is also important; abnormalities can occur in the head, middle piece or tail. Abnormal morphologic types may appear in the seminal fluid as a result of imperfect spermatogenesis, arrest of spermateliosis at an early stage with premature detachment from the germinal epithelium, or degeneration of originally normal sperm. Harvey and Jackson describe a technic by which the percentage of fully motile and feebly motile sperm can be readily calculated. By observing the rate of decreasing motility at various intervals, the viability of sperm can be expressed in a manner which also permits fertility to be roughly graded. Whether density or total sperm count gives the better index of fertility is uncertain. The authors believe that male subfertility does not become of primary importance unless the results of the semen analysis fall below minimal values in all four of these criteria. The Exeter report is based on analysis of the semen of 324 husbands of subfertile marriages, in 236 of whom the examinations were carried out according to the detailed methods described in the paper. The technics are so complex that they cannot be readily duplicated in a physician's office; considerable equipment and expert technical skill are necessary. This work and others of a like nature, however, furnish important basic knowledge on the factors involved in the treatment of the sterile or subfertile marriage.

MEDICINE AND THE WAR

ARMY

SAFE AND EFFICIENT USE OF DDT

A bulletin was recently published by the Army as a technical guide for the safe and efficient use of DDT. The publication contains information on the precautions to be taken in handling DDT, its mode of action in insect control and the proper methods of application.

It is emphasized that, although DDT may be safely handled as an insecticide, it is nevertheless a toxic material. Poisoning may occur from ingestion of DDT solutions through the skin. DDT powder and aerosols are not absorbed through the skin and have been found to produce no ill effects when inhaled in small amounts. However, in conditions in which air currents do not carry away the dust from the user, it is wise to wear suitable respirators as protection against excessive inhalation.

DDT acts on insects both as a contact poison and as a stomach poison. Studies have shown that the poisonous effect of DDT on mosquito larvae is fully as powerful as that on the adult insect, although on some other insects, such as flies, the larvae are not equally affected by the insecticide. For the extermination of insects such as ants, roaches, fleas, bedbugs and flies, DDT oil solution or powder should be used, with particular attention to cracks, holes and seams in walls, floors and bedding, as indicated. One of the most valuable characteristics of DDT lies in its tendency to remain deadly to insects over a prolonged period. In applying DDT solutions to walls and other large surface areas, a coarse spray is usually employed, but in applying it to screens or mesh surfaces ordinary paint brushes may be used. Although the effectiveness of the treated areas against insects persists for some time, the insects which come in contact with the chemical may not die until an hour or more has elapsed, and immediate death should not be expected.

Although rapid progress has been made in the development of DDT since it first made its appearance in the field of science, much remains to be learned before its full potentialities in insect control can be realized. Investigation is continuing on every aspect of DDT, however, in search of new and extensive improvements in everything from its chemical beginning to its final application in the field.

MERITORIOUS SERVICE UNIT AWARD

The Meritorious Service Unit Award was recently given to the 25th AAF Base Unit (AAF Medical Service Training School), Robins Field, Ga., "for outstanding devotion to duty in the performance of exceptionally difficult tasks during the period Nov. 10, 1944 through May 31, 1945. During this period," said the citation, "the personnel of the 25th AAF Base Unit performed in an outstanding manner in accomplishing its mission of casual and unit training. In addition; this unit greatly contributed to furthering medical training and sanitation for the Army Air Forces by preparing many unique training aids and devices. The high standard of discipline and superior performance of duty displayed by the members of the 25th AAF Base Unit reflect highest credit on the organization and the Army Air Forces of the United States." Lieut. Col. Norbert B. Reicher, M. C., Syracuse, N. Y., is the commanding officer of the school, and Major Thomas E. Rardin, M. C., Columbus, Ohio, the director of training.

DENTAL CORPS OFFICER AWARDED

Members of the Army Nurse Corps have been awarded 1,008 decorations since Dec. 7, 1941, 2 Distinguished Flying Crosses (one posthumous award), 4 Silver Stars for gallantry in action (one posthumous award), 12 Legion of Merit awards, 433 Bronze Stars or Oak Leaf Clusters in lieu thereof, 388 Air Medals or Oak Leaf Clusters in lieu thereof, 5 Soldier's Medals and 60 Purple Hearts (15 posthumous), 103 unit citations or recommendations having been reported to date.

ARMY AWARDS AND COMMENDATIONS

Lieutenant Colonel James E. Kendrick

The Air Medal and the Bronze Star were recently awarded to Lieut. Col. James E. Kendrick, formerly of Greenville, Ala., for service with the 10th Air Force, of which he was assistant staff surgeon and then staff surgeon. The citation which accompanied the Air Medal stated that "on April 6, 1944 Lieutenant Colonel Kendrick volunteered for a hazardous type of flight in an amphibious aircraft to the Bay of Bengal. At the time he knew that this flight would go considerable distance along the coast of enemy territory and that the type of aircraft in which he was flying was subject to easy interception. This aircraft landed and took aboard 9 injured members of a combat crew, to whom Lieut. Col. Kendrick gave medical treatment. His conduct reflects great credit on himself and the Army Air Forces." Accompanying the Bronze Star was a citation "for meritorious service from Nov. 11, 1943 to Aug. 7, 1944. As assistant staff surgeon and later staff surgeon of the 10th Air Force, Lieutenant Colonel Kendrick rendered such exceptional service, in the conduct of medical matters as to improve substantially the standards of health and sanitation within this command. By his constant display of industry and medical knowledge the morale and operations of the 10th Air Force were benefited in a high degree. His meritorious service reflects credit on himself and on the Army Air Forces of the United States." Dr. Kendrick graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1933 and entered the service Jan. 28, 1941.

Major Israel Weinstein

Major Israel Weinstein, formerly of New York, was recently awarded the Bronze Star "for meritorious service in combat from March 11 to May 8, 1945 in France, Germany and Austria. As division medical inspector Major Weinstein gave unstintingly of his effort to supervise the health and sanitation of front line troops. He unhesitatingly and with complete disregard of his own safety rode through woods occupied by enemy snipers to reach his destination. On April 26 on the north shore of the Danube between Regensburg and Donauwörth, while on his way to see that a satisfactory water point was set up for an advanced detachment of soldiers, he came under heavy mortar fire. Both he and his driver were wounded. His first concern was to give medical aid to the wounded driver. Major Weinstein's ceaseless effort in guarding the health and welfare of the troops has brought credit to himself and reflects the highest tradition of the armed forces." Dr. Weinstein graduated from Columbia University College of Physicians and Surgeons, New York, in 1926 and entered the service Aug. 28, 1942.

Lieutenant Colonel Earle I. Greene

Lieut. Col. Earle I. Greene, formerly of Chicago, was recently awarded the Bronze Star "for meritorious service in connection with military operations as chief of surgical service, 35th Station Hospital, European Theater of Operations, from July 15, 1943 to May 8, 1945. By virtue of his professional qualifications, his superior effort and insistence on maximum performance, Lieutenant Colonel Greene was responsible for the establishment of a surgical service in which the highest professional standards prevailed. During one emergency he personally operated on the more seriously wounded for seventy-two successive hours and saved many lives. His professional judgment has been admirably coupled with extreme devotion to duty and tireless energy, leading to the increased welfare and recovery of several thousand patients." Dr. Greene graduated from Rush Medical College, Chicago, in 1923 and entered the service Feb. 15, 1942. He is at present attached to the surgical service of the 120th Station Hospital.

Colonel Martin E. Griffin

Col. Martin E. Griffin, Washington, D. C., was recently awarded the Legion of Merit for his direction of medical supply activities in Italy. As director of the medical supply branch, public health subcommission, Allied Commission, Colonel Griffin was responsible for the planning, organization and application of medical supply techniques from Jan. 1, 1944 to July 31, 1945. The citation said, in part, "Despite the handicap of limited equipment and personnel, Colonel Griffin installed a medical supply system for the Italian civilian population and established numerous medical supply depots throughout Italy. In addition he reestablished production in several Italian pharmaceutical plants, which resulted in a constantly available supply of drugs and serums to combat many dangerous and infectious diseases." Dr. Griffin graduated from the State University of Iowa College of Medicine, Iowa City, in 1925 and entered the service July 1, 1926. In recognition of his services to the Italian government, Dr. Griffin was recently awarded the Cross of Knight Commander, Order of the Crown of Italy, by Crown Prince Umberto.

Lieutenant Colonel Roy V. Boedeker

Lieut. Col. Roy V. Boedeker, formerly of St. Louis, was recently awarded the Bronze Star for meritorious achievement in connection with military operations in the Mediterranean Theater of Operations from Oct. 27, 1943 to March 11, 1945. The citation accompanying the award reads, in part, "As assistant chief of the surgical service of the 70th General Hospital, Lieutenant Colonel Boedeker demonstrated superior performance of outstanding services under the most trying conditions in both North Africa and Italy. The efficiency of the policies inaugurated by the technical and organizational ability of Lieutenant Colonel Boedeker early in the establishment of the hospital were the basis on which all departments of the surgical service operated with maximum effectiveness. Because of the wide range of his military experience, Lieu-

tenant Colonel Boedeker was frequently assigned such tedious tasks as trial judge advocate, summary court officer and plans and training officer and administered the duties involved in each in an outstanding manner, reflecting credit on himself and on the military service." Dr. Boedeker graduated from St. Louis University School of Medicine in 1935 and entered the service July 29, 1941.

Major Morris L. Grover

Major Morris L. Grover, formerly of Providence, R. I., was recently awarded the Bronze Star "for meritorious service in connection with military operations against an enemy of the United States from April 2, 1945 to May 8, 1945 in Germany. Major Grover, division medical inspector, performed his duties in an outstanding manner. Through his professional skill and constant perseverance, disease epidemics were prevented from spreading in stockades peopled by thousands of enemy prisoners of war and displaced persons. On frequent occasions Major Grover disdained enemy fire to assure the maintenance of supply discipline in relation to medical material. The meritorious service of Major Grover is in keeping with the highest traditions of the armed forces." Dr. Grover graduated from Tufts College Medical School, Boston, in 1928 and entered the service Sept. 20, 1941.

Captain Robert Blatherwick

The Bronze Star was recently awarded to Capt. Robert Blatherwick, formerly of Van Hook, N. D. According to the citation accompanying the award, "as assistant American surgeon at the Szubin, Germany, prisoner of war camp from October 1944 to January 1945 he displayed marked devotion to duty and high professional skill in conserving the health and improving the well-being of many hundreds of American officer prisoners of war." Dr. Blatherwick graduated from Northwestern University Medical School, Chicago, in 1943 and entered the service July 13, 1943.

MISCELLANEOUS**DRS. BLAKE AND MAXCY RECEIVE
TYPHUS AWARD**

The United States of America Typhus Commission Medal was awarded at the Office of the Surgeon General, September 10, to Dr. Francis G. Blake, dean of Yale University School of Medicine, and Dr. Kenneth F. Maxcy, professor of epidemiology at Johns Hopkins School of Hygiene and Public Health, for "exceptionally meritorious service." Both Dr. Blake and Dr. Maxcy, in addition to their other duties, are consultants to the Secretary of War.

The citation accompanying the award to Dr. Blake said, in part, "Dr. Blake initiated and directed investigations of classic importance on the clinical features and prevention of scrub typhus. He made new contributions to the knowledge and control of a form of typhus fever of great military and civilian importance. His wisdom, energy and special competence assured the success of this mission and laid the basis for enduring benefits."

Dr. Maxcy was commended for "his observations made in the field under difficult campaign conditions, which clarified earlier knowledge of the conditions under which this disease occurs and added greatly to information about the special conditions which were making this disease a health hazard of paramount importance to American troops."

lems he has encountered. On September 20 the Limb Manufacturers were represented and the medical director of the Disabled American Veterans made a further presentation for that organization.

**UNRRA AND GREEK GOVERNMENT
PLAN FEEDING CENTERS**

A special plan with UNRRA and the Greek government for the feeding of 1,000,000 people was recently dispatched to the headquarters of the United Nations Relief and Rehabilitation Administration. The feeding plan calls for assisting children from birth to 16 years of age and nursing mothers, and the feeding centers are to be established through the country.

These feeding centers will be administered by the Patriotic Foundation, with a general committee in charge. In order to provide a well balanced meal of 600 calories a day, UNRRA will supply the basic food. Meanwhile the Greek War Relief Association will supplement this with other specially imported foods and with local produce purchased out of a sum of \$1,370,000 set aside for this purpose.

The idea is not merely to feed the children and mothers 600 calories a day but to insure that they get a diet rich in vitamins and minerals to overcome the effects of malnutrition from which they are suffering. In order to enrich these diets three trained dietitians, under the supervision of UNRRA, have already gone into the provinces. These experts will train local cooks in the use of the basic foods supplied by UNRRA, so that they may be adapted to Greek recipes and prepared so as to preserve their nutriment.

To carry out this project, a large staff of competent personnel will be required. This will include 11 UNRRA regional representatives, who will act as liaison officers and advise the 39 provincial supervisors, 120 assistant supervisors and 35 clerical assistants, all local personnel, whose salaries will be paid by the Greek War Relief Association.

AID TO PHYSICALLY HANDICAPPED

Augustine B. Kelley, chairman of the Committee on Labor's Subcommittee on Aid to Physically Handicapped, recently announced a continuation of hearings on the problems of persons who have suffered amputations. The hearing on September 19 included a round table discussion between members of Congress and patients from the Walter Reed Hospital Amputation Center. The War Department showed a film, and a civilian wearer of an artificial limb discussed some of the prob-

ORGANIZATION SECTION

REPORTS OF OFFICERS

NOTE.—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion. The Report of the Secretary, additional sections of the Report of the Board of Trustees and reports of some councils, bureaus and departments will appear in subsequent issues of The Journal.—Ed.

(Continued from page 367)

Bureau of Investigation

The Bureau of Investigation, by the constant collection and distribution of information, has continued its efforts to promote the educational activities of the Association. Physicians, government agencies, federal, state and municipal authorities, radio stations, newspapers and magazines, Better Business Bureaus, civic and welfare organizations, Red Cross home nursing classes, research workers, teachers, students and laymen in general continue to seek information available in the Bureau's files.

INQUIRIES

Inquiries from these many sources showed an increase over those of 1944. Most numerous were those received from newspapers and magazines, from students in grammar schools, high schools and colleges seeking material on consumer problems and from cadet nurses and Red Cross home nursing classes. These inquiries indicate that the work of the Bureau is attracting the interest of a wider section of the public. These inquirers have sought information not only on "patent medicines" and quacks and fads of many varieties but also on statistical data and bibliographies on other matters of consumer interest.

Many requests for information and counsel have come from publishers of newspapers and magazines or from their advertising departments. Many such requests have come from farm journals. Three of the leading Chicago newspapers frequently call on the Bureau for information.

The Better Business Bureaus of the country turn to the Bureau of Investigation for aid that will enable them to serve their members and the public, and their inquiries and suggestions make it possible for the Bureau to develop important new material for its files.

County and state medical societies have continued to call on the Bureau for information about or investigation of matters that have come to their attention. The assistance of these societies in furnishing the Bureau with data on such matters has been deeply appreciated, as has the cooperation of many other agencies.

Teachers and their pupils in large numbers have sought and received the Bureau's material on "patent medicines" and charlatans in connection with their study of consumer problems and have made it clear that much of this particular material is not obtainable elsewhere. Physicians continue to inquire about questionable practitioners and about dubious methods of treatment brought to their attention by patients. The general lay public, as before, has itself sent in many such inquiries. Many inquiries, particularly those from students, dealt with more than one item, and some of them included long lists, as indicated by the fact that 3,000 inquiries pertained to 4,600 separate subjects. Among the leading subjects of inquiry in 1944 were diabetes "cures," vitamin preparations, aspirin, so-called "alkalizers," laxatives, cancer "cures" and various products that are widely advertised over the radio and in the lay press.

OTHER ACTIVITIES

The Bureau prepared a total of forty-one articles for THE JOURNAL, including seventeen presentations of abstracts of one hundred and twenty-seven Notices of Judgment issued by the

Food and Drug Administration, three presentations of abstracts of twenty-five Cease and Desist Orders and fifteen of abstracts of one hundred and six stipulations by the Federal Trade Commission. There also were five articles presenting abstracts of nine fraud orders issued by the United States Post Office Department.

The distribution of pamphlets and of the book *Nostrums and Quackery and Pseudo-Medicine* was continued as in previous years, and physicians and educators were provided with the Bureau's slides on nostrums and quackery for educational purposes.

The Bureau has continued its cooperation with the Post Office Department, the Federal Trade Commission and the Food and Drug Administration.

Bureau of Exhibits

The Bureau of Exhibits is concerned primarily with graduate medical instruction and secondarily with health education of the public. During the year 1944 the Bureau cooperated in meetings in forty-one states and in the District of Columbia. There was a pronounced increase in requests from the armed forces and, as in the past, such requests were given special consideration. Because of the war it was not possible to comply with requests outside the limits of the continental United States.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the Chicago session emphasized war medicine. The United States Army, the United States Navy and the United States Army Air Forces not only presented noteworthy exhibits of their own but lent generous aid in men and materials to other features of the meeting. Many medical officers from the armed forces and from the United States Public Health Service showed their own exhibits dealing with war problems. An excellent group of exhibits on tropical medicine caused much favorable comment, while exhibits on industrial health in wartime were extensively displayed.

There were four special exhibits sponsored by the Committee on Scientific Exhibit of the Board of Trustees. The special exhibit on fractures, under the guidance of a committee headed by Dr. Kellogg Speed, was as popular as ever. A group of soldiers from Camp Grant acted as patients in the demonstrations. The special exhibit on the treatment of burns was presented by a committee consisting of Dr. Stanley J. Seeger, chairman; Capt. Ernest W. Brown (MC), U. S. Navy, and Capt. Joseph E. Hamilton, M. C., A. U. S. The exhibit covered all phases of the treatment of burns. The special exhibit on chemotherapy and infectious diseases was presented by a committee of which Dr. Chester S. Keefer was chairman. The subject of tropical diseases, arranged with the help of Dr. Henry E. Meleney, another member of the committee, received much emphasis. A group of physicians who had spent many years in the tropics demonstrated in this exhibit throughout the week. The special exhibit on rehabilitation was presented by the Council on Industrial Health and the Council on Physical Medicine of the American Medical Association with the assistance of representatives of the Army, Navy, Veterans Administration and Federal Security Agency.

Each of the sixteen sections of the Scientific Assembly sponsored groups of exhibits dealing with the various specialties of medicine. The total number of these exhibits was much smaller than usual because of the limitation of exhibit space in the Palmer House, but the caliber of the exhibits that were shown was very high. Great credit is due those exhibitors who, under the difficulties of wartime, were able to assemble so much excellent material. The emphasis of the exhibits was placed, as usual, on the problems of the physician in general practice rather than on the interests of the specialist. The section representatives to the Scientific Exhibit deserve special mention for their assistance.

Motion pictures were shown in the Casino at the Morrison Hotel, three blocks from the Scientific Exhibit at the Palmer House. There was but one motion picture theater, and most of the films were presented twice during the week. As in previous years, no films were shown in exhibitors' booths.

The Committee on Awards, of which Dr. Vincent W. Archer was chairman, performed its task conscientiously and with credit. Twenty-three awards were made, including six medals, eight certificates of merit and eight honorable mentions. One certificate of appreciation was awarded to an exhibit from Brazil.

An interesting trend in graduate medical instruction is indicated by the question and answer conferences. At the Chicago session there were two of these in rooms adjoining the exhibit hall. Rheumatic fever was presented under the auspices of the Section on Pediatrics in cooperation with the Rheumatic Fever Committee of the American Academy of Pediatrics. Heart and peripheral vascular disease was conducted by the Section on Practice of Medicine in cooperation with the American Heart Association. Consultants were on duty in each conference room, on a prearranged schedule, during the entire week. So popular were these conferences that requests have been received for half a dozen such conference rooms on various subjects at the next annual session.

ASSOCIATION EXHIBITS

Graduate medical instruction through the use of exhibits still further increased during 1944. The demand exceeded all previous years. Some of the requests could not be complied with because the exhibits were already reserved for other occasions, while several of the meetings for which material had been reserved were canceled. There were seventy-one exhibits sent to thirty-six meetings of medical and scientific organizations. The Director of the Bureau either attended the meetings personally or made arrangements for an attendant from the American Medical Association staff or otherwise.

Health education was promoted with thirty-three exhibits at twenty-five meetings, fairs and expositions. The cancellation of most of the large fairs and expositions reduced the activity to the lowest level in several years. The difficulty of transporting the exhibits by freight and express was an additional factor interfering with this activity.

The total number of exhibits available for loan is fifty-four. During the year nine new exhibits were made and ten old ones discontinued.

MOTION PICTURES

The demand for motion pictures has exceeded all previous years. Additional copies of old films, together with a few new ones, have made it possible to send out 575 pictures to 333 meetings, the chief recipients being army camps, medical schools, hospitals and county medical societies. There are now twenty-seven films in the motion picture library, three old ones having been dropped during the year and five new ones added. Reservations are often made months in advance, and most of the films are booked as often as the difficulties of transportation will allow. The secretary of the Bureau has continued the good work she has been doing in the supervision of this activity, and it is due to her efficiency that it has functioned so well.

There have been hundreds of requests for information concerning films distributed by other organizations. Often a physician desires a motion picture on a special subject to fit into the program of the meeting which he is preparing. As far as possible these requests have been complied with, entailing much correspondence.

THE ARMED FORCES

Assistance to the Army, Navy and Air Force were given special consideration. During the year one hundred and forty-eight motion picture films were sent to posts and camps in twenty states for purposes of medical instruction. Health exhibits were lent to the Army on three occasions for the instruction of enlisted personnel. In spite of the exigencies of war, with sudden transfer of officers and other difficulties, this cooperation was carried on as far as facilities would permit.

MUSEUMS

Cooperation with museums has been maintained, with permanent exhibits on health education at the Chicago Museum of Science and Industry, the Cleveland Health Museum and the Toledo Museum of Science. Temporary exhibits have been lent to the Cayuga Museum of History and Art at Auburn, N. Y., while at the Newark Museum at Newark, N. J., as well as at several of the other museums, question and answer files have been on display together with current copies of *HYGEIA*. Question boxes have been continued at the museums in conjunction with the displays. The questions are sent to the American Medical Association and answered by the Bureau of Health Education.

The American Museum of Health, New York, which has in its possession a considerable amount of exhibit material previously shown by the American Medical Association at the New York World's Fair, is still without permanent quarters. However, the exhibit material has been on display in other cities from time to time.

Museums, with their ready made audiences and with rather ideal display facilities, offer a great opportunity for exhibits on health education. County medical societies should not neglect this valuable contact with the public. The Bureau of Exhibits will cooperate with county societies as far as possible.

PUBLICATIONS

The second edition of the book *Fundamentals of Anesthesia* was published during the year. The fifth edition of the *Primer on Fractures* is nearly exhausted, and the Exhibit Committee on Fractures is preparing additional material for a sixth edition.

The pamphlets *Varicose Veins* and *Food Charts* have been revised and reprinted. They still remain popular.

A pamphlet on *Chemotherapy in Infectious Diseases*, prepared by Dr. Chester S. Keefer, Dr. Henry E. Meleney and Dr. Austin E. Smith, in connection with the special exhibit on the same subject, has received wide distribution.

Several pamphlets were prepared and distributed in connection with the special exhibit on burns. The *Local Treatment of Burns*, by Dr. Roy D. McClure and Dr. Conrad R. Lam, *Treatment of Burns: General Care of the Burned Patient*, by Dr. Henry N. Harkins, *Establishment of a Skin Cover Following Thermal Burns*, by Dr. Earl C. Padgett and Dr. John H. Gaskins, *Electric Burns*, by Dr. Hart Ellis Fisher and Dr. George Howard Irwin, have proved popular. The pamphlet *Chemical Burns of the Eye*, prepared by Dr. Alan C. Woods, Dr. William F. Hughes Jr., Dr. Roy O. Schulz and Dr. A. E. Maumenee, was printed but not distributed. Authorization for publication of the material contained therein was first given and then rescinded because of its confidential nature in the war effort.

MISCELLANEOUS ACTIVITIES

The Director of the Bureau has kept in close touch with the various Councils and Bureaus of the Association so that he could properly represent the work of the Association when exhibits were presented at state medical meetings and other occasions.

The Director of the Bureau has served on the National Advisory Council of the Cleveland Health Museum and the Committee on Exhibits of the Society of Illinois Bacteriologists. He has been a member of the Council of the Public Health Education Section, the Committee on Cost Accounting for Health Education and the Committee on Compensation for Public Health Workers of the American Public Health Association. He has lectured at the University of Illinois College of Medicine, where he is assistant professor of bacteriology and public health.

Students in health education both from this country and from the Latin American countries have been given much information concerning exhibits and motion pictures on their visits to Association headquarters.

Conferences have been held during the year with the directors of scientific exhibits of state medical societies concerning the exhibit programs for those societies.

The Bureau also collaborated with the American Academy of Ophthalmology and Otolaryngology in connection with their exhibit program.

Articles have been prepared for *HYGEIA* and book reviews for *THE JOURNAL*.

Bureau of Public Relations

During the past year, the Bureau of Public Relations of the American Medical Association has continued to expand its activities, extending to the medical profession and to the public information regarding the work of the Association and the important progress being made by medical science. This Bureau is not, primarily, one for propaganda. Its activities do induce support of the position of the American Medical Association and of the medical profession by keeping the public fully informed regarding medical affairs and medical progress.

During 1944 the number of individual inquiries coming to the Bureau of Public Relations from newspapers, magazines, radio stations and other mediums of public information totaled more than 5,300, a slight increase over the number received the previous year. This is particularly impressive in view of the concentration of the nation's energies on war work. Many of these inquiries pertained to medical activities other than those directly related to the war, thus demonstrating the effectiveness of the Association's policies in furthering public knowledge regarding medical science. More than 91,000 individual items based on articles that appeared in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* and in *HYGEIA* were published in daily newspapers during the year. This number is estimated on the basis of press clippings received in the headquarters office and represents an increase of approximately 7,000 over 1943. These articles were not as long as the average ones published in newspapers in 1943, owing to space limitations imposed on American newspapers by the paper shortage. Significantly, however, there was an increased use of articles based on information emanating from the Association despite the amount of space being devoted to the war by the American press.

The *AMERICAN MEDICAL ASSOCIATION NEWS*, containing abstracts of articles from *THE JOURNAL* and *HYGEIA*, is sent out by this Bureau to some 1,200 newspapers, press magazines, radio stations, industrial house organs, medical journals and bulletins. This publication, prepared under the supervision of the Editor of *THE JOURNAL*, has become a recognized medium for the dissemination of news pertaining to medical activities and medical progress. All of those receiving it have made specific, voluntary requests to have their names placed on the mailing list.

The aforementioned data regarding inquiries received by this Bureau and articles appearing in newspapers demonstrate that editors, reporters, feature writers, news commentators and managers of radio stations throughout the country look to the headquarters office of the American Medical Association as a dependable source of information regarding medical matters. They have sought information and advice on every phase of the multiple activities of the Association and of the profession. The activities of this Bureau in providing guidance to these people has resulted in a decided decrease of inaccurate information regarding medical matters appearing in the daily press. In hundreds of instances inaccurate information of such a nature has been corrected in process of publication, and in many other hundreds of cases such inaccurate information has been completely eliminated as a result of the advice and service offered by this Bureau.

Direct contact is maintained in Chicago by this Bureau with the headquarters of all the press associations and radio chains, and during 1944 at least two articles concerning material published in *THE JOURNAL* or *HYGEIA* were sent out each week from Chicago on press association wires.

Together with other bureaus and councils of the Association, the Bureau of Public Relations has played a major role in assisting in medical phases of the nation's war activities. Those associated with this Bureau have served as consultants to or members of information and other committees of practically every branch of the federal government in regard to medical phases of the war.

All of these activities have played a vital role in bringing about an understanding on the part of the American people of the contributions being made by the Association and medical science to the public welfare.

REPORT OF THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

To the Members of the House of Delegates of the American Medical Association:

During the past year the major concern of the Council on Medical Education and Hospitals has been with the supply of premedical and medical students.

THE SUPPLY OF PREMEDICAL AND MEDICAL STUDENTS

The trend of events can probably best be visualized by noting certain facts about the composition of students now in medical schools. The third and fourth year classes contain nearly 90 per cent Army and Navy students. The sophomore class contains fewer students in this category, although over 80 per cent of the class are A. S. T. P. and Navy V-12 students. The sharply decreased input of such men into our medical schools is emphasized by the drop in Army and Navy students in the current first year class, which totals about 37 per cent. It was possible for this first year class to be filled primarily because of a temporary Selective Service adjustment. In April 1944 the Selective Service System abolished further occupational deferments of premedical students effective July 1, 1944. The Selective Service System permitted the enrolment of approximately 2,000 students before July 1, 1944 even though some of these men had not completed their premedical training. This adjustment was temporary and, unless regulations are changed, these numbers will not be available under Selective Service deferment for the next entering class in 1945.

It is estimated that Army and Navy students completing their premedical training will fill freshman vacancies in the 1945 entering classes to the extent of approximately 50 per cent of the places. This will virtually deplete the supply of premedical students in the Army and Navy programs so that only approximately 10 per cent of the freshmen places will be filled by students in the Navy program and none of the places by students in the Army program in 1946. This will necessitate selection at that time of 90 per cent of the entering class from civilian sources.

It is highly improbable that medical schools can secure qualified civilian students to fill 50 per cent of the places in the entering classes of 1945, and it is utterly impossible for them to secure 90 per cent of the freshmen from civilian sources in 1946. The civilian sources from which these students must be drawn include women, physically disqualified men and veterans plus perhaps a relatively few students who finish their premedical work before reaching the age of 18. Whether the students in the latter category will be deferred on reaching this age during the medical studies is uncertain. In any case there is general agreement that, should schools be limited to these sources for freshman material, there will result either a pronounced reduction in enrolments or a serious decrease in the quality and qualifications of the entering students.

Even though the entering classes in 1945 should in some way be nearly filled, it is highly important to remember that no premedical students have entered the A. S. T. P. Program since June 1944 and that no students are entering the Navy V-12 premedical program at the present time. In short, there is an utterly inadequate number of premedical students being trained for future admission to medical schools.

All this was foreseen a year ago and presented to the House of Delegates in the last annual report. Taking cognizance of these facts and estimates, the House of Delegates of the

American Medical Association passed the following resolution at its opening session, June 12, 1944:

WHEREAS, The present policy of the Army and the Selective Service System in preventing the enrolment of a sufficient number of qualified medical students will inevitably result in an overall shortage of qualified physicians with imminent danger to the health and well being of our citizens; therefore be it

Resolved, That it is imperative that immediate action be taken by the President or the Congress of the United States to correct the current drastic regulations, which result in a restriction of the number of students qualified to enter the courses of medical instruction in approved medical schools.

* This resolution was sent to the President, the secretaries of War and Navy, the director of Selective Service and all members of the House and Senate military affairs committees. The responses to this communication clearly indicated that the governmental departments and agencies involved were unwilling to make any adjustment.

It seemed apparent that the only remaining approach was to the Congress of the United States. A bill providing for the deferment of appropriate numbers of premedical students was introduced as H. R. 5128 by Representative Louis E. Miller of Missouri. Hearings were never held on this bill.

In the ensuing weeks and months every effort was made in further conferences and communications to bring about the necessary adjustment on the part of Selective Service and the Army and the Navy as well as to bring to the attention of senators and congressmen the alarming seriousness of the situation. An analysis of the problem was made by the Secretary of the Council on Medical Education and Hospitals before the Subcommittee on Wartime Health and Education of the Committee on Education and Labor of the Senate during hearings of that subcommittee pertaining to the health of the nation. Since that time Senator Claude Pepper of Florida has evinced a growing concern over this matter. In February 1945 conferences were held with representatives of Senator Allen J. Ellender of Louisiana, who also has become interested in this problem. At that time agreement was reached as to the general lines which an appropriate legislative measure ought to follow to meet the needs. On Feb. 26, 1945 Senator Ellender introduced into the Senate bill S. 637, which was referred to the Committee on Military Affairs.

The provisions of this bill are generally acceptable to the Council on Medical Education and Hospitals of the American Medical Association and likewise have the full support of the executive council of the Association of American Medical Colleges. Hearings were conducted by the Senate Committee on Military Affairs on May 1, 1945. The Council on Medical Education and Hospitals was represented by Drs. Harvey Stone and Victor Johnson. The bill was opposed by the Army, Navy and Selective Service System. At the time of going to press, the Committee has made no report.

Two days after this bill was introduced the Secretary appeared before the Senate Committee on Education and Labor to make a statement supporting the Hill-Burton Senate Bill 191 providing for hospital construction supported in part by federal funds (see also page 000). In connection with that statement the Secretary again pointed out the inadequacy of the supply of qualified premedical and medical students for future classes and stressed the necessity for passage of a bill carrying the provisions of the Ellender bill. Considerable interest was evinced in this problem and there were indications that the Senate Committee on Education and Labor would support the measure.

It is probable that events subsequent to the publication of this report will necessitate a supplementary report from the Council to the House of Delegates.

THE SUPPLY OF PHYSICIANS

Even if the Ellender bill is passed or appropriate measures of other kinds are instituted to insure a continuation of the supply of premedical and medical students, there is likely to be a considerable reduction in the number of physicians available for civilian medical care after the war. It appears probable that there will be the following increased demand for physicians which did not exist before the war:

Army.—A regular standing army including men enrolled under a compulsory military training program might total 2,000,000 men, requiring 10,000.

Navy.—The peacetime Navy will probably require about 5,000.

Veterans Administration.—Manning the veterans' hospitals may require about 15,000.

Liberated Countries.—The widespread destruction of hospitals and medical schools and casualties among physicians in liberated countries of Europe and in China will require the aid of unknown numbers of physicians from the United States.

Replacement of Casualties.—The number of physicians killed or incapacitated by the war requiring replacement is another unknown quantity.

Total.—The probable number of doctors needed after the war in addition to numbers before the war might be conservatively estimated at more than 30,000.

Even if the numbers of enrolments, admissions and graduates are maintained at the present wartime levels, only about one half of this need would be met. Under the accelerated program of medical education there were 10,357 medical graduates in the two year period from July 1, 1942 (when acceleration started in most medical schools) to June 30, 1944. By June 30, 1945 there will be an additional estimated (by medical schools) 9,844 graduates.

This totals 20,201 graduates during a complete three calendar year cycle involving four graduating classes. If the accelerated program is continued in our medical schools, there will be an additional approximately 20,000 graduates in the ensuing three year cycle from July 1, 1945 to June 30, 1948. During this whole six year period of accelerated medical education there will be a total of approximately 40,000 graduates.

During this same six year period approximately 24,000 physicians have died or will die, since the death rate of civilian physicians is increasing. As a consequence there will be available after the war only some 16,000 additional physicians to meet the estimated increased need of over 30,000. The deficit will be far greater unless there is made some such adjustment as is provided for in the Ellender bill.

THE ACCELERATED PROGRAM IN MEDICAL SCHOOLS

Even though the input of Army and Navy students into our medical schools will sharply decrease, those men who are in the A. S. T. and Navy V-12 programs in medical schools will be continued until graduation. Therefore it is necessary that medical schools continue the accelerated program in accordance with contracts held by the Army and Navy. However, most medical schools plan to return to the plan of annual admissions of medical students. Annual admissions are entirely compatible with acceleration after the student enters medical school. The result will be the completion of the work in three years, although there will be fewer students admitted in any one calendar year. Even though there are annual admissions commencing in 1945 there will necessarily be graduations every nine months until the year 1948, so that the increased numbers of students graduating in the past three years will be maintained in the ensuing three years.

LICENSURE UNDER THE ACCELERATED MEDICAL SCHOOL PROGRAM, THE PREMEDICAL A. S. T. AND NAVY V-12 PROGRAMS, AND THE NINE MONTH INTERNSHIP

All states in the Union, as well as the District of Columbia, Alaska, Hawaii and Puerto Rico, have made certain adjustments in their licensure legislation or practices, where such were required, to facilitate the licensure of graduates under the accelerated programs, at least for the duration of the war.

The information received from those states whose licensure laws include specific premedical requirements seems to indicate that there should be no licensure difficulties encountered by students whose premedical work was taken under the A. S. T. or the Navy V-12 or comparably accelerated civilian programs.

Of the twenty-three states requiring an internship for licensure, at least for the duration of the war, eight states (and Alaska) will accept a nine month internship as fulfilling the internship requirement. Twelve states (plus the District of Columbia and Puerto Rico) require an additional three months in a civilian hospital or military service and will withhold the license until this is completed but will permit applicants for licensure to write the examination on completion of the nine month internship. In three states physicians are not eligible to take the examination until after completion of a year's internship, three months of which may be in the military

service. Officers seeking licenses in these three states must delay licensure until after the war or seek furloughs to take the examinations. In the past it has been possible for officers to obtain furloughs for this purpose. Four states specifically require the military medical service to be in a military hospital.

FACULTY MEMBERS IN WAR SERVICES

On July 1, 1944 the seventy-seven medical schools and schools of basic medical sciences in the United States had contributed a total of 5,828 of its faculty members to the armed forces. This number is somewhat larger than the 5,637 of last year and is still about 10 per cent of the medical officers in the armed forces. It seems apparent that medical schools have contributed approximately as large a proportion of their faculties to the armed forces as the proportion of physicians not engaged in academic work who have been commissioned.

This depletion of faculties continues to handicap the teaching of more medical students and in less time than in normal years. Further faculty reductions have resulted from increasing participation in war research and special war assignments.

The loyalty and devotion of faculty members remaining to carry on the increased work of the medical schools under adverse conditions is to be highly commended. In the demobilization period special consideration should be given to the preferential early release of physicians on medical school

faculties, to restore the quality of medical instruction to a higher level as soon as possible. Conferences on the possibility of such arrangements have been held with the appropriate authorities.

POSTWAR MEDICAL TRAINING

Under the direction of Lieut. Col. Harold C. Lueth, Liaison Officer of the Surgeon General, a study has been conducted by the Committee on Postwar Medical Service pertaining to the educational plans of medical officers after the war. On the basis of early returns in this study estimates were made by the Committee on Postwar Medical Service and the Council on Medical Education and Hospitals concerning the probable requirements to meet the needs of all the 60,000 medical officers in the armed forces. These estimates were published in *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION*, Nov. 11, 1944, pages 709-711. This material was given wide distribution. Reprints were sent to several thousand individuals, agencies and institutions. Returns have now been received and analyzed from 21,000 medical officers. On the basis of these more complete returns it is likely that some modifications have been made in estimates of the overall demand and the total expansion required in educational facilities. However, the Council on Medical Education and Hospitals proceeded to the necessary task of determining available places in hospitals and other educational institutions to accommodate returning medical officers. To this end, in cooperation with the Committee on Postwar Medical Service, the Council directed a communication to all approved intern and residency hos-

pitals requesting their aid in the development of educational facilities for returning medical officers. Replies have now been received from 256, or approximately 25 per cent, of the 1,054 civilian hospitals approved by the Council for intern and/or residency training. This group has indicated that 1,752 additional residencies can be provided in the various divisions of medicine and surgery. Of this number 1,042 represent expansions of residency services already approved by the Council. From the data secured on the educational requirements of medical officers it has been estimated that about 5,700 additional residencies will be needed if the demobilization extends over a period of two years.

From the data contained in the accompanying table it seems probable that the hospital facilities will be adequate to meet the anticipated demand for postwar graduate training. The estimated requirements in some fields can practically be fulfilled by the group that has already reported. In most of the other specialties the required facilities will no doubt be available when an additional 25 to 50 per cent of the hospitals have replied. The main exception is in the general surgical field, where 263 places have now been reported in relation to the estimated need of 1,595. Few hospitals have supplied information regarding mixed residency training, but it should be noted that all hospitals approved for internships are likewise accredited for general residencies. There should be no considerable difficulty, therefore, in providing the number of general training courses requested by the medical officers.

It is gratifying that hospitals are seriously facing their responsibilities in the postwar educational field and, through committees, are devoting considerable study to possible expansion of educational facilities without a deterioration in the quality of training. Interhospital collaboration in these plans has developed in a number of areas usually centering in a medical school hospital or a large hospital not associated with a medical school but which has a well established program of education for house officers.

In carrying out these objectives the Council has worked closely in collaboration with the Committee on Postwar Medical Service, the Advisory Board for Medical Specialties, the various specialty boards themselves and a number of professional organizations in the country devoted to one or another of the specialty fields.

Although the major task appears to be that of providing hospital facilities for definitive training of men in residency, internship and fellowship fields, progress has also been made in the development of review and refresher courses for men who desire briefer periods of training. This work is being carried out in close collaboration with the Association of American Medical Colleges, to which the Committee on Postwar Medical Service has assigned the major responsibility in this field, since medical schools and their faculties will play an important role in the development of review and refresher courses.

The appointment of veterans to house officerships will be facilitated by a policy in effect under the Procurement and Assignment Service in which veterans need not be counted in house officer quotas at any time.

VETERANS' BENEFITS FOR MEDICAL STUDENTS

The educational section of the "G. I. Bill of Rights" provides that "any person who served in the active military or naval service on or after Sept. 16, 1940 and prior to the termination of the present war and who shall have been discharged . . . and whose education for training was impeded, delayed, interrupted or interfered with by reason of his entrance into the service . . . and who either shall have served ninety days or more . . . shall be eligible for and entitled to receive education or training under this part. . . . Discharged service men under 25 years of age at the time they entered the service are assumed to have had their education impeded or delayed, while those 25 years of age or over at the time they entered the service will be expected to supply evidence that such a delay or obstacle to their education occurred." Three months of military service entitle the veteran to one year of further education; twelve months of

service, two years of education; twenty-four months of service, three years of education.

The bill provides for tuition and fee benefits and subsistence benefits. The tuition and fee benefits are paid to the school for tuition, fees, books, equipment and other expenses but may not exceed \$500 for an ordinary school year. The subsistence benefits paid to the veteran are \$50 per month if there are no dependents, or \$75 per month if the veteran has a dependent or dependents.

The law clearly provides that a veteran eligible for benefits must be fully acceptable to the school he seeks to enter. In medicine, this means that an applicant must meet the civilian medical school admission requirements, including scholastic and other qualifications. This provision is especially important in medicine, since the lives of his patients are in the hands of the physician. Only fully qualified men and women can be trained for such responsibilities. It would serve neither the public nor the veteran for medical schools to admit unqualified ex-service men.

VETERANS' BENEFITS FOR PHYSICIANS DESIRING POSTGRADUATE AND GRADUATE TRAINING

A subcommittee of the Committee on Postwar Medical Service working with the Council has held extensive correspondence and conferences with the Veterans Administration concerning the applicability of the G. I. Bill of Rights to physicians who will seek additional hospital and other advanced training after the war. The Veterans Administration was of the opinion that any physician who is now in any of the branches of the service and has been on active duty for more than ninety days will be eligible for those benefits described in the preceding section.

Even those who are more than 25 years old and desire refresher or other courses will no doubt be considered eligible even though they may have entered the Army at a time when their education might have been assumed as completed, since the law in providing refresher and retraining courses is naturally to be interpreted in a liberal spirit.

The law provides that the administrator shall pay to the educational or training institution the tuition costs and fees that are customarily charged and may also pay for books, supplies and equipment and other necessary expenses, provided the payments with respect to any one person should not exceed \$500 for an ordinary school year. These payments are not to be paid to "establishments furnishing apprentice training on the job." The law provides that, if the institution has no established tuition fee or if the administrator deems the established tuition fee to be inadequate compensation, the administrator is authorized to provide for the payment, again, however, with the \$500 ordinary school year limitation.

Applying these provisions of the law to the case of residencies in our hospitals and courses in our universities for our physician veterans, the Veterans Administration was of the opinion that there would be no difficulty about the payment of tuition and fees by the administrator for those physician veterans who elect clinical courses in university and other acceptable hospitals where a formal educational program has been inaugurated. The administration was also of the opinion however that, provided the hospital can be certified to the administrator by the appropriate state agency as a competent educational and training institution, the administrator may fix the tuition to be paid to such an institution under the provisions of the law. If the hospital is certified as a bona fide educational institution, the tuition for the physician veterans can be paid to that hospital even though the hospital still continues to pay a stipend to the veteran.

CREDIT FOR COURSES TAKEN UNDER MILITARY AUSPICES

The armed services offer men and women on active duty a variety of educational opportunities. Some of the courses offered by such organizations as the United States Armed Forces Institute, Madison 3, Wis., are at the college level and warrant the subsequent awarding of college credit by a civilian institution. A committee of the American Council on Education is preparing "A Guide to the Evaluation of Edu-

cational Experiences in the Armed Services" to assist colleges in determining what academic credit ought to be allowed for such work. In this venture the Council on Medical Education and Hospitals has cooperated with the United States Armed Forces Institute by inclusion of a statement concerning such courses in its booklet "Choice of a Medical School." This booklet advises prospective medical students concerning their professional and preprofessional studies and has a wide circulation. Nearly ten thousand copies of this booklet were provided the Army and the United States Armed Forces Institute for distribution to various agencies and military units throughout the world in assisting men in the armed forces to conduct some of their premedical studies before discharge. The Council on Medical Education and Hospitals will accept the premedical credit allowed a student by an approved college which follows the recommendations of the guide previously mentioned and prepared by the American Council on Education.

LATIN AMERICAN PHYSICIANS

The Council is deeply interested in the development of educational opportunities for Latin American physicians, who are coming to this country in increasing numbers for graduate training. The decline of learning and science, including medical education, in Europe during the war will tend to increase the importance of the United States as a center for advanced training for years to come. Thus we may expect a continual increase in the number of Latin American physicians who will be seeking further training in the schools and hospitals of the United States. This tendency deserves the full support of the medical profession in this country, which will share in a mutually beneficial exchange of ideas and the cementing of lasting inter-American friendship.

A study is now being made by the Council to determine the number of Latin American physicians currently in training in the United States, the type of training involved and the extent to which educational facilities in hospitals may need to be expanded to meet possible future needs. Qualified medical graduates of Latin American schools may from the Council's point of view serve as interns and resident physicians in approved hospitals. To assist such applicants in obtaining suitable appointments, lists of available internships and residencies will be prepared and will also be furnished to the various agencies that are interested in the training of medical personnel from the other American republics. The Council has already established contacts with the following Washington agencies: the Institute of International Education, the Division of Science, Education and Art of the State Department, the Office of the Coordinator of Inter-American Affairs, the Institute of Inter-American Affairs and Pan American Sanitary Bureau.

The directing board of the Procurement and Assignment Service has announced that graduates of Latin American schools will not be counted in hospital quotas at least for the first nine months. This ruling should do much to facilitate the appointment of Latin American physicians and thus help to establish a wider scope of hospital training for them in the United States.

It is recognized that Pan American problems in medicine go beyond those of medical education even though this may be the most important aspect of the problem at the present time. Therefore it might be desirable to establish a committee of the American Medical Association to deal with the overall problem, which will become of increasing importance after the war. Such a committee will lend considerable prestige to such activities as the Council might undertake.

GRADUATE CONTINUATION COURSES FOR PRACTICING PHYSICIANS

The necessity for continuation courses of study in the medical specialties has never been more urgent than at the present time. Physicians in civilian practice have been compelled to enlarge their field of activity and to refresh their knowledge of the intricacies of modern diagnosis and treatment. Physicians in military service and returning medical officers are also encountering problems. The demand for all means of instruc-

tion is greater than it has ever been. Medical educators and interested organizations and institutions throughout the country are attempting to assist physicians called on to assume new responsibilities by offering refresher courses or continuation courses and by the presentation of scientific papers or lectures on timely subjects. These individuals, who will give or have given so generously of their time to participate in the instructional programs, constitute a large and distinguished faculty of medicine.

The Council on Medical Education and Hospitals publishes semiannually advance information concerning postgraduate continuation courses for practicing physicians. These include courses in a wide variety of fields in clinical medicine and the basic sciences. The courses are for variable periods from a few days to several months. Some are concentrated full time courses and others are part time. In *THE JOURNAL* for Dec. 23, 1944 there were listed 354 such courses available during the first half of the current year. The opportunities listed are offered by hospitals, medical schools, graduate medical schools or other agencies in twenty-one states and include thirty-nine specialty or subspecialty subjects.

HILL-BURTON BILL

Senate Bill 191, introduced on Jan. 10, 1945 by Senator Lister Hill of Alabama for himself and Senator Harold Burton of Ohio, provides for an amendment of the Public Health Service Act to authorize grants to states for surveying their hospital facilities and for planning and constructing additional hospitals and health centers. The Secretary was designated to appear before the Senate Committee on Education and Labor, to which this bill was referred, to indicate to the committee that the Board of Trustees of the American Medical Association had agreed to the general policies of the Hill-Burton bill, since its provisions appear to be within the platform of the American Medical Association. In these hearings the Secretary expressed gratification with the scientific approach manifested in this bill. The manner in which the existing faulty distribution of hospitals is to be assessed conforms to the best scientific procedures.

The proposed surveys, conducted by state agencies, with the assistance of all groups concerned with hospital care, should provide the information requisite for an intelligent program of hospital construction in areas deficient in hospital facilities.

The sound approach to a solution of the problems of better distribution of medical care and hospital facilities on the part of the Committee on Education and Labor is reflected not only in the provisions of this bill but in the approach to these problems by the Subcommittee on Wartime Health and Education, under the chairmanship of Senator Claude Pepper. The interim report of this committee, published in January 1945, is an admirable document, containing invaluable information for the formulation of programs for improved medical care.

Certain of the procedures suggested in this report and in the hospital construction bill are practically identical and equally sound. The report recommends that "state programs should be drawn up by state health planning commission" and "before federal funds could be granted, however, overall state plans and individual projects should be reviewed and approved by the United States Public Health Service to make sure that they meet certain standards of construction, operation and complete, coordinated service." Equally significant is the recommendation that "grants to both public and voluntary institutions included in the plan would be administered through a state agency."

MEDICAL SCHOOLS VISITED DURING THE CALENDAR YEAR 1944

The following medical schools were visited by the Secretary for formal inspection, advice and consultation or other purposes during the calendar year 1944.

University of Arkansas School of Medicine (twice).
University of California Medical School.
College of Medical Evangelists.
University of Southern California School of Medicine.
Stanford University School of Medicine.
University of Colorado School of Medicine.

FORMAL ACTIONS ON MEDICAL SCHOOLS DURING THE CALENDAR YEAR 1944

During the calendar year 1944, following a detailed inspection by the Secretary, the Council took action on the status of three medical schools. The Southwestern Medical College of the Southwestern Medical Foundation, Dallas, Texas, was approved. The University of Utah School of Medicine, which had formerly operated a school of the basic sciences, has had the full four year medical curriculum in operation for about two years. This school was approved as a four year medical school on June 11, 1944. The first class graduated in September 1944. The University of Arkansas School of Medicine, which had been on probation, was removed from this status and restored to full accreditation.

NEW MEDICAL SCHOOLS

The University of Alabama has virtually completed arrangements whereby a third year class will commence its work in the autumn of 1945. This school, formerly an approved institution of the basic medical sciences, employs the facilities of the Hillman and Jefferson hospitals in Birmingham for clinical instruction. The project appears to be under competent leadership and seems to have arranged for adequate clinical facilities.

The University of Missouri now conducts an approved school of the basic medical sciences at Columbia, Mo. It is proposed that this institution be expanded to a full four year medical school, but there is difference of opinion as to whether the new institution should be located in Columbia, Mo., where the university is located, or in Kansas City, where extensive hospital facilities exist.

The University of North Carolina has participated in a statewide plan for the improvement of medical care, and it has been recommended that the University of North Carolina be expanded to the four year status from its present designation as an approved school of the basic medical sciences. It is suggested that a state hospital be constructed in Chapel Hill, where the entire medical school would be located.

In North Dakota and in South Dakota and Mississippi proposals have also been made for expansion from the two year to the four year status.

This tendency on the part of the schools of basic medical sciences to expand into four year medical schools can be attributed primarily to three factors: first, it is becoming increasingly difficult for those who complete the work of the basic medical sciences to gain acceptances to the junior classes of approved four year institutions; secondly, it is generally recognized that modern instruction in the basic medical sciences is handicapped unless clinical facilities are available. This applies primarily to work in pathology but bears on the work of other departments as well and is particularly the case in the teaching of physical diagnosis, which should be completed by the time a student enters the junior year of the medical school. Third, it is the belief in some instances that provisions for the complete training of a medical student within the bounds of a given state will stimulate graduates to remain in that state to practice medicine and therefore relieve the shortage of physicians in needy areas. This tendency toward the expansion of the two year institutions has been encouraged by the Council on Medical Education and Hospitals in instances in which it is apparent that facilities for such development are available. In other instances it is highly questionable whether adequate facilities and funds are available. In such cases the schools of basic medical sciences would serve best by strengthening the programs they now conduct rather than attempt a poorly conceived expansion to a medical school offering the full four year course of instruction at a mediocre or poor level.

INSPECTION OF HOSPITALS, TECHNICAL SCHOOLS
AND SPAS, 1944

In the accompanying table are summarized the inspections of hospitals, technical schools and spas made by the Council during the calendar year 1944.

Inspections of Hospitals, Technical Schools and Spas

Hospitals	
Intern training	26
Residency and fellowships	61
Intern training and residencies	13
Registration	15
Total	115
Individual residencies and fellowships investigated	151
Technical Schools	
Clinical laboratory schools	15
Physical therapy schools	4
Occupational therapy schools	5
Medical record librarian schools	2
Total	26
Spas	1
Total number of days in the field	171

CENSUS OF HOSPITALS

The twenty-fourth annual hospital report of the Council was published in the Hospital Number of THE JOURNAL, March 31, 1945. This survey included 6,611 registered hospitals as compared with 6,655 in 1943. The reduction in the number of hospitals, however, was not accompanied by a correspond-

ing loss in bed capacity; on the contrary, the construction of additional units and the expansion of existing services resulted in a net gain of 80,691 beds, the equivalent of a new 220 bed hospital for each day of the year. The present capacity of the registered hospitals is 1,729,945 beds, including 1,352,278

in governmental hospitals and 377,667 in the nongovernmental institutions. Again the principal gain was in the federal group, which now has 551,135 beds, or 74,462 more than were reported in 1943.

The most striking feature of the Council's report is the continued expansion of inpatient hospital care, as evidenced by the unprecedented total of 16,036,848 admissions in 1944, an increase of 662,150 in relation to the previous survey. In this connection it may be noted that the nongovernmental hospitals, which have only 22 per cent of the beds, received 59.2 per cent of the total admissions. The general hospitals had 15,060,403 admissions, or 93.9 per cent of all patients admitted to the registered hospitals last year. The tremendous volume of hospital service is also indicated in the average daily census of 1,299,474, which represents a total of 475,607,484 patient days in the twelve months period under consideration. In addition to the number of patients treated, the registered hospitals gave care to 1,919,976 newborn infants. When compared with the previous report, the number of births show a reduction of 4,615, whereas increases of 265,659 and 253,992 occurred in 1942 and 1943 respectively.

A special study of hospital facilities for children showed that 61,262 beds are regularly available for this purpose exclusive of bassinets for newborn infants. The general hospitals have the greatest number of children's beds, a total of 36,462. Reports were also included regarding internships and residencies, schools of nursing education and nursing and technical personnel. At present 718 civilian hospitals are approved for intern training and 692 for residencies in specialties. These include 337 hospitals which offer acceptable training in both classifications. Accredited schools of nursing education are now conducted in 1,439 hospitals with a total enrolment of 129,879 students including Cadet Nurses. In 1943 the number of student nurses was 110,222.

RECOMMENDED CHANGE IN THE ESSENTIALS
OF AN ACCEPTABLE MEDICAL SCHOOL

The Council on Medical Education and Hospitals recommends that the chemistry requirement listed in the Essentials of an Acceptable Medical School, page 4, under VII, "Requirements for Admission" (to a medical school) be changed from the present wording, which reads "general and inorganic chemistry," to read "inorganic and organic chemistry." Practically all medical schools require training in organic chemistry, which is essential for the proper mastery of the medical school material, particularly in the field of biochemistry.

RECOMMENDED CHANGE IN ESSENTIALS OF AN
ACCEPTABLE SCHOOL FOR PHYSICAL
THERAPY TECHNICIANS

The Council recommends to the House of Delegates that the Essentials of an Acceptable School for Physical Therapy Technicians be changed by the addition of the sentence "Technicians are trained in these schools to work under the direction of qualified physicians and not as independent practitioners of physical therapy." This statement should be added after item 1 under section I. "Organization." A statement similar to this now appears in the essentials for schools for clinical laboratory technicians, x-ray technicians and occupational therapists.

RECOMMENDED REVISION OF THE ESSENTIALS OF
AN ACCEPTABLE SCHOOL FOR MEDICAL
RECORD LIBRARIANS

The Council recommends to the House of Delegates that the Essentials of an Acceptable School for Medical Record Librarians be changed substituting the following for the material now included under "V. Curriculum":

V. CURRICULUM

1. The course of training should include not less than fifty weeks of theoretical instruction and practical hospital experience.

2. Theoretical instruction may be presented by informal conferences or formal lectures and should include the following:

	Recommended Time (Clock Hours)
Anatomy and physiology.....	100
Fundamentals of medical science.....	30
Bacteriology, doctors' lectures in all medical specialties	
Medical terminology	30
Etymology	
Abbreviations	
Drug terms	
Nomenclatures—disease, operative, symptomatology	
Medical record library science.....	100
History	
Medicolegal	
Ethics	
Securing and preserving	
Statistics	
Indexes	
Management	10
Hospital organization	
Interdepartmental relations	
Purchase of supplies, etc.	
Supervision, function and techniques	
Psychology (recommended if not specified for admission)	(25)
Total clock hours.....	270

3. Practical training should involve all activities associated with the care of medical records. This should include:

Orientation
Filing
Outpatient department and social service
Admission and discharge routine, including hospital statistics
Adjunct department records
Secretarial practice
Medicolegal relationships
Indexes, including comparative and group studies
Admitting office
Patient census
Medical library
Department management

Sufficient time should be devoted to each assignment so that students may become familiar with all functions of the medical record library and the various departments of the hospital. Additional experience in the handling of records in the pathology and radiology departments is recommended. To augment the training program, field trips should be arranged when possible to visit other hospitals and study their record library equipment and methods.

These changes are in accordance with policies and curriculums now in operation in the approved schools for medical record librarians. They were developed in collaboration with representatives of the American Association of Medical Record Librarians and have the approval of that organization.

NURSING

In June 1944 the House of Delegates passed the following resolution:

WHEREAS, There is a very obvious deficiency in trained personnel for nursing; and

WHEREAS, The demands for adequate nursing are apt to be greater; be it

Resolved, That the Council on Medical Education and Hospitals communicate with the various national organizations concerned with nursing for the purpose of discussing the present nursing situation in order that proper nursing bodies may consider the matter with a view toward its amelioration.

Pursuant to this direction by the House of Delegates, the Council has appointed Dr. F. H. Arestad as a representative on the National Nursing Council for War Service. In addition, the Secretary is a member of the Special Committee on Accrediting of the National League of Nursing Education. Also Dr. Herman G. Weiskotten is a member of the National Organization of Public Health Nursing and Dr. Charles Gordon Heyd has been representing the Council on the National Association of Practical Nurse Education. Nursing problems of wartime have been under frequent consideration by these bodies, with which the Council keeps in close touch. The Council has collaborated with the National Nursing Council for War Service in the collection of extensive data concerning nursing personnel in various categories in the registered hos-

pitals of the country. This material was published in the 1945 Hospital Number of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION (March 31, 1945).

BOARD OF GENERAL PRACTICE

The resolution presented to the House of Delegates in June 1944 calling for the establishment of a board of general practice reads as follows:

Resolved, That there shall be and is hereby constituted a Board of General Practice of the general practice sessions of the Association, which shall consist of seven members of the American Medical Association, all of whom shall be qualified and recognized general practitioners; that said Board of General Practice shall be duly organized as a corporate body; and be it further

Resolved, That said Board of General Practice shall be and is vested with all powers necessary for the regulation, control, supervision and gradation of the general practice sessions.

The House of Delegates referred this resolution to the Council on Medical Education and Hospitals for transmission to the Advisory Board for Medical Specialties. On transmittal of this resolution to the Advisory Board for Medical Specialties it was stated that consideration of this resolution by the Advisory Board would depend on the formulation of more concrete objectives to be presented in writing to the Advisory Board for Medical Specialties by an organized group representing the proposed board. As yet such objectives have not been presented to the Advisory Board for Medical Specialties or its Committee on Standards and Examinations.

TEACHING OF PHARMACOLOGY

At the June 1944 meeting of the House of Delegates the Reference Committee on Reports of Officers stated that it "desires to endorse his [President-Elect Kretschmer's] suggestion that the Council on Medical Education and Hospitals give further consideration to improvements in the teaching of pharmacology in medical schools, particularly as this applies to prescription writing and drug therapy." In accordance with these directions, discussions have been held with Dr. Austin E. Smith, Secretary of the Council on Pharmacy and Chemistry, who has completed an extensive study of the requirements for adequate instruction in pharmacology, including prescription writing and drug therapy. The results of this study by Dr. Smith are being presented for publication in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION. To assist in carrying out its instructions, the Council will distribute reprints of this paper to the medical schools.

INSTRUCTION IN MEDICAL SOCIOLOGY, MEDICAL ECONOMICS AND MEDICAL ETHICS

The Council on Medical Education and Hospitals was requested by the Council on Medical Service and Public Relations and directed by the House of Delegates at the June 1944 meeting, as a result of the report of the Reference Committee on Legislation and Public Relations, to stimulate the development in medical schools of courses in medical sociology, medical economics and medical ethics. Pursuant to these directions a study was made of the extent to which such work is now offered in approved medical schools. Of the seventy-seven approved medical schools and schools of the basic medical sciences in the United States, forty-two now offer some work in this field. It is apparent that there is considerable lack of uniformity and great differences in the amount of time devoted to these subjects in these schools. In some instances material in this field is offered in conjunction with other courses. It is suggested that the Council on Medical Service and Public Relations give thought to the preparation of an outline for a course in this field giving the subject matter which ought to be covered and possible source materials for instructors as well as students in such a course. In a number of instances a lack of information and of organized sources of material have militated against the presentation of adequate work in this field.

COUNCIL PUBLICATIONS

Major publications during 1944 and thus far in the present year include:

Hospital Service in the United States.
State Board Number of THE JOURNAL.
Medical Education in the United States and Canada.

Compilation of Special Reprint Edition of Papers prepared for the 1945 Annual Congress on Medical Education and Licensure.
Choice of a Medical School.
Postwar Graduate Medical Education.
Approved Colleges of Arts and Sciences.
Schools for Clinical Laboratory Technicians.
Schools for Physical Therapy Technicians.
Schools of Occupational Therapy.
Schools for Medical Record Librarians.
Schools for X-Ray Technicians.

COLLABORATION WITH OTHER AGENCIES

The Council continues to collaborate closely with several agencies, including (1) the Association of American Medical Colleges in all matters pertaining to medical schools, (2) the various American specialty boards in matters relating to the approval of residencies, (3) the Advisory Board for Medical Specialties, with which the Council held a joint meeting in February 1945, (4) the American Council on Education in problems associated with legislation providing postwar education for veterans and plans for college accreditation of academic work done by soldiers and sailors in various military educational programs, (5) the American College of Surgeons, (6) the American Hospital Association, (7) the Committee on Postwar Medical Service, (8) the Federation of State Medical Boards of the United States, (9) the Armed Forces Institute, (10) the Institute of International Education, (11) the Office of the Coordinator of Inter-American Affairs, (12) the State Department, (13) the Pan American Sanitary Bureau, (14) the American Dental Association, (15) the National Nursing Council for War Service, (16) the National League of Nursing Education, (17) the National Organization of Public Health Nursing, (18) the National Association of Practical Nurse Education and (19) the Joint Orthopedic Nursing Advisory Service.

Government agencies with which there have been frequent conferences and close cooperation have included the offices of the Surgeons General of the Army and Navy and Public Health Service, the Army Specialized Training and Navy V-12 officials, the Procurement and Assignment Service, the Social Security Board, the War Production Board and the Office of Vocational Rehabilitation.

APPRECIATION

In the course of its work involving contacts with government and military officials as well as officers and officials of medical schools, hospitals, licensing boards and technical schools the Council has met with the utmost in cooperation at every hand. It is particularly gratifying to note the willingness with which all concerned cooperate with members of the Council and its staff in efforts to maintain adequate educational standards in these difficult times. The readiness in supplying data for the special numbers of *THE JOURNAL* is deeply appreciated. Such information finds wide usage by government bodies, hospitals, medical schools, medical students and physicians. The Council especially desires to express its appreciation to the general officers, the trustees and the members of the House of Delegates of the American Medical Association for the wholehearted manner in which they have cooperated with the Council and assisted it in every activity of the past year.

Respectfully submitted,

RAY LYMAN WILBUR, Chairman.
H. G. WEISKOTTEN.
J. H. MUSSER.
HARVEY B. STONE.
REGINALD FITZ.
RUSSELL L. HADEN.
CHARLES GORDON HEYD.
VICTOR JOHNSON, Secretary.

Committee on American Health Resorts

The Committee on American Health Resorts respectfully submits the following report for the year 1944:

The Committee on American Health Resorts functioned in 1944 under considerable difficulties. Of the normal membership of five, one place was vacant and Lieut. Col. Euclid M. Smith was occupied with military duties.

The principal accomplishment of the Committee during 1944 was the publication of papers on physical therapy and spas under the following titles:

"Nature of Natural Facilities Used at Health Resorts," by W. S. McClellan and Charles I. Singer.
"The Types of Treatments Administered at Health Resorts," by M. B. Jarman.
"The Economic Aspects of Health Resort Therapy," by A. M. Simons.
"Underwater Therapy at Spas," by Euclid Smith and Billie Crook.
"The Place of Health Resort Therapy in the Treatment of Conditions Affecting the Nervous System," by George B. Fletcher.
"The Place of Health Resort Therapy in Rehabilitation Following Traumatic and Other Injuries," by Frank Krusen.
"Thalassotherapy," by Charles I. Singer and Kenneth Phillips.

The first seven articles prepared under the auspices of the Committee were published in 1943.

There was no meeting of the Committee on American Health Resorts in 1944, but a meeting was held early in 1945.

(To be continued)

Medical Legislation

MEDICAL BILLS IN CONGRESS

Scientific Research

Joint hearings have been scheduled by the Senate Committees on Commerce and Military Affairs on three bills relating to the formulation of a federal program for scientific research, S. 1297, S. 1248 and S. 1285. The hearings will begin on October 8 and will extend, it is anticipated, for a period of from three to four weeks. It is understood that the following witnesses have been invited to testify: Dr. Isaiah Bowman, president of Johns Hopkins, Dr. James B. Conant, president of Harvard, Secretary of War Patterson, Secretary of the Navy Forrestal, Secretary of Commerce Wallace, Secretary of the Interior Ickes, Dr. Vannevar Bush, Director of the Office of Scientific Research and Development, Harold Smith, Director of the Budget, Eric Johnston, president of the United States Chamber of Commerce, Ira Mosher, president of the National Association of Manufacturers, Phillip Murray, president of C. I. O., and William Green, president of A. F. of L.

Army Medical Corps

Senator Langer, North Dakota, has introduced S. J. Res. 97, to provide for replacement of medical personnel commissioned from civilian life with persons trained under the Army specialized training program. This bill proposes that, in order to accelerate the return to civilian life of physicians, dentists and veterinarians who have served in the Army during the war, the services of personnel trained under the Army specialized training program should be utilized to the greatest extent practicable to replace such physicians, dentists and veterinarians.

A bill introduced by Representative Traynor, Delaware, H. R. 4147, proposes to establish a Chiropody Corps in the Medical Corps of the Army and to provide for a Chiropody Reserve Corps. It is pending before the House Committee on Military Affairs.

Navy Nurse Training School

A bill introduced by Representative Price, Florida, proposes to establish a United States Navy Training School for Nurses. The trainees will be selected on the same terms and conditions as midshipmen are selected and admitted to the United States Naval Academy. On graduation, trainees will be commissioned as ensigns in the Navy Nurse Corps and may be assigned to duty with the Navy or to duty in hospitals under the jurisdiction of the Veterans Administration.

Miscellaneous

A bill introduced by Representative Larcade, Louisiana, H. R. 4132, provides for the discharge or release from active duty of those members of the armed forces desiring to resume their education or training.

A reorganization of the agencies of the government is contemplated by a bill introduced by Representative Manasco, Alabama, H. R. 4129. This bill has been favorably reported by the House Committee on Expenditures in the Executive Departments.

The Vannevar Bush Report

This analysis was presented to the Committee on Postwar Medical Service on September 23 by a subcommittee of the Committee on Postwar Medical Service appointed by that body to study the Bush report and make recommendations to the entire committee.

1. THE VANNEVAR BUSH REPORT

The Bush report was made in response to a request by President Roosevelt for advice concerning the desirability of federal financial support of research. The report was made by Dr. Bush in collaboration with a number of leaders in science who were organized into four separate committees: (1) Medical Advisory Committee, Dr. W. W. Palmer chairman, (2) Committee on Science and the Public Welfare, Dr. Isaiah Bowman chairman, (3) Committee on Discovery and Development of Scientific Talent, Dr. Henry Allan Moe chairman, and (4) Committee on Publication of Scientific Information, Dr. Irvin Stewart chairman. Dr. Bush said "Although the report which I submit herewith is my own, the facts, conclusions and recommendations are based on the findings of the committees."

The report can be considered under two main headings: (1) a development of the main reasons for federal support of research and (2) a specific plan of implementation in the organization of a National Research Foundation as a separate agency of the executive branch of the federal government.

2. REASON ADVANCED IN THE REPORT FOR FEDERAL SUPPORT OF RESEARCH

The most compelling argument cited in the report for a continuation of federal support of research is the success with which the wartime research of the Office of Scientific Research and Development was conducted in the medical and physical sciences for purposes of national defense. These achievements are claimed to warrant federal support for the extension of research.

The report maintains that, in the main, such work can best be done in our universities, colleges and research institutes under their own organization and administration. Federal support can in many important ways enable these institutions to intensify their research programs with the expectation of even greater success than at present, particularly in view of the mounting costs of research and the limited funds for such purposes in many of these institutions.

Another argument for federal support advanced in the report is the necessity of insuring a continuous availability of research workers now and in the future. This aim can be furthered through the provision of scholarships and fellowships for men and women of promise at the undergraduate and graduate levels.

Your subcommittee accepts the force of these arguments and agrees with the conclusions, subject to appropriate safeguards. The subcommittee on the Vannevar Bush report to the President favors federal support of research: it is of the opinion that the support of scientific research by the federal government presents a challenging and compelling opportunity for government to foster the public welfare by assisting in the support of scientific research. To be most effective, this support should leave the policy, personnel and method and scope of research to the colleges, universities and research institutions themselves. Institutional and personal liberty in research should be fully safeguarded. The responsibility for such safeguards should be entrusted to men of scientific achievement, knowledge and leadership.

3. IMPLEMENTATION: RECOMMENDATION OF THE REPORT FOR LEGISLATION

The Bush report recommends that a separate agency be established, to be known as the National Research Foundation; it should consist of nine "members" selected by the President, who should be persons "not otherwise connected with the government and not representative of any special interest." The report strongly urges that the members be given complete freedom in

the organization and operation of the foundation. The members would elect their own chairman annually. They also would appoint a director as chief executive officer of the foundation and the chairman and five members of each of the five following proposed divisions, after requesting and considering "recommendations from the National Academy of Sciences, which should be asked to establish a new National Research Foundation nominating committee in order to bring together the recommendations of scientists in all organizations."

The five divisions are (1) Division of Medical Research, (2) Division of Natural Sciences, (3) Division of National Defense (which also includes Army and Navy representation), (4) Division of Scientific Personnel and Education and (5) Division of Publications and Scientific Collaboration.

The foundation would make grants to educational and research institutions for support of scientific research on recommendation of the divisions. It is proposed that these funds be made available not only to institutions of "a demonstrated research capacity" but also to those where "latent talent or creative atmosphere affords promise of research success."

Dr. Bush gives the following "Five Fundamentals" which must underlie such a government program:

1. Whatever the extent of support may be, there must be stability of funds over a period of years, so that long range programs may be undertaken.

2. The agency to administer such funds should be composed of citizens selected only on the basis of their interest in and capacity to promote the work of the agency. They should be persons of broad interest in and understanding of the peculiarities of scientific research and education.

3. The agency should promote research through contracts or grants to organizations outside the federal government. It should not operate any laboratories of its own.

4. Support of basic research in the public and private colleges, universities and research institutes must leave the internal control of policy, personnel and the method and scope of the research to the institutions themselves. This is of the utmost importance.

5. While assuring complete independence and freedom for the nature, scope and methodology of research carried on in the institutions receiving public funds, and while retaining discretion in the allocation of funds among such institutions, the foundation proposed herein must be responsible to the President and the Congress. Only through such responsibility can we maintain the proper relationship between science and other aspects of a democratic system. The usual controls of audits, reports, budgeting and the like should, of course, apply to the administrative and fiscal operations of the foundation, subject however to such adjustments in procedure as are necessary to meet the special requirements of research.

Basic research is a long term process—it ceases to be basic if immediate results are expected on short term support. Methods should therefore be found which will permit the agency to make commitments of funds from current appropriations for programs of five years' duration or longer. Continuity and stability of the program and its support may be expected (a) from the growing realization by the Congress of the benefits to the public from scientific research and (b) from the conviction which will grow among those who conduct research under the auspices of the agency that good quality work will be followed by continuing support.

Research now being conducted in existing government agencies is to remain under their auspices, with the foundation serving in a consultative, advisory and correlating capacity.

The scholarship program involves 6,000 four year undergraduate scholarships to promising high school graduates (21,000 at any one time, after the program is in full operation) and 300 three year graduate scholarships (900 at any one time, after a while) at an annual cost of \$30,000,000. It also makes provision for fellowships for advanced training in fundamental research. Recipients of these scholarships and fellowships are to be enrolled in a National Science Service, subject to call by the government "in time of war or other national emergency declared by Congress or proclaimed by the President."

Regarding patents, the report states:

The public interest will normally be adequately protected if the government receives a royalty-free license for governmental purposes under any patents resulting from work financed by the foundation. There should be no obligation on the research institution to patent discoveries made as a result of support from the foundation. There should certainly not be any absolute requirement that all rights in such discoveries be assigned to the government, but it should be left to the discretion of the director and the interested division whether in special cases the public interest requires such an assignment. Legislation on this point should leave to the members of the foundation discretion as to its patent policy in order that patent arrangements may be adjusted as circumstances and the public interest require.

The proposed budget of the foundation is \$33.5 million in the first year, to reach \$122.5 million in five years, allocated as follows:

Activity	Millions of Dollars	
	First Year	Fifth Year
Division of Medical Research.....	5.0	20.0
Division of Natural Sciences.....	10.0	50.0
Division of National Defense.....	10.0	20.0
Division of Scientific Personnel and Education....	7.0	20.0
Division of Publications and Scientific Collaboration.....	0.5	1.0
Administration.....	1.0	2.5
	33.5	122.5

4. SUGGESTIONS OF THE SUBCOMMITTEE

Your subcommittee approves in general the recommendations of the Bush report with respect to implementation subject to the following suggestions:

(a) In the opinion of the subcommittee it would be appropriate if the National Academy of Sciences could advise with respect to the selection of the members of the foundation in the manner recommended in the report for the appointment of members constituting the divisions.

(b) The interests of the five divisions should be adequately represented in the membership of the foundation.

(c) While the divisions should be administratively independent, provision should be made for free interchange of information and discussion.

(d) The five fundamental principles stated in the report would appear to be essential for the effective functioning of the foundation.

(e) The subcommittee questions the advisability or necessity of organizing the "National Science Service" to secure the services to the government in time of emergency of the recipients of the foundation's scholarships or fellowships.

(f) The proportion of funds suggested as an allotment to medical research would seem to be a fair initial estimate but should be considered subject to modification in the light of experience.

(g) Even though there should be federal support of research, it is necessary to preserve the support of research by private foundations and other donors; tremendous advances in science have been made in the past from such support, and it should continue undiminished in the future.

(h) The subcommittee considers the problem of the federal support of the social sciences to be outside the scope of its deliberations.

(i) The subcommittee wishes to reiterate the necessity for complete freedom of the foundation members to allot funds and for the participating institutions to exercise complete freedom in carrying out the research for which they receive support.

(j) In the opinion of the subcommittee, the Magnuson bill (S. 1285) more nearly meets the provision of the Bush report in safeguarding institutional and individual liberty in research than do other pending bills.

5. CONCLUSION

The subcommittee recommends (1) that the Bush report, subject to the qualifications set forth, receive the strong support of the Committee on Postwar Medical Service, (2) that the various agencies represented in the Committee on Postwar Medical Service give consideration to the contents of the subcommittee's report in their public pronouncements and in congressional hearings in which they might be invited to participate and (3) that consideration of proposals and legislation for new federal programs to assist in medical research within restricted areas or specialties of medicine should be delayed until the establishment of some such comprehensive program as that proposed in the Bush report covering all the fields of medicine and natural sciences.

Submitted by Francis G. Blake, Chairman, Frederick A. Collier, Victor Johnson, W. W. Palmer and Alphonse M. Schwittalla.

Committee on Scientific Exhibit

MOTION PICTURES FOR CADET NURSES

The U. S. Office of Education, with the cooperation of the Nurse Education Division of the U. S. Public Health Service, has completed thirteen motion pictures to aid in the training of cadet nurses. The films are all 16 mm., sound. They are accompanied by filmstrips for review, discussion and study, together with an instructor's manual.

The films may be purchased from visual education dealers or from Castle Films, 30 Rockefeller Plaza, New York 20.

- OE 403. *Bathing the Patient (Home Care)*. 24 minutes.
- OE 404. *Feeding the Patient*. 15 minutes.
- OE 406. *The Vital Signs and Their Interrelation—Body Temperature, Pulse, Respiration, Blood Pressure*. 32 minutes.
- OE 408. *Therapeutic Use of Heat and Cold: Part I. Administering Hot Applications*. 21 minutes.
- OE 409. *Therapeutic Uses of Heat and Cold: Part II. Administering Cold Applications*. 22 minutes.

- OE 417. *Care of the Patient with Diabetes Mellitus (Uncomplicated)*. 29 minutes.
- OE 418. *Care of the Patient with Diabetes Mellitus (Complicated)*. 29 minutes.
- OE 419. *Care of the Cardiac Patient*. 33 minutes.
- OE 422. *Teaching Crutch Walking*. 13 minutes.

BRITISH MEDICAL MOTION PICTURES

The British Information Services has made available in the United States several motion pictures. They are all 16 mm., sound. Copies may be rented or purchased from the various offices of the British Information Services or from the British Consular Offices. Information may be obtained from the Film Officer, British Information Services, 360 North Michigan Avenue, Chicago 1.

The following films deal with rehabilitation:

- Psychiatry in Action*. 7 reels, 62 minutes.
Deals with war neuroses, showing special treatments, including physical rehabilitation and occupational therapy.
- Back to Normal*. 2 reels, 16 minutes.
Deals with the fitting and use of artificial limbs.
- Accident Service*. 4 reels, 40 minutes.
Shows the general principles of industrial rehabilitation.
- Hospital Schools*. 1 reel, 11 minutes.
Depicts rehabilitation of children, combined with elementary and high school education.
- Life Begins Again*. 2 reels, 21 minutes.
Shows the rehabilitation of men injured in industry as well as in war.
- Plastic Surgery in Wartime*. 3 reels, 27 minutes.
Gives a generalized, nontechnical view of what can be expected of plastic surgery.

Other motion pictures include medical subjects of interest to both the physician and the layman. Following are some of the subjects:

- Surgery in Chest Diseases*. 4 reels, 43 minutes.
A specialized film for the physician, illustrating the treatment of chest diseases.
- Scabies*. 4 reels, 37 minutes.
Shows the cause and treatment of "the itch."
- Blood Transfusion*. 4 reels, 39 minutes.
Survey of blood transfusion, its development in international medical history and its wartime techniques.
- Out of the Night*. 1 reel, 11 minutes.
Describes the education of the blind in England.
- Men in Danger*. 2 reels, 19 minutes.
A prewar film dealing with industrial accidents and some of the major occupational diseases.
- Rat Destruction*. 1 reel, 10 minutes.
Shows how to deal with the menace of urban rats.
- No Accidents*. 1 reel, 10 minutes.
Emphasizes the importance of routine observance of safety precautions in factories.

Bureau of Information

SUMMARY SHEETS FROM GEORGIA AND MAINE

Completed county summary sheets have been received from counties in Georgia through Dr. E. D. Shanks, secretary, Medical Association of Georgia, and from Maine through Dr. Frederick H. Carter, secretary, Maine Medical Association.

The accompanying tables give data from selected counties in these states. The column giving the number of persons per telephone is used as one index of the economic status of the area.

Georgia

County ¹	Principal Cities ²	Population	Physicians Under 65	Persons per Physician	Persons per Telephone ³
Appling.....	Boxley.....	12,706	4	3,176	59

1. Bureau of Census, estimated population 1943.

2. Bureau of Census, population 1940.

3. Based on 1940 figures, American Telephone and Telegraph Company.

Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratios, however, as the future needs of the communities will be largely dependent on younger physicians.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Committee on American Health Resorts

BAKER HOTEL, MINERAL WELLS, TEXAS, ACCEPTABLE FOR LISTING

The Committee on American Health Resorts has authorized publication of the following statement on the acceptance of the Baker Hotel, Mineral Wells, Texas. A copy of the rules on which the Committee bases its action will be sent on request.

W. W. BAUER, M.D.

The Baker Hotel, Mineral Wells, Texas, applied for listing by the Committee on American Health Resorts of the American Medical Association. The Committee has been furnished with all the information required under its rules, including copies of advertising and promotional material, and a report on an inspection by a Committee representative. The submitted information and the report indicate that the institution is operated in accordance with the rules of the Committee. Minor adjustments in policies of the hotel necessary to insure compliance with the rules have been made.

The Committee on American Health Resorts is satisfied that Baker Hotel is being operated in accordance with the rules of the Committee and has placed this institution on the list of American Health Resorts complying with the Committee rules, for a period of one year beginning Sept. 1, 1945. This listing may be continued for three year periods if the listed institution continues to comply with the rules.

Coming Medical Meetings

American Medical Association House of Delegates, Chicago, Dec. 3-6. Dr. Olin West, 535 N. Dearborn St., Chicago 10, Secretary.

American Ophthalmological Society, Hot Springs, Va., Nov. 12-14. Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

American Society of Tropical Medicine, Cincinnati, Nov. 12-15. Dr. Joseph S. D'Antoni, Tulane Ave., New Orleans 13, Secretary.

Association of American Medical Colleges, Pittsburgh, Oct. 29-31. Dr. Fred C. Zappfe, 5 S. Wabash Ave., Chicago, Secretary.

Delaware Medical Society of, Wilmington, Oct. 8-10. Dr. W. H. Speer, 917 Washington St., Wilmington, Secretary.

Indiana State Medical Association, French Lick, Nov. 6-8. Mr. Thomas A. Hendricks, 23 E. Ohio St., Indianapolis 4, Secretary.

Kentucky State Medical Association, Lexington, Oct. 29-31. Dr. P. E. Blackerby, 620 S. Third St., Louisville, Secretary.

New York Medical Society of the State of, House of Delegates, Buffalo, Oct. 8-9. Dr. W. P. Anderton, 292 Madison Ave., New York 17, Secretary.

Omaha Mid-West Clinical Society, Omaha, Nebraska, Oct. 22-26. Dr. R. W. Fouts, 107 S. Seventeenth St., Omaha, Secretary.

Pennsylvania Medical Society of the State of, House of Delegates, Philadelphia, Oct. 23-24. Dr. Walter F. Donaldson, 500 Penn Ave., Pittsburgh 22, Secretary.

Southern Medical Association, Cincinnati, Nov. 12-15. Mr. C. P. Loran, Empire Bldg., Birmingham 3, Alabama, Secretary.

Tennessee State Medical Association House of Delegates, Nashville, Oct. 20-21. Dr. W. M. Hardy, 706 Church St., Nashville, Secretary.

Virginia Medical Society of, House of Delegates, Roanoke, Oct. 22-23. Miss Agnes V. Edwards, 1200 Clay St., Richmond 19, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Dr. Peers Resigns as Mayor of Colfax.—Dr. Robert A. Peers, a member of the Board of Trustees of the American Medical Association and formerly president of the California Medical Association, on July 10 resigned from the city council and as mayor of Colfax. Dr. Peers first was elected to the city council in 1921 and was chosen mayor of the city the following year.

Heart Association Meetings.—The annual postgraduate symposiums on heart disease held under the auspices of the California Heart Association will be given as follows:

San Francisco, October 17-20. Physicians may register with the San Francisco Heart Committee, 604 Mission Street, San Francisco 5.

San Diego, October 22. Symposium sponsored by the San Diego County Medical Society.

Los Angeles, October 24-26. Physicians may register with the Los Angeles Heart Association, 117 West 9th Street, Los Angeles 15.

Included among the guest speakers will be Dr. Samuel A. Levine, Boston; Col. Irving S. Wright, M. C., and Dr. James J. Waring, Denver.

Grant for Epilepsy Research.—Research now in progress on the control or prevention of epilepsy will be aided by a grant from C. S. Morse, San Francisco, according to an announcement from Robert G. Sproul, LL.D., president of the University of California, Berkeley, in the *University of California Club Sheet*, September 18. Within the next three years \$9,000 will be given to supplement the Mother Lode Fund, which was established to finance epilepsy in the department of neurology under Dr. William J. Kerr, professor of medicine in the medical school on the San Francisco campus of the university (THE JOURNAL, March 17, p. 663).

DELAWARE

State Medical Meeting in Wilmington.—The one hundred and fifty-sixth annual session of the Medical Society of Delaware will be held at the Academy of Medicine, Wilmington, October 8-10, under the presidency of Dr. I. Lewis Chipman. Among the speakers will be:

Dr. William H. Speer, Wilmington, Excerpts from Activities of Other State Societies.

Dr. Frederick H. Allen, Philadelphia, Mental Hygiene in Children.

Dr. Temple S. Fay, Philadelphia, Problems of Rehabilitation in Patients with Cerebral Palsy.

Dr. Karl M. Hauser, Philadelphia, Early Malignancy of the Larynx: Its Detection and Treatment.

Lieut. Arthur G. Lueck (MC), Use and Efficacy of Sulfonamides and Penicillin.

Comdr. Fred A. Butler (MC), Pacific Tropical Diseases. Their Management and Postwar Implication.

Dr. Joseph C. Birdall, Philadelphia, Pyelitis—Early Symptoms, Diagnosis and Treatment.

Dr. William Bates, Philadelphia, Early Determination of Gallbladder Disease and Treatment.

Dr. Paul C. W., Procurement and Assignment.

Lieut. Col. George O. Lison, M. C., Prominent Medical Conditions and Treatment in the Pacific Area.

Lieut. Col. George O. Lison, M. C., Initial Treatment and Methods of Transportation in Fractures of the Long Bones.

Capt. Lewis K. Ferguson (MC), Treatment of Chest and Abdominal Wounds.

Dr. John O. Griffith Jr., Philadelphia, Hypertension—Some of the Results with Later Methods of Treatment.

DISTRICT OF COLUMBIA

Personal.—Major General George C. Dunham, president of the Institute of Inter-American Affairs, was recently awarded the distinguished service medal for his work in advancing the development of Latin America. The citation accompanying the medal read in part that, "through his exceptional performance in discharging duties of great responsibility, large populations in the other Americas have benefited from expanded health and sanitation facilities, standards of living have been raised, and important forward steps have been taken in cooperative effort toward the economic development of the hemisphere." General Dunham has been with the Office of Inter-American Affairs since 1942, directing since that time the most extensive long range Inter-American health and sanitation program ever attempted, according to the *Newsletter of the Health and Sanitation Division of the Institute of Inter-American Affairs*.

FLORIDA

Special Society Election.—Dr. John A. Pines, Orlando, was elected president of the Florida Radiological Society at Orlando recently. Other officers include Drs. Charles M. Gray, Orlando, vice president, and James F. Pitman, Lake City, secretary-treasurer.

ILLINOIS

Special Society Election.—Dr. John J. Madden was chosen president of the Illinois Psychiatric Society at its annual meeting recently. Other officers include Drs. Frances Hannett, vice president, and Charlotte G. Babcock, secretary-treasurer, all of Chicago.

Chicago

Personal.—J. Milo Anderson, assistant superintendent of the University of Chicago Clinics and superintendent of the Chicago Lying-In Hospital and Dispensary, was to take over a new appointment as administrator of the Methodist Hospital, Gary, Ind., August 15.

Gift for Cancer.—Northwestern University has received \$10,000 to establish a fund for "research into the cause and cure of cancer and the amelioration of suffering from that disease." The gift was made by Miss Edith L. Patterson as a memorial to her brother, Floyd Elroy Patterson, to augment a contribution of \$575,000 made to Northwestern University in 1933 for the maintenance of the Patterson Cancer Clinic on the Chicago campus and to serve as a nucleus to establish the new fund.

INDIANA

Personal.—Dr. George W. Boner, North Vernon, has been appointed superintendent of the Madison State Hospital, North Madison, to succeed Dr. Love E. Pennington, resigned.—Dr. Robert M. Maurer, Brazil, has been named health commissioner of Clay County to succeed Dr. Lewis C. Rentschler, Clay City, who resigned because of ill health.

Phi Delta Epsilon Lecture.—Lieut. Col. Truman G. Blocker Jr., M. C., chief of plastic service, Wakeman General Hospital, Camp Atterbury, on July 20 gave the Phi Delta Epsilon Lecture sponsored by the fraternity at the Indiana University Medical Center, Indianapolis. His subject was "Plastic Surgery of War Wounds." A feature of the meeting at which the lecture was given was the presentation to Donald P. Morgan, Indianapolis, junior student in the medical school, of the John F. Barnhill Award for excellence in freshman anatomy.

KANSAS

Changes in Health Officers.—Dr. Harold O. Bullock, Independence, has been made health officer of Montgomery County on a temporary part time basis, succeeding Dr. Blair Points, who resigned July 20. Dr. Fred E. Torrance, Winfield, was named on a similar basis in Cowley County, succeeding the late Dr. Forrest A. Kelley.

First Postgraduate Course.—The University of Kansas School of Medicine, Kansas City, will conduct its first postgraduate course October 29-November 2. The course is designed as a review especially to assist men who have been in service, but a general invitation is extended to all physicians in the state. Applications may be sent either to Dr. Harry R. Wahl, dean of the school of medicine, Kansas City, or to Mr. Harold G. Ingham, director of the extension division, Lawrence. Dr. Edward H. Hashinger, Kansas City, Mo., has been appointed acting director for the graduate medical program. Among the instructors participating in the course will be Drs. Joseph A. Capps, Chicago, on "Pleural Shock"; Herbert A. Wenner, New Haven, Conn., "Polymyositis," and Albert D. Ruedemann, Cleveland, "Differential Diagnosis of the Red Eye."

Expanded Mental Facilities.—Plans are now being completed to provide the University of Kansas Hospital, Kansas City, with enlarged facilities for the treatment of mental patients and for the instruction of medical school students in the specialized line. A former convalescent ward was converted into a psychiatric ward, equipped to serve about 25 patients at a time. It was hoped that the new unit would be completed October 1. According to the *Journal of the Kansas Medical Society*, the addition of the ward was made possible by a \$10,000 appropriation for remodeling and equipment granted by the last Kansas legislature. Another bill gave the probate court authority to send a person to the school of medicine for diagnosis and recommendation as to whether or not he should be committed to a state institution. The new facilities will be used primarily as a diagnostic center, and it is

planned that patients will be short time patients. Organization of the staff has not been completed, but it will be directed by members of the department of neurology and psychiatry of the school of medicine, who will also serve as instructors.

LOUISIANA

Wilbur Smith Named Dean at Louisiana.—Dr. Wilbur C. Smith has been appointed dean at Louisiana State University School of Medicine, New Orleans, to succeed Dr. Beryl I. Burns, resigned effective September 1.

MONTANA

Hospital Survey.—A study to determine the need of hospital construction in Montana is nearing completion. Medical members of the more than twenty members who carried out the study include Dr. Edythe P. Hershey and Dr. Burton K. Kilbourne of Helena, who are on the staff of the state board of health. There are three other physicians on the board: Drs. James C. Shields, Butte, Maurice A. Shillington, Glendive, and E. Martin Larson, Great Falls.

NEBRASKA

Hospital Observes Seventy-Fifth Anniversary.—The Creighton Memorial St. Joseph's Hospital, Omaha, observed its seventy-fifth anniversary September 19 with a banquet. The first patient was admitted to the hospital Sept. 25, 1870. Dr. Bryan M. Riley, an alumnus and former dean of Creighton University School of Medicine, and Dr. John W. Duncan, graduate of the class of 1912 at the university and a former intern at St. Joseph's Hospital, reviewed the history of the institution. A feature of the meeting was the presentation of \$1,000 by the staff to the Sisters of St. Francis to improve the facilities of the chapel of the hospital.

Ordinance to Improve Omaha's Health.—On September 19 an ordinance was introduced in the city council of Omaha to establish an Omaha board of health and provide for a full time health director. The ordinance was proposed by a specially appointed committee named by Mayor Leeman to submit recommendations for reorganization of the city health department. Members of the committee included Drs. Charles W. M. Poynter, dean of the University of Nebraska College of Medicine, chairman, and Dr. Charles M. Wilhelm, dean of Creighton University School of Medicine, Dr. Roy W. Fouts, Dr. J. Jay Keegan and Seymour Smith, attorney, legal adviser. The ordinance proposes that the mayor, the superintendent of schools, an Omaha physician who has practiced in the city at least ten years and two public minded residents constitute the new board of health and serve without pay. The board would have charge of all public health activities and would appoint the health director subject to council approval. The local health department has up to now been under the mayor's supervision. A health commissioner appointed by the mayor and approved by the council has been in direct charge on a part time basis.

Midwest Clinical Assembly.—The thirteenth annual assembly of the Omaha Mid-West Clinical Society will be held at the Hotel Paxton, Omaha, October 22-26. Among the speakers will be:

Dr. Guy A. Caldwell, New Orleans: Treatment of Chronic Osteomyelitis.

Dr. Charles A. Donn, Columbus, Ohio: The Purpuric States.

Dr. Lester R. Drigstedt, Cheyenne: Newer Developments in the Surgical Treatment of Gastrointestinal Ulcers.

Dr. Elmer Belt, Los Angeles: Prostatic Obstructions in Age Groups: Early Infancy to Great Age.

Dr. Henry P. Wagner, Rochester, Minn.: Loss of Vision in Patients with Hypertensive Disease and with Diabetes.

Dr. Archibald D. Campbell, Montreal: Quebec Canada: Prenatal Care and the Interpretation of Certain Symptoms Suggestive of Toxemia of Pregnancy.

Dr. Burrill B. Crohn, New York: Peptic Ulcer as a Modern Concept of a Psychosomatic Disease.

Dr. Alvin R. Moritz, Boston: Death by Violence or Under Suspicious Circumstances: The Medical and Legal Responsibilities of the Attending Physician.

Dr. Sylvester N. Berens, Seattle: Ruptured Intervertebral Disk—An Orthopedic or Neurologic Problem?

Dr. Robert H. Felix, Washington, D. C.: Maladjustment in the Returning Veteran: Comments on Etiology and Symptomatology.

The program will also include clinics and round table discussions. A panel discussion on military medicine will include:

Lieut. Col. Donald J. Wilson, M. C.: Lichenoid Dermatitis.

Lieut. Col. Francis Murphy, M. C.: Prolapsed Intervertebral Disk in the Cervical Region.

Major Thomas I. Dray, M. C.: Trench Foot—Medical Consideration.

Col. John B. Cron, M. C.: Surgical Management of the Unexpended Lung.

Major Joseph E. Milgram, M. C.: Functional Recovery from War Wounds of the Extremities.

NEW YORK

Regional Teaching Day.—"Psychotherapy in General Medicine" will be the theme of a regional teaching day program at the Hudson River State Hospital, Poughkeepsie, October 10, under the auspices of the Dutchess County Medical Society and the Medical Society of the State of New York. Among the speakers will be:

Dr. Teshe A. Osborn: Buffalo: Recognition and Management of Psychiatric Problems in General Practice.

Dr. James H. Wall, White Plains, N. Y.: Psychiatric Aspects of Obstetrics and Gynecology.

Dr. Foster Kennedy, New York: The Neuroses Related to the Mince Depressive Constitution.

District Meeting.—The thirty-ninth annual meeting of the Seventh District Branch of the Medical Society of the State of New York was held at the Clifton Springs Sanitarium and Clinic, Clifton Springs, September 27, under the presidency of Dr. Homer J. Knickerbocker, Geneva. Among the speakers were:

Dr. Edwin C. Foster, Penn. Yarn, Group Practice: Advantages, Disadvantages, Organization and Costs.

Mr. George P. Farrell, director of bureau of medical care insurance: Medical Society of the State of New York, City Prepaid Medical Care Insurance.

Dr. Albert M. Crance, Geneva: Modern Trends in Urology and Their Application to General Practice.

Dr. Leslie B. Mahoney, Rochester, Burns: New and Improved Treatments.

New York City

The First Harvey Lecture.—Dr. James A. Shannon will deliver the first Harvey Lecture in the annual series sponsored by the Harvey Society in affiliation with the New York Academy of Medicine. The lecture will be given October 25 on "Chemotherapy in the Human Malaras."

Antirabic Clinic Opened.—An antirabic clinic in the borough of Queens was reopened in new quarters in Jamaica August 27. The clinic, which has been closed for more than two years, was opened again as a result of the discovery of three rabid dogs in Queens since June 28. Dr. Joseph Steisel is the physician in charge.

Ban on Sale of Antibiotic Drugs Lifted for Bandages Containing Tyrothricin.—At a meeting September 11 the New York City Department of Health approved an exception to the sanitary code to permit the sale of the antibiotic drug tyrothricin without a prescription and within a specified concentration on bandages for external application to the human skin. In announcing the exception Dr. Ernest L. Stebbins, health commissioner, emphasized the fact that the sale of all other antibiotic drugs, including penicillin, still requires the written prescription of a physician, dentist, podiatrist or veterinarian.

PENNSYLVANIA

Personal.—Dr. Sarah I. Morris, Philadelphia, has been appointed resident physician and professor of hygiene at Wilson College, Chambersburg. It was reported September 5 Professor of preventive medicine at Woman's Medical College of Pennsylvania since 1931, Dr. Morris was also director of the student health service of that institution for ten years. She had previously been associate professor in the clinical medical department of the University of Wisconsin Medical School, Madison, and a member of the university's student health department.

Philadelphia

Regional Course on Cancer.—The first of a projected series of regional postgraduate courses to be sponsored by the commission on education of the American College of Radiology in conjunction with selected teaching institutions will be conducted during the week of February 4 at the Philadelphia County Medical Society Building. This first and experimental course will be jointly sponsored by the college and the Philadelphia Roentgen Ray Society. Topics to be discussed include:

February 4: practical consideration of therapy problems concerned with the physics of radium and roentgen rays.

February 5: carcinoma of the female genital tract.

February 6: carcinoma of the breast.

February 7: carcinoma of the head and neck. The Philadelphia Roentgen Ray Society meeting is in the evening.

February 8: carcinoma of the skin and treatment of infections.

February 9: radiation treatment of blood dyscrasias and lymphoblastomas. Cancer detection clinics and important developments in cancer research.

It is proposed to give each registrant a mimeographed outline of the entire course. The program will be arranged to permit a round table discussion of practical problems. Subjects to be presented will include the pathologic, clinical and therapeutic aspects of the conditions under consideration. Teachers will be drawn from the fields of radiotherapy, sur-

gery, oncology, physics, biophysics and pathology. Advance registration may be made by writing to the Commission on Education of the American College of Radiology, 20 North Wacker Drive, Chicago 6.

TEXAS

Alumni-Faculty Foundation Created at Baylor.—The Baylor University College of Medicine, Houston, Alumni-Faculty Foundation has recently been organized "to promote and further medical education in the state of Texas by establishing an endowment and foundation in the interest of the welfare of the college of medicine of Baylor University and for aiding and extending the work and medical activities of the said college of medicine." Officers include Drs. Elisha F. Robbins, president; Herman W. Johnson and Henry A. Petersen, vice presidents, and Thomas P. Kennerly, secretary-treasurer. A group of twelve trustees has also been named. One of the activities of the newly established foundation is the creation of a lectureship in memory of those alumni who died during World War II.

Conference on Pediatrics.—A conference in pediatrics under the joint auspices of the University of Texas Child Health Program and the maternal and child health division of the Texas State Board of Health will be held at the University of Texas Medical Branch, Galveston, November 12-17. The program, arranged by Dr. Arild E. Hansen, professor of pediatrics, will include as speakers Drs. Alton Goldbloom, McGill University Faculty of Medicine, Montreal; Clifford G. Grulec, Rush professor of pediatrics, University of Illinois College of Medicine, Chicago; Joseph A. Johnston, pediatrician-in-chief, Henry Ford Hospital, Detroit; Rustin McIntosh, professor of pediatrics, Columbia University College of Physicians and Surgeons, New York; and Irvine McQuarrie, professor of pediatrics, University of Minnesota Medical School, Minneapolis. The conferences on pediatrics arranged by the University of Texas Child Health Program are supported by the William Buchanan Foundation of Texarkana.

Personal.—Simon Edward Sulkin, Ph.D., has been promoted to be professor of bacteriology and immunology of Southwestern Medical College and chairman of the department. The news item that appeared in *THE JOURNAL*, September 8, page 142, stating that Dr. Sulkin was acting chairman of the department was received from the Southwestern Medical Foundation. —Dr. Warren Andrew, associate professor of histology and embryology, Southwestern Medical College, Dallas, will carry on research during the next four months at the laboratory for histologic research of the medical school of the National University of Uruguay, Montevideo, it was reported in September. Dr. Andrew's work, which involves a study of microscopic changes in the body with advancing age, will be done in collaboration with Dr. Julio M. Sosa, director of the laboratory, and their findings will be published in both Spanish and English. The project is under the auspices of the Uruguayan government and of the U. S. Department of State.

VIRGINIA

Graduate Course in Ophthalmology.—The nineteenth annual spring graduate course in ophthalmology and otolaryngology will be held at the Gill Memorial Eye, Ear and Throat Hospital, Roanoke, April 1-6, 1946.

Personal.—Dr. Elbyrne G. Gill, Roanoke, was recently appointed chairman of the city board of health and Dr. William R. Whitman vice chairman. —Dr. Ramon D. Garcin Sr. was recently named chairman of the Richmond Public Library Board, succeeding the late Dr. Beverley R. Tucker. —Dr. Charles Preston Pope Jr., Aiken, S. C., has been appointed health officer of the Pulaski-Wythe Health District, effective August 1.

Memorial for Physician.—According to the *Virginia Medical Monthly*, the sum of \$10,000 has been provided in the will of the late Mrs. Sallie B. Twymann as a memorial to her late husband for the establishment in the University of Virginia Department of Medicine, Charlottesville, of the Frederick W. Twymann Fund. The income is to be applied for research in cardiovascular disease under the direction of the department of internal medicine.

Fund for Blind Honors Physician.—Under the will of the late Mrs. Nellie Porterfield Dunn, widow of Dr. John W. Dunn, Richmond, a bequest is provided to benefit blind persons. There is also a stipulation that a residence at 411 East Franklin Street, Richmond, is to become a part of the

"John Dunn Fund for the Blind" and some provisions for grants to blind persons who complete courses at vocational schools in order to allow for the interval between leaving school and finding employment.

WEST VIRGINIA

Personal.—Dr. William J. Habeeb has resigned from the staff of the Pinecrest Sanitarium, Beckley, to become superintendent and medical director of the Clark County Tuberculosis Sanatorium, Springfield, Ohio. —Dr. Benjamin I. Golden, Elkins, was recently appointed chief medical adviser for the West Virginia Department of the American Legion.

District Health Conferences.—"Public Health and the Returning Veteran" and "Sanitation in the Schools" will be the themes of a fall health conference of the Southern District to be held at Beckley October 11. "Public Health and the Rehabilitation Program" and "Interrelation Between the Field Worker and the State Hygienic Laboratory" will be the topics discussed at a similar conference in the Northern District at Wheeling, October 19.

Seminars on Psychiatry.—The psychiatric committee of the West Virginia State Medical Association has completed arrangements for the first of a series of regional seminars on psychiatry to be held in this state under the program adopted by the committee. Night meetings have been scheduled for Morgantown October 10, Huntington October 11 and Bluefield October 12. The meetings sponsored by the committee will be held under the auspices of local medical societies. Guest speakers will be Drs. Wendell S. Muncie, Baltimore, and Dale C. Cameron, Bethesda, Md. Additional seminars are being arranged for other cities in the state later in the year and early in 1946.

PUERTO RICO

Establishment of Health Centers.—An extensive program of public health services is now being considered by the department of health of Puerto Rico to construct two hundred public health centers in the rural areas of the island at a proposed cost of several million dollars. Sites have already been selected, each center to have a full time medical officer and a graduate nurse. A part of the program will be the cooperation of the public health units and the municipal hospitals to carry out a unified plan. The island of Puerto Rico has been divided into four public health districts, with a medical officer in charge of each. Special cancer services will be conducted under the auspices of the Puerto Rico Cancer Institute.

Hospital News.—Dr. Antonio Fernos-Isern, San Juan, commissioner of health of Puerto Rico, has recommended to the legislature and the planning board a plan to provide at least a hospital bed for each thousand inhabitants in each municipality of the island, to be carried out during the next two years. There are said to be forty-three of the seventy-seven municipalities on the island without hospital facilities at the present. There are thirty-four municipalities that have a bed for each thousand inhabitants or more. Cost of repairs, reconstruction or remodeling in the first group is estimated at \$1,075,000, while estimates have not been made for the second group. The report indicates that the legislature has passed bills appropriating \$550,000 to aid municipal hospitals, but the amount is considered insufficient.

GENERAL

Louis Neff Placed in Charge of Cancer Society's Office.—Mr. J. Louis Neff, recently appointed executive director of the American Cancer Society, New York (*THE JOURNAL*, Dec. 25, 1943, p. 1129) has been placed in full charge of the society's headquarters office, subject to the authority of the executive committee of the board of directors of the society. Mr. Neff is taking charge following the resignation of Rear Admiral Charles S. Stephenson (MC), U. S. Navy, retired, as acting managing director (*THE JOURNAL*, June 9, p. 454).

Anniversary of Discovery of X-Rays.—The fiftieth anniversary of the discovery of the x-rays will be nationally observed November 5-10 under the sponsorship of the American College of Radiology. The anniversary celebration will mark the development of x-rays as a medical instrument and call public attention to the uses of radiology in the diagnosis and treatment of disease. It will also seek to educate the public to the services of the radiologist, a physician who specializes in the medical applications of the x-rays, devoting his skill to the interpretation of x-ray films for diagnosis and the application of x-rays in the treatment of many maladies.

Association of American Medical Colleges.—The fifty-sixth annual meeting of the Association of American Medical Colleges will be held at the William Penn Hotel, Pittsburgh, October 29-31, under the presidency of Dr. Albert C. Furstenberg, Ann Arbor, Mich. The University of Pittsburgh School of Medicine will be the host. The speakers will include:

Kenneth W. Vaughn, Carnegie Foundation, New York, The Graduate Record Examination.
Dr. William Worth Hale, Boston, Measurement of Aptitude for Medicine.
Carlyle F. Jacobsen, Ph.D., St. Louis, subject not announced.
Tom Jones, Chicago; Lewis Waters, Ph.D., Dallas; Harry E. Morton, Ph.D., Philadelphia; Joseph E. Markee, Ph.D., Durham, N. C., and Comdr. Dean F. Smiley (MC), Visual Education.
Dr. Edward R. Murgage, Denver, Appointment and Tenure of Faculty of Professional Rank.
William T. Sanger, LL.D., Richmond, Va., What the Educator Thinks the Ideal Medical Curriculum Should Be.
Dr. Tinsley R. Harrison, Dallas, Tradition: The Rivet in the Medical Curriculum.
Harold Cummins, Ph.D., New Orleans, Embryology in the Medical Curriculum.
Dr. Alexander H. Colwell, Pittsburgh, subject not announced.

Civilian Defense Activities Merged with Red Cross.—Under a spirit of cooperation that has existed between the U. S. Office of Civilian Defense and the American National Red Cross since the creation of the former, recommendations have been made to consolidate all emergency medical services with the Red Cross disaster service. Chapter chairmen of the Red Cross have been advised with the approval of Dr. George Baehr, formerly chief medical officer of the U. S. Office of Civilian Defense, to communicate with commanders of civilian defense corps and with the local chiefs of emergency medical service to discuss the consolidation. The U. S. Office of Civilian Defense was closed July 1. The emergency medical service available through the state and local organizations has proved to be an invaluable community asset and should not be allowed to disintegrate, according to Dr. Baehr. The proposed consolidation with the Red Cross disaster service would serve to make it a permanent part of the community resources, a plan which has already been carried out in some communities. On August 7 Dr. Baehr directed a letter to state and local emergency services urging their cooperation with the Red Cross disaster service in the proposed consolidation.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended September 22 have been received from the division of public health methods, U. S. Public Health Service, as follows:

Joe Savage Joins National Foundation.—Major Joe W. Savage, for seventeen years executive secretary of the West Virginia State Medical Association, has accepted a position with the National Foundation for Infantile Paralysis, with headquarters in New York. He will work directly under Basil O'Connor, president. Major Savage was released from active duty with the Army Air Forces on September 1 after serving for more than three years with the AAF training command for navigators at various air fields in Texas. At the time of his separation he was director of military training

at San Marcos Army Air Field, San Marcos, Texas. During World War I Major Savage served as an army pilot in France for over two years. Major Savage has had some former experience with the national foundation. During the March of Dimes campaign in 1941 he was granted a leave from the state medical association to assist the national foundation drive. Following four months' service with the foundation he continued to be organizational consultant for several months, visiting local chapters in every part of the United States. Major Savage was at Warm Springs, Ga., several days in September and was to start his new duties in New York the first of October.

LATIN AMERICA

Health Activities in Latin America.—*Visitors to the United States.*—Sylvia Hasselmann, chief of the vital statistics department of the Brazilian Public Health Service, arrived in Miami from Rio de Janeiro July 27 to make a tour of hospitals in the United States. Dr. Herman Bennett of the Chilean Health department arrived July 27 in Miami on his way to Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, to make a study of blood transfusions. Dr. Julio Roberto Herrera, director general of public health of the Republic of Guatemala, has gone to the United States to make a study of public health services. Dr. Herrera studied under a Rockefeller Foundation fellowship at Johns Hopkins University in 1937, receiving the degree of master in public health from the Johns Hopkins University School of Hygiene and Public Health.

Industrial Hygiene Program in Chile.—In preparation for launching a nationwide program in industrial hygiene, the republic of Chile has sent a number of its nationals for training to the United States, according to the *Industrial Hygiene News Letter*. The training is a part of a program for reorganization of the Chilean public health services in cooperation with the Institute of Inter-American Affairs, the Rockefeller Foundation, the Pan American Sanitary Bureau and the Commonwealth Fund. Most recent trainees have been Dr. Alejandro Forero, chief of the Santiago Industrial Hygiene Office of the Chile Public Health Service, who will head the new industrial health service, and Carlos Valenzuela, Ch.Eng., M.Sc. They have just completed their training period. Dr. Forero at Columbia and Mr. Valenzuela at Harvard. Following this training, these men are observing the work of the U. S. Public Health Service Industrial Hygiene Division and various state industrial hygiene laboratories, as well as laboratories of non-official agencies and private industries. On their return to Chile, Dr. Forero and Mr. Valenzuela will organize and teach a course in industrial health in the University of Chile, Santiago. The industrial health course, organized as a part of the public health school of the University of Chile, will offer training to public health personnel, industrial physicians, chemists and engineers, who will then be sent to the United States for further instruction. Authorities in the United States are to be invited to Chile as visiting lecturers and consultants. It is hoped to complete a reorganization of the general program in public health as soon as possible under the direction of Dr. Nacianceno Romero, general director of health. By 1951 it is expected that enough industrial health workers will have been trained to serve the whole nation, with industrial hygiene units established in the main mining and industrial centers and in every important city.

Public Health Libraries.—The National Medical and Public Health Library has been established in the new health center building in Managua, Nicaragua. Books, pamphlets and periodicals of the Direccion General de Sanidad, the Servicio Cooperativo Interamericano de Salud Publica and the Institute of Inter-American Affairs form the nucleus of the library, which is said to be the first of its kind in the republic of Nicaragua. A cooperative arrangement has been made with the American Library of Nicaragua, also located in Managua, where books of that library on medical and allied subjects are listed in the health center library and may be used by staff members and other persons. In Brazil, the library of the Servicio Especial de Saude Publica was established in July 1944 under its health education division. It is a medical library specializing in hygiene, public health and health education.

Hospital News.—Funds with which to construct a tuberculosis hospital in Panama will be derived from a 2.5 per cent increase in the taxes imposed on wagers at horse race tracks, President Enrique Jimenez announced recently. The Republic of Panama is said to have one of the highest tuberculosis rates in the world.

LONDON

(From Our Regular Correspondent)

Sept. 8, 1945.

The World Control of Narcotic Drugs

A meeting of the Permanent Central Opium Board has been held in London. The president, Sir Atul Chatterjee, described the world drug position. The board wishes to return to the prewar conditions of control. All countries signatory to the conventions (that is, every considerable country excepting Argentina) are required to send in estimates of their needs of narcotic drugs for consumption, manufacture or export for the coming year. These are examined by the Supervisory Commission—an allied organization to the board—and no country is allowed any excess of the figure without submitting a supplementary estimate. At the beginning of the war every government was asked to keep intact national control and to collaborate with the board in international control. But during the war some retrogression has taken place in many countries, especially those with colonies. In normal times the board received some 1,500 returns annually from governments. By 1941 this had fallen to 1,000. The axis or axis occupied countries are the chief defaulters, but Russia ceased sending when it severed connection with the League of Nations. Control is being resumed or continued in Belgium, the Netherlands and Scandinavia. In South America the situation varies. Control is satisfactory in Colombia and, though Argentina has not ratified the convention, that country sends full returns. In Peru, a cocaine exporting country, there has been great improvement, but in Panama and some other places in Central and South America control hardly exists.

Secondary Diphtheritic Infection of Empyema and Thoracotomy Wounds

In *Guy's Hospital Reports* R. C. Brock points out that, while secondary diphtheritic infection of chronic skin lesions is widely known, the fact that it can occur in a wound due to war, accident or operation may be overlooked, with disastrous consequences. Chest wounds are particularly liable to be attacked, presumably by way of the upper respiratory passages but also by direct infection. Brock has several times observed diphtheritic infection of the chest wounds of acute or chronic empyema, lobectomy and pneumonectomy. His first experience was in a young man with chronic empyema who came to the hospital complaining of paralysis of the legs. Examination revealed severe peripheral neuritis of motor type affecting the lower limbs. In the discharge from the wound an organism was found which gave a positive test for diphtheria in a guinea pig. Under rest and antitoxin the paralysis slowly resolved. How dangerous the complication may be is shown by the fact that during the last ten years Brock has seen five outbreaks of diphtheritic infection in wards devoted to thoracic surgical cases. In each outbreak deaths occurred. In three outbreaks a patient was submitted to thoracotomy before the presence of infection in the ward was recognized. In one outbreak several nurses contracted diphtheria, one of whom died. Several patients also developed faucial diphtheria. In only one outbreak was there ground for the suspicion that any nurse or member of the staff might have been the carrier responsible.

Although much has been written on diphtheritic infection of wounds in general, references to thoracic wounds are few and there appears to be none in English literature. But German literature of the last war recognized the condition, and one writer stated that "empyema wounds were particularly liable to infection." Outbreaks were also reported in American military hospitals in the last war. Simmons and Bigelow in 1919

described the rapid spreading of infection to as many as 60 empyema wounds. Response to immediate quarantine and vigorous treatment was poor. It was suggested that the reason why all local methods proved unsatisfactory was that the bacilli grew deep in the granulations. Frequently when superficial cultures were negative the organisms could be readily obtained by curetting.

In Hurst's *Medical Diseases of the War* Harries (1943) gave a valuable account of cutaneous and wound diphtheria: "In the early stage of infection the wound becomes painful and reddened. There is at first an irritating serous discharge, which is replaced in a few hours by a more or less typical pseudomembrane gray or grayish yellow, thin or thick. If the membrane is removed, it reforms. The edges of the wound may either become livid, infiltrated and definitely raised (phlegmonous type) or undermined with fetid pus, in which case they are not invariably reddened (ulcerative type). Vesicles may form on the edges of the wound; these may rupture and then become covered with pseudomembrane." Other writers have described the appearance of the wounds as varying and in no way typical. Brock noticed nothing characteristic; some of the wounds were red and angry, others merely indolent and discharging pus. Tincture of iodine has been recommended as the best application. Once established in a ward, the infection rapidly spreads. The only course is to stop all admissions and send the patients to an isolation hospital. Antitoxin should be given at once and in full doses.

BRAZIL

(From Our Regular Correspondent)

RIO DE JANEIRO, Sept. 15, 1945.

Allergy to *Ascaris Lumbricoides*

Dr. M. Rocha e Silva of the Biological Institute of São Paulo has performed, since March of last year, a series of experiments to ascertain the mechanism of the shock produced in dogs by the extract from *Ascaris lumbricoides*. According to a recently published report the precipitated, dialyzed and deproteinized extracts of *Ascaris* apparently contain a glycogen-like material and a proteose-like substance which, introduced intravenously in doses of 5 to 10 cc., produce in dogs a group of severe symptoms indistinguishable from true anaphylactic shock: enormous engorgement of the liver, increased pressure in the portal vein, abdominal hyperemia and a decided fall of the carotid blood pressure. Since the animals did not receive a preparatory injection of the extract, the shock was attributed to an endogenous, spontaneously acquired sensitization of allergic type, due to the presence of parasites in the intestinal tract. The situation seems to be similar to Van Es and Schalk's finding of an anaphylactic-like shock in horses intravenously injected with extracts from larvae of *Gastrophilus intestinalis*, a parasite common in the digestive tract of those animals. Enormous increases in blood histamine, especially at the trunk of the portal vein, were observed.

Experiments of perfusion of the isolated liver were performed in order to clarify the mechanism of the discharge of histamine and heparin. Perfusing the liver with Tyrode's solution or defibrinated blood plus *Ascaris* extract is not enough to discharge the histamine and the heparin previously bound to liver cells. This led to the idea that total blood contains a factor or factors concerned with the reaction. The suggestion that platelets and leukocytes are those factors was considered very probable on the basis of these three facts: 1. Leukocytes and platelets are enormously reduced in the blood immediately after the injection of the extract. 2. Glycogen extracted from dog's liver produces reductions in the leukocytes and platelets of the same order of magnitude as *Ascaris* extracts but do not induce shock. 3. In experiments of liver perfusion with total citrated or oxalated blood, leukocytes and platelets are retained by the liver cells as soon as

the *Ascaris* extract is injected, and at the same time a small discharge of histamine and heparin is observed in most cases. Further experiments have shown that platelets can be found forming enormous aggregates in Giemsa stained smears prepared from pieces of liver taken immediately after the injection of the *Ascaris* extracts, and there was clear indication that those aggregates are disintegrated during the onset of the reaction. The author suggests the hypothesis that products derived from disintegrated platelets (trypsin kinase) might activate the plasma trypsin, and this would be the final mediator for the histamine and heparin discharge from liver cells.

Personal

Dr. Raul David de Sanson has been appointed professor of otorhinolaryngology at the University of Rio de Janeiro. He is one of the leading practitioners of this specialty in the city and was already serving at the university as professor ad interim.

Dr. Fabio C. de Mendonça, director of the Bureau of Sanitary Defense of Harbors and Airports of the National Department of Health, has just left for the United States to meet the director of the health division of the UNRRA for the discussion of some problems in that special field of work.

Dr. J. Bonifacio Medina has been appointed professor of clinical gynecology at the University of São Paulo.

Dr. Godinho dos Santos, surgeon general of the Brazilian air force, and Lieut. José Inis Guimarães of the same service have left for the United States, at the invitation of the American government, to visit military hospitals and other establishments connected with the problems of the health of American soldiers.

BUENOS AIRES

(From Our Regular Correspondent)

Aug. 9, 1945.

Exploitation of Drugs

The Committee for Promoting the Exploitation of Drugs recently requested the collaboration of the authorities of the Institute of Pharmacology and Therapeutics of the Faculty of Medicine of the University of Buenos Aires. The object is to prepare and sell various medical preparations such as atropine, morphine and digitalis, which up to now have been imported. The committee also carries on investigations aimed at intensifying the production of industrial essential substances such as peppermint and lavender and insecticides for use in the country and for export.

Diagnosis of Tuberculosis

The Argentine League Against Tuberculosis recently published the results obtained by x-ray examination of the thorax at the Abreu center. The rate of tuberculosis as it was found in a series of 166,600 persons who had examinations during the years 1940 to 1943 was surprising. A percentage of 7.42 tuberculous patients believed themselves normal and lived with the rest of the family without observing any precautions. A percentage of 2.71 tuberculous patients who believed themselves normal lived without any family. Early tuberculosis among 4,000 persons was found by means of the x-ray examination of the thorax. Early treatment was administered.

Rationing Quinine

The National Department of Public Health recently passed regulations through which buying, prescribing and selling quinine are justified only when the drug is to be used in the control of malaria. Drugstores in malarial zones of the country are allowed to have 10 Gm. of quinine, to be used in serving prescriptions for patients with malaria. The amount of the drug is replaced, with proper authorization, as soon as the owners give an account to the proper authorities of having used the drug in filling prescriptions for patients with malaria.

Congresses

The second South American Congress of Otorhinolaryngology was recently held in the University of Montevideo, Uruguay. Dr. J. M. Alonso was the president. Well known specialists of Argentina, Brazil, Peru, Paraguay, Bolivia, Mexico, Chile, Ecuador and Venezuela attended.

The seventeenth Argentine Congress of Surgery will be held in 1946. The official topics will be the diagnosis and treatment of intussusception in children, the therapy of pseudoarthrosis and the diagnosis and results of operation in cancer of the lung.

The first Argentine Congress of Neurosurgery was organized by the Argentine Medical Association. Dr. Roque Orlando of Buenos Aires is the president of the association. The congress was held at Buenos Aires on Nov. 12 to 18, 1944. There were delegations and official speakers from Chile, Brazil, Bolivia, Paraguay and Uruguay. Official speakers were Drs. Vivado Orsini of Santiago, Chile, Adherbal Tolosa and Paulino Longo of São Paulo, Brazil, and Ramón Melgar, Ramón Carrillo and Enrique Pichón Riviere, all of Buenos Aires. Official topics were clinical symptoms for the prognosis of schizophrenic psychoses, the therapy of algias in neurology and lobotomy in psychiatry.

The seventh National Congress of Medicine of Argentina, which was postponed in 1943, will be held in Buenos Aires April 7 to 14, 1946.

The first gastroenterologic meeting of the Society of Gastroenterology and Nutrition will be held on Rio de la Plata on October 8 and 9. Dr. Oscar Copello will be the president. Official speakers are Dr. Carlos Bonorino Udaondo of Buenos Aires, "Infiltrative Sigmoiditis"; Dr. Mariano R. Castex of Buenos Aires, "Diverticular Sigmoiditis"; Dr. Julio Diez of Buenos Aires, "Surgical Therapy of Noncancerous Diseases of Sigmoid," and Dr. Julio Carrere of Uruguay, "Perisigmoiditis and Complications."

Deaths

Dr. Rafael A. Bullrich of Buenos Aires, who specialized in cardiology, died Oct. 28, 1944 at the age of 67.

Dr. Mariano Alurralde of Buenos Aires, a neurologist and professor of clinical neurology at the Faculty of Medicine of Buenos Aires, recently died.

Prizes

The Bullrich prize for the best article on cardiology during a period of two years was recently established in homage to the late Dr. Rafael A. Bullrich.

Marriages

SAMUEL CLARK ATKINSON, DREW, Miss., to Miss Marjorie Sturtevant Webb in North Plainfield, N. J., August 26.

RICHARD FREDERICK AULICK, St. Louis, to Miss Lillian Pauline Haugen of Madison, Wis., July 7.

GEORGE C. GRAHAM, Bellerose, N. Y., to Dr. MURIEL E. HUENI of Queens Village, June 23.

CARL K. PEARLMAN, Brooklyn, to Miss Agnes E. Branch of Huntington, W. Va., recently.

GEORGE M. KOZURKA, Wilmington, N. C., to Miss Bernice Carey in New Orleans, April 6.

JAMES BATES KITTRILL to Miss Ruth Estelle Hendrick, both of Texarkana, Ark., July 27.

EDWIN CLARENCE MORGAN to Miss Marjorie Larman, both of Russellville, Ky., April 18.

FRANK J. KELLY, Kansas City, Mo., to Miss Dorothy Rita Paige of St. Louis, June 16.

GEORGE PIVTON KILEY to Miss Bessie Browder, both of Shreveport, La., July 14.

LORRAIN ANNA LANLUVILLE, Scranton, Pa., to Mr. C. A. Jones, June 30.

Deaths

Joseph Chauncey Gerard Regan @ Brooklyn; University and Bellevue Hospital Medical College, New York, 1913; born in New York, Sept. 18, 1891; specialist certified by the American Board of Pediatrics, Inc.; member of the American Academy of Pediatrics, Brooklyn Academy of Pediatrics, Brooklyn Clinical Society, Brooklyn Medical Library Association and the Catholic Physicians Guild; formerly on the faculty of the Long Island College Hospital; chairman of the milk commission of the Kings County Medical Society; served on the staffs of the nursery school, St. Joseph's College for Women, the Victory Memorial Hospital, St. Charles Hospital Orthopedic Clinic and St. Catherine's Hospital, all in Brooklyn, the Holy Name Hospital in Teaneck, N. J., and St. Charles Hospital for Crippled Children in Port Jefferson; formerly associated with the Kingston Avenue Hospital; died in Garden City, N. Y., August 15, aged 53.

Henry Roosevelt Craig, Eloise, Mich.; University of Georgia Medical Department, Augusta, 1928; member of the American Psychiatric Association; specialist certified by the American Board of Psychiatry and Neurology; senior psychiatrist at the Eloise Hospital; interned at the Watts Hospital in Durham, N. C.; resident in medicine at the Church Home and Infirmary in Baltimore; formerly assistant in gastroenterology and cardiology at the Henry Ford Hospital in Detroit, graduate assistant in cardiology at the Massachusetts General Hospital in Boston, member of the neurologic service, Boston City Hospital, and physician at the Norfolk Prison Colony in Norfolk, Mass., and the Worcester State Hospital in Worcester, Mass.; died in Ann Arbor, Mich., June 23, aged 41, of acute myoblastic leukemia.

Homer Henderson Wheeler @ Indianapolis; Central College of Physicians and Surgeons, Indianapolis, 1897; served as assistant professor of surgery (proctology) at the Indiana University School of Medicine; member of the American Proctologic Society and the National Gastroenterological Association; fellow of the American College of Surgeons; served during World War I; on the staffs of the Indianapolis City, St. Vincent's and Methodist hospitals; died in the Temple University Hospital, Philadelphia, July 3, aged 72, of cardiovascular collapse.

Osbourn Orlando Ashworth @ Richmond, Va.; Medical College of Virginia, Richmond, 1921; also a graduate in pharmacy; member of the American College of Chest Physicians, Richmond Academy of Medicine, Southern Medical Association, American Heart Association, American Rheumatic Association, Tri-State Medical Society, the Virginia Academy of Science and the American Trudeau Society; interned at St. Elizabeth's Hospital; on the staff of the Stuart Circle Hospital; died in Gloucester County July 5, aged 49, of heart disease.

Henry M. Beckwith @ Joliet, Ill.; the Hahnemann Medical College and Hospital, Chicago, 1897; died in Poplar Bluff, Mo., June 27, aged 78, of injuries received when struck by an automobile.

George Delos Beech @ Rio Hondo, Texas; Rush Medical College, Chicago, 1891; mayor of Rio Hondo; on the staff of the Valley Baptist Hospital, Harlingen; died July 5, aged 77, of heart disease.

John L. Benage, Lebanon, Mo.; St. Louis College of Physicians and Surgeons, 1901; member of the American Medical Association; since 1920 health officer; on the staff of the Wallace Hospital; died June 27, aged 70, of cerebral hemorrhage.

Bolling Sasnett Branham, Powder Springs, Ga.; Atlanta College of Physicians and Surgeons, 1908; member of the American Medical Association and the Medical Association of the State of Alabama; served with the Fairfield Dispensary of the Tennessee Coal, Iron and Railroad Company in Fairfield, Ala.; died July 1, aged 64, of bronchopneumonia.

James Fleming Breakey, Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1894; retired member of the Michigan State Medical Society; member of the American Medical Association; formerly on the faculty of his alma mater; served overseas with Base Hospital number 17 during World War I; on the staff of St. Joseph's Mercy Hospital; died in the University Hospital June 26, aged 75, of carcinoma of the cecum.

John E. Campbell, Brown City, Mich.; Detroit College of Medicine, 1892; served as mayor of Brown City and as a member of the board of education; died June 28, aged 76, of cerebral hemorrhage.

John Canuel, Fall River, Mass.; College of Physicians and Surgeons, Boston, 1935; interned at St. James Hospital in Newark, N. J.; on the staff of St. Anne's Hospital; physician for the state boxing commission; died June 27, aged 41, of acute dilatation of the heart.

John Henry Cleary @ Kenosha, Wis.; College of Physicians and Surgeons, School of Medicine of the University of Illinois, 1902; past president and secretary of the Kenosha County Medical Society; served on medical examining boards during World Wars I and II, receiving commendation from the government for his patriotic and untiring service along these lines; on the staffs of the St. Catherine's Hospital and the Kenosha Hospital, where he died July 20, aged 71, of aplastic anemia.

Edith May Cole, Louisville, Ky.; University of Louisville School of Medicine, 1937; resident physician at St. Mary's Hospital in Athens, Ga.; interned at the Wesley Hospital in Wichita, Kan., and St. Anthony's Hospital; formerly resident physician at the Woman's Hospital in Philadelphia; died in the Jewish Hospital June 14, aged 61, of carcinoma of the uterus.

Thomas Edward Cole, LeMars, Iowa; College of Physicians and Surgeons, Chicago, 1890; died June 7, aged 84, of cancer of the kidneys.

Henry John Collins @ Trenton, N. J.; University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1917; served during World War I; on the staff of the F. W. Donnelly Memorial Hospitals and St. Francis Hospital, where he died June 21, aged 55, of chronic myocarditis and auricular fibrillation.

Byron Bartlett Colvin @ Cleveland; University of Wooster Medical Department, Cleveland, 1908; served overseas during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; on the courtesy staffs of the Huron Road, Charity, St. Alexis and St. Luke's hospitals; served as chief of staff of Woman's Hospital where he died June 20, aged 63, of heart disease.

William Homer Conklin, New York; College of Physicians and Surgeons, Baltimore, 1906; served during World War I; died May 10, aged 61, of cerebral arteriosclerosis with psychosis.

Joseph Bruce Crook @ East Haddam, Conn.; New York Homeopathic Medical College and Flower Hospital, New York, 1913; served as health officer; for many years coroner's medical examiner; a first lieutenant in the medical corps of the U. S. Army during World War I; died in the Middlesex Hospital, Middletown, June 29, aged 59, of abdominal lymphosarcoma.

David Aloysius Flynn, New Haven, Conn.; Yale University School of Medicine, New Haven, 1905; medical supervisor of the Springside Home; died in the Hospital of St. Raphael June 25, aged 65, of bronchopneumonia and heart disease.

Michael Archangel Galgano @ Chicago; University of Illinois College of Medicine, Chicago, 1914; member of the American Urological Association; died July 14, aged 54, of myocarditis.

Eric Julian Gambee, Earlring, Iowa; John A. Creighton Medical College, Omaha, 1917; member of the American Medical Association; served during World War I; died in St. Joseph's Hospital, Omaha, July 5, aged 54, of injuries received in an automobile accident.

George Glucksman, Long Beach, N. Y.; Long Island College Hospital, Brooklyn, 1904; died June 2, aged 63, of pulmonary hemorrhage.

Murray William Goldsmith, New York; Universität Bern Medizinische Fakultät, Switzerland, 1936; died in the Kings Park (N. Y.) State Hospital May 15, aged 35, of pulmonary tuberculosis.

John Joseph Halnan, Paterson, N. J.; University College of Medicine, Richmond, 1907; served in France during World War I; died June 28, aged 65, of chronic hepatitis and myocardial failure.

Clare Heilner Hanley, Scranton, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1905; member of the American Medical Association; served in France during World War I; died June 30, aged 63, of cerebral hemorrhage.

Edward Albert Hanske * Bellevue, Iowa; Louisville (Ky.) Medical College, 1901; died June 21, aged 72, of coronary thrombosis.

Paul Robert Lavin, East Islip, N. Y.; Temple University School of Medicine, Philadelphia, 1932; interned at St. Vincent's Hospital in New York; served a residency at the Central Islip State Hospital in Central Islip, N. Y.; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 26, 1941; service terminated in September 1942; on the staff of the Southside Hospital, Bay Shore; died in West Islip July 6, aged 39, of injuries received in an automobile accident.

Carl Clayton Mann, Rumson, N. J.; University of Buffalo School of Medicine, 1895; died June 1, aged 75.

John Edwin Manney, San Antonio, Texas; Dallas Medical College, 1904; member of the American Medical Association; served during World War I; died in the Medical and Surgical Memorial Hospital May 27, aged 72, of acute ileus, atrophy of the liver and adhesions of the cecum.

George M. Monk, Newton Grove, N. C.; University of North Carolina School of Medicine, 1908; died in the State Hospital, Raleigh, June 27, aged 76, of heart disease.

Edward Lloyd Morrison * Washington, D. C.; Jefferson Medical College of Philadelphia, 1905; specialist certified by the American Board of Ophthalmology; on the staff of the Episcopal Eye, Nose and Throat Hospital; chief of eye service at the Doctors Hospital, where he died August 14, aged 66, of coronary thrombosis.

Guy Ramsey * Sioux Falls, S. D.; Drake University Medical Department, Des Moines, 1901; formerly contract surgeon in the U. S. Army; company physician for John Morrell & Company for two years; died August 19, aged 75, following an operation for carcinoma of the stomach.

Benjamin Lewis Rawlins, Hinsdale, Ill.; University of Pennsylvania Department of Medicine, Philadelphia, 1889; formerly health officer of Hinsdale; for many years associated with the Equitable Life Assurance Company; died July 11, aged 77, of intracranial hemorrhage.

John Herbert Reading Jr., Merion Station, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1917; associate in pediatrics at his alma mater; on the staff of the Hahnemann Hospital; served during World War I; died July 3, aged 55, of cerebral hemorrhage.

Buford Allen Russell, Sherman, Texas; Birmingham (Ala.) Medical College, 1912; member of the American Medical Association; served as health officer of Grayson County; died in the Wilson N. Jones Hospital June 15, aged 57, of carcinoma of the liver.

Henry Alexander Shaw * Pittsburgh; University of Pittsburgh School of Medicine, 1911; died May 14, aged 63, of coronary occlusion and hyperthyroidism.

William Henley Smith * Trenton, N. J.; Jefferson Medical College of Philadelphia, 1917; on the staff of the Mercer Hospital; died June 1, aged 51, of coronary thrombosis.

Robert Hill Tedford * Albany, N. Y.; Albany Medical College, 1893; an Affiliate Fellow of the American Medical Association; died June 26, aged 81, of carcinoma of the colon.

Gilbert Jefferson Thomson, Terre Haute, Ind.; Medical College of Indiana, Indianapolis, 1905; died June 16, aged 70, of myocarditis.

Corlis H. Wallin, Brooksville, Ky.; University of Louisville Medical Department, 1894; member of the American Medical Association; served as health officer of Bracken County; died June 15, aged 72.

Alexander W. Widner * Newtown, Mo.; College of Physicians and Surgeons, Keokuk, Iowa, 1891; Missouri Medical College, St. Louis, 1892; died August 21, aged 76, of pneumonia and coronary thrombosis.

Robert Edward Wilson * St. Louis; Washington University School of Medicine, St. Louis, 1896; for many years medical adviser for the Southwestern Bell Telephone Company; died in the Barnes Hospital July 14, aged 74, of sarcoma of the bladder.

William Johnston Yongue * Lafayette, La.; University of Louisville Medical Department, 1913; died June 6, aged 56, of coronary thrombosis.

John Behan York, Houston, Texas; Medical College of Ohio, Cincinnati, 1896; member of the American Medical Association and the Southern Psychiatric Association; for many years psychiatrist for Harris County; died June 15, aged 73, of uremia.

DIED WHILE IN MILITARY SERVICE

Earl Melvin Anderson, Minneapolis; University of Minnesota Medical School, Minneapolis, 1941; interned at the Minneapolis General Hospital; served a fellowship in surgery at the Mayo Foundation in Rochester, Minn.; commissioned a lieutenant (jg) in the medical corps of the U. S. Naval Reserve on March 3, 1942; promoted to lieutenant; navy flight surgeon; died at the Naval Air Station in Glenview, Ill., July 5, aged 28, of extreme multiple injuries received in an airplane crash.

George Sanford Foster * Manchester, N. H.; Tufts College Medical School, Boston, 1906; began active duty as a lieutenant commander in the medical corps of the U. S. Naval Reserve on Oct. 5, 1942; died in the U. S. Naval Dispensary in Washington, D. C., July 10, aged 63, of arteriosclerotic coronary heart disease.

Joseph Edward Hoenninger, Lancaster, Pa.; Temple University School of Medicine, Philadelphia, 1942; interned at St. Joseph's Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on July 16, 1943; died in Camp Carson, Colo., Oct. 30, 1943, aged 28.

Henry Wilds Patton * Captain (MC), U. S. Navy, Aiea Heights, Hawaii; University of Virginia Department of Medicine, Charlottesville, 1925; diplomate of the National Board of Medical Examiners; interned at the U. S. Naval Hospital in Norfolk, Va.; commissioned an assistant surgeon, lieutenant (jg), in the medical corps of the U. S. Navy on June 4, 1925; rose through the various ranks to that of captain on April 1, 1943; served on the staffs of the naval hospitals at Great Lakes, Ill., San Diego, Calif., and Pensacola, Fla., and as medical officer aboard the carrier *Lexington*, the battleship *New York* and the cruiser *Boise*; while senior medical officer of the transport *Crescent City* he participated in many of the early battles of the Pacific war; served as officer in charge of the hospital corps school in San Diego; at one time executive officer at the U. S. Naval Hospital in Pearl Harbor; executive officer of the U. S. Naval Hospital in Aiea Heights, where he died suddenly June 10, aged 46, of coronary heart disease.

Amos Alexander Plante * Maplewood, N. J.; Columbia University College of Physicians and Surgeons, New York, 1927; interned at the Orange Memorial Hospital in Orange; began active duty as a captain in the medical corps, Army of the United States, on Nov. 12, 1943; assigned to the 216th General Hospital; died in France May 23, aged 45, in an airplane crash.

Kenneth Marshall Sears, Elburn, Ill.; Rush Medical College, Chicago, 1931; member of the American Medical Association; interned at the Wesley Memorial Hospital in Chicago; began active duty as a first lieutenant in the medical corps, Army of the United States, on Jan. 15, 1942; later promoted to captain and major; went overseas in September 1944 and in charge of a hospital train evacuating wounded from the front lines in Paris; died in the Copley Hospital, Aurora, June 2, aged 41, of multiple myeloma, plasma cell type.

Bruce Taylor Smith * Fort Covington, N. Y.; McGill University Faculty of Medicine, Montreal, Que., 1925; interned at the Royal Victoria Hospital in Montreal; began active duty as a captain in the medical corps, Army of the United States, on Aug. 31, 1942; promoted to major; died in the European area Sept. 19, 1944, aged 42, in an airplane accident.

Joseph John Stasko, Chicago; Northwestern University Medical School, Chicago, 1944; interned at the Cook County Hospital; commissioned a lieutenant (jg), medical corps, U. S. Naval Reserve, on Dec. 18, 1943; began active duty Oct. 9, 1944; served overseas for about seven months; died in the Asiatic area June 17 while on the hospital ship U. S. S. *Refuge*, aged 33, of aplastic pernicious anemia.

Talcott Wainwright, Scranton, Pa.; Columbia University College of Physicians and Surgeons, New York, 1933; member of the American Medical Association; interned at the Moses Taylor Hospital and a residency at the Nanticoke (Pa.) State Hospital; began active duty as a captain in the medical corps, Army of the United States, on Sept. 1, 1941; promoted to major; died in the Philippine Islands April 19, aged 41, of coronary thrombosis.

Correspondence

CUTANEOUS HELMINTHIASIS

To the Editor:—In THE JOURNAL, August 11, Wright and Gold referred to *Ancylostoma braziliense* as "a hitherto unreported etiologic factor in the production of Loeffler's syndrome." No descriptions are made of the nematodes involved in their series of cases, but no mention is made of their having ruled out *Necator americanus* and/or *Ancylostoma duodenale* as the etiologic agent. Nor was mention made of the details of the stool examinations performed.

According to Belding (Textbook of Clinical Parasitology, New York, D. Appleton-Century Company, 1942, p. 292) "ground itch or hookworm dermatitis caused by the [hookworm] larvae in the skin is most prevalent . . . in the spring and summer months in the Southern United States." It is also well known that the latter nematodes pass through the pulmonary alveoli in the course of their intrahuman development and migration. Hence it appears that it has not been proved that the cases reported by Wright and Gold were not merely cases of hookworm.

NATHANIEL S. LEHRMAN, Albany, N. Y.

[NOTE.—The letter of Mr. Lehrman (a fourth year medical student at the Albany Medical College) was sent to Dr. Wright, who replies:]

To the Editor:—The elimination of the possibility of concomitant infection with *Necator americanus* must be based on two factors: (a) the clinical appearance of the skin lesions and (b) the absence of ova or parasites in the stool six weeks or more after the cutaneous invasion.

Further perusal of Belding's textbook (pages 492-496) clearly differentiates the papulovesicular eruption caused by *Necator americanus* and less frequently by *Ancylostoma duodenale* from the classic serpigenous burrows of creeping eruption of *Ancylostoma braziliense*. The mild, transient vesicular lesions produced by *Ancylostoma caninum* are similarly differentiated.

If concomitant infection with human hookworm had been present the ova and/or parasites would have appeared in the stool beginning six weeks after the cutaneous invasion. In our original paper (Wright, D. O., and Gold, Edwin M.: Loeffler's Syndrome Associated with Creeping Eruption [Cutaneous Helminthiasis], THE JOURNAL, August 11, p. 1082) we stated that "examination of 81 stool specimens from the 26 patients encompassing periods of observation of ten days to three months failed to reveal presence of ova or parasites in any specimen." In a paper in preparation at the present time we state that "a total of 441 stool examinations have been done on 76 patients with creeping eruption. Nematodal ova or parasites were not found except in 1 case that harbored *N. americanus* ova but this case did not develop pulmonary infiltration. Two hundred and four of these examinations were performed on 26 patients with Loeffler's pneumonia. Thirteen of these cases with pulmonary lesions had a total of 172 stool examinations over a period of more than six weeks."

Faust's zinc sulfate flotation technic was used in all stool examinations.

D. O. WRIGHT, Lieutenant Colonel, M. C., A. U. S.
Chief, Medical Service.

Bureau of Legal Medicine
and Legislation

MEDICOLEGAL ABSTRACTS

Medical Societies: Right of State Association to Order County Societies to Admit Applicants to Membership.—The Medical Association of the State of Alabama was incorporated by a legislative act in 1850, which has been amended and codified from time to time. Among other things the special act, as amended and codified, constitutes the association the board of health of the state, and the county medical societies, in affiliation with the state association and organized in accordance with the provisions of its constitution, are constituted boards of health for their respective counties under the general direction of the state board of health. Related legislation vests in these boards of health the sole and exclusive control of the public health and interdicts the setting up of any rival boards of health or executive bodies for the exercise of public health functions. By other legislation the board of censors of the state association is constituted the state board of medical examiners. By the constitution of the state association all members of county medical societies holding charters from the association are *ipso facto* members of the association. Article XV, section 2, of that constitution provides that graduates of reputable medical colleges "shall under such terms as may be prescribed by the association be eligible for membership in county medical societies." By section 3, *ibid.*, county societies, subject to the approval of the association, are authorized to adopt rules and regulations for their government. Section 4, *ibid.*, authorizes county societies "under the general control and supervision of the association" to exercise such jurisdiction over their members as is authorized by their respective constitutions. Section 14, *ibid.*, provides that county societies in affiliation with the association shall abide by all decisions of the association. Finally, for purposes germane to this abstract, article XX, section 3, provides that "the association shall have the right to confirm or amend in such way as it deems proper any verdict rendered, or conclusion reached, by a county society, the decision of the association being final."

After the inception of World War II several members of the Medical Society of Mobile County, a chartered county society of the state association, agreed among themselves to reject all applicants for membership, regardless of eligibility, pending the duration of the war. Drs. Webb and Greene, who in the words of the opinion in the present case "were worthy and reputable practicing physicians of Mobile County and possessed of all the qualifications for membership in the society . . . and . . . conceded to be eminently eligible for membership," applied for membership in the Mobile society and were rejected by reason of the agreement referred to. Just what transpired procedurally thereafter is not made clear in the reported case, but eventually the state association, on notice to all parties concerned, reviewed the action of the Mobile society in rejecting their applications for membership and determined as to each applicant "that there had been no charges filed or evidence presented against (them) and no constitutional, professional, ethical, or moral reasons offered to sustain" the act of the Mobile society in refusing to admit them to membership. The state association, after recommendation of its board of censors, by unanimous vote ordered and directed the county society to enroll Drs. Webb and Greene as members of the Mobile society. Thereafter Walker, a member in good standing of the Mobile society, instituted action against the Mobile society and its secretary to restrain the society from enrolling Drs. Webb and Greene as members of the society. The trial court dismissed the action, and Walker appealed eventually to the Supreme Court of Alabama.

Walker contended that the Mobile society was invested with the sole, exclusive, autocratic and irremediable right and authority to exclude from membership any physician, whether eligible or not, whatever the basis of such denial of membership, and the state association was without authority or jurisdiction to control the county society's action in this respect.

The Medical Society of Mobile County, answered the court, holding its charter from the Medical Association of the State of Alabama and acting in affiliation with it, is subordinate and subject to the supervisory powers of the association. The Mobile society and Walker as a member thereof were thereby subject and amenable to the provisions of the constitution and by-laws of the state association. A reasonable construction of the constitution of the state association, when considered in the light of the purposes the whole structure was designed to effect, makes it clear that the state association duly acted within the scope of its supervisory jurisdiction over the county medical society in ordering the enrolment as members of the two eligible physicians excluded. By the integrated structure of the two organizations the county society was "under the general control and supervision of the association" in regard to such matters (Constitution of State Association, article XV, section 4) and must "abide-by all decisions (constitutional) of the association . . . settled by the association" (*ibid.*, article XV, section 14) which decisions shall be final (*ibid.*, article XX, section 3). To permit the perpetuation of the agreement among some of the members of the Mobile society not to admit to membership any applicants during the pendency of the war could finally paralyze the effectiveness of the local society and if transacted long enough might result in the restriction of membership in the local society to those members party to the agreement and would thereby repose in them unintended and autocratic authority. Undoubtedly the constitutions of the state association and the county society, fairly interpreted, intend no such objectives, nor that the state association should be powerless to redress such action. However worthy the motives of the county society members in voting in accordance with their agreement, it was within the competence of the state association on a question of such fundamental policy, in the words of article XX, section 3, of the state association's constitution, to "amend . . . the conclusion reached by the county society, the decision of the association being final."

It is important to note, continued the court, that, by the law constituting the state association as the state board of health, it has become the residuum of official power and is impressed with attributes and functions of a highly public nature. To it have been delegated specific governmental prerogatives and duties by the state, repositing with it of exclusive franchises and powers of an eminent degree and of the highest concern to the public welfare. A similar status prevails as to the county medical society which is the county board of health. The state association and the county societies in affiliation with it have accepted these delegated responsibilities and it is plain that the parent organization, entrusted with such grave public duties, should not be powerless to direct and control action of a subordinate county society in matters of the character now under consideration, which must undoubtedly have a direct effect on the public welfare. There appears to be a certain opprobrium on any physician who is not a member of his county society and of the state association. Among other things, he cannot in this state become a health officer, since the selection of such an officer must be made from the membership of the society. The reasonable effect of thus excluding all eligible, incoming physicians from society membership would be to make them outcasts of the organization, to become members of which all eligible and worthy physicians naturally aspire. It would be sophistical to contend that this result would not strongly tend to discourage the best and most skillful members of the medical profession from locating in Mobile County and that this would not have a direct and deleterious effect on the public health of the county where there is necessarily a need for such physicians, owing to the exceptionally patriotic conduct of a large number of the local practitioners who entered the armed services, thereby resulting in a shortage of civilian physicians. It is manifest that the constitution of the state association, integrated as it is with the public health laws of the state, did not, nor does it, intend that the association should be impotent to correct such action in the discharge of its accepted duties and responsibilities of guarding the public health. On the contrary, it is clear that the constitution of the state association vests in the parent body superior authority and exclusive jurisdiction in matters such as here considered and to fail to give effect to the various provisions indicative thereof, so often repeated

throughout the body of the constitution, would be to ascribe to them no more than a meaningless tautology, evidently not intended. The construction placed on these constitutional provisions is entirely reasonable and consistent with the integrated structure of the medical bodies involved, and the rule seems to be established that the courts will not review the correctness of the interpretation placed on the constitution and by-laws of a voluntary association by its duly authorized tribunal in matters merely procedural or jurisdictional, if such interpretation is fair and reasonable. *Harris v. Missouri Pac. Ry. Co.*, D. C., 1 F. Supp. 946; *Pratt v. Amalgamated Ass'n*, etc., 50 Utah 472, 167 P. 830; *Long v. B. & O. Ry. Co.*, 155 Md. 265, 141 A. 504; *Simpson v. Grand Internat. B. of L. Engineers*, 83 W. Va. 355, 98 S. E. 580.

The court accordingly upheld the right of the state association to order the Mobile society to enroll Drs. Webb and Greene as members of the society and therefore affirmed the action of the trial court in dismissing Walker's bill to restrain that enrolment.—*Walker v. Medical Society of Mobile County*, 22 So. (2d) 715 (Ala., 1945).

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

NATIONAL BOARD OF MEDICAL EXAMINERS EXAMINING BOARDS IN SPECIALTIES

Examinations of the National Board of Medical Examiners and Examining Boards in Specialties were published in *THE JOURNAL*, Sept. 29, page 378.

BOARDS OF MEDICAL EXAMINERS

- ALABAMA: Mar. 19-21. Sec. Dr. B. F. Austin, 519 Dexter Ave., Montgomery 4.
ARKANSAS: * *Eclectic*. Little Rock, Nov. 8. Sec., Dr. C. H. Young, 1415 Main St., Little Rock.
CALIFORNIA: Oral. San Francisco, Nov. 11. *H'titten*. Sacramento, Oct. 15-18. Sec., Dr. Frederick N. Scatenen, 1020 N St., Sacramento 14.
CONNECTICUT: * *Medical Examination*. Hartford, Nov. 13-14. Nov. 27. Sec. to the Board, Dr. Creighton New Haven. *Homoeopathic*. Derby, Nov. 13-14. 1488 Chapel St., New Haven.
FLORIDA: * Jacksonville, Nov. 26-27. Sec., Dr. Harold D. VanSchaick, 2736 S. W. Seventh Ave., Miami 36.
IDAHO: Boise, Jan. 15. Dir., Bureau of Occupational Licenses, Miss Agnes Barnhart, 355 State Capitol Bldg., Boise.
ILLINOIS: Chicago, Oct. 9-11. Supt. of Registration, Department of Registration & Education, Mr. Philip Harman, Springfield.
KANSAS: Topeka, Dec. 6. Sec., Board of Medical Registration and Examination, Dr. J. F. Fressig, 905 N. Seventh St., Kansas City 10.
MAINE: Portland, Nov. 13-14. Sec., Board of Registration of Medicine, Dr. A. P. Leighton, 192 State St., Portland.
MARYLAND: *Medical*. Baltimore, Dec. 11-15. Sec., Dr. J. T. O'Mara, 1215 Cathedral St., Baltimore. *Homoeopathic*. Baltimore, Dec. 11-12. Sec., Dr. J. A. Evans, 612 W. 40th St., Baltimore.
MASSACHUSETTS: Boston, Nov. 20-23. Sec., Board of Registration in Medicine, Dr. H. Q. Gallupe, 413-F State House, Boston.
NEW JERSEY: Trenton, Oct. 16-17. Sec., Dr. E. S. Hallinger, 28 W. State St., Trenton.
NEW MEXICO: * Santa Fe, Oct. 8-9. Sec., Dr. LeGrand Ward, 141 Palace Ave., Santa Fe.
NORTH DAKOTA: Grand Forks, Jan. 1. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.
OHIO: *Endorsement*. Columbus, October. Sec., State Medical Board, Dr. H. M. Platter, 21 W. Broad St., Columbus.
OKLAHOMA: * Oklahoma City, March 23. Sec., Dr. J. D. Osborn Jr., Frederick.
OREGON: * *Reciprocity*. Portland, Oct. 19. Exec. Sec., Miss L. M. Conlee, 608 Failing Bldg., Portland 4.
SOUTH CAROLINA: Columbia, Nov. 13. Sec., Dr. N. B. Heyward, 1329 Blanding St., Columbia.
SOUTH DAKOTA: * Pierre, Jan. 15-16. Sec., Medical Licensure, State Board of Health, Dr. Gilbert Cottam, Capitol Bldg., Pierre.
VERMONT: Burlington, March or April 1946. Sec., Dr. F. J. Lawliss, Richford.
WISCONSIN: * Madison, Jan. 8-10. Sec., Dr. C. A. Dawson, Tremont Bldg., River Falls.

* Basic Science Certificate required.

BOARDS OF EXAMINERS IN THE BASIC SCIENCES

- CONNECTICUT: Oct. 13. Address State Board of Healing Arts, 250 Church St., New Haven 10.
DISTRICT OF COLUMBIA: Washington, Oct. 22-23. Sec., Commission on Licensure, Dr. G. C. Ruhland, 6150 E. Municipal Bldg., Washington.
FLORIDA: DeLand, Nov. 3. Sec., Dr. J. F. Conn, Box 655, DeLand.
IOWA: Des Moines Oct. 9. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, Capitol Bldg., Des Moines.
MICHIGAN: Ann Arbor and Detroit, Oct. 12-13. Sec., Miss Eloise LeBeau, 101 N. Walnut St., Lansing.
RHODE ISLAND: Providence, Nov. 14. Chief, Division of Examiners, Mr. Thomas B. Casey, 366 State Office Bldg., Providence.
SOUTH DAKOTA: December. Sec., Dr. J. D. Alway, Aberdeen.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Journal of Ophthalmology, Cincinnati

28:701-821 (July) 1945

- Evaluation of Visual Acuity Symbols. W. H. Fink.—p. 701.
Influence of Selected Spectral Distribution on Glare Effect, Studied by Means of Dark Adaptation. E. Simonson, S. Blankstein and E. J. Carey.—p. 712.
Binocular and Red-Free Ophthalmology. R. I. Lloyd.—p. 725.
Cause and Treatment of Poor Vision in Aniridia. L. G. Algers.—p. 730.
Aniseikonia and Spatial Orientation. H. M. Burian and K. N. Ogle.—p. 735.
Glaucoma and Essential Progressive Atrophy of Iris. H. S. Sugar.—p. 744.
Observations on Retinal Blood Flow with Aid of Kukán's Ophthalmodynamometer. M. W. Morgan Jr., J. B. Mohny and J. M. D. Olmsted.—p. 749.
Recurrent Juvenile Papilloma of Conjunctiva: Case Report. J. D. Walker.—p. 751.

Penicillin in Neurosyphilis.—During the past fourteen months the neurosyphilis service of the Boston Psychopathic Hospital has treated 140 cases of symptomatic neurosyphilis. The treatment consisted of one half the usually prescribed amount of fever therapy and penicillin, given concurrently or in succession. Sodium penicillin dissolved in saline solution was administered intramuscularly for a total dose of 3,000,000 Oxford units. According to Rose, penicillin is an active therapeutic agent in all forms of neurosyphilis but the degree of effectiveness has not been determined. The best results are

obtained in syphilitic meningitis. A small series of cases of primary optic atrophy have shown surprisingly good results. All forms of parenchymatous neurosyphilis apparently need fever therapy as well as penicillin. Penicillin is an agent which acts directly on the invading organisms and therefore can be useful only in cases in which there is evidence of spirochetal activity.

Journal of Lab. and Clinical Medicine, St. Louis

30:559-638 (July) 1945

- *Immunologic Studies in Patients with Subacute Bacterial Endocarditis Treated by Combined Penicillin-Heparin Method: I. Sensitivity to Penicillin. M. Grohnick and L. Loewe.—p. 559.
Effect of Artificially Induced Fever on Humoral Antibodies and on Histamine Intoxication in Guinea Pig. R. Y. Gottschall, D. Laurent and P. DeKruif, in Collaboration with W. M. Simpson, H. W. Kendall and D. L. Rose.—p. 563.
*Studies on Rickettsial Agglutination in Typhus. F. K. Fitzpatrick.—p. 577.
Behavior of Blood Cholesterol in Thyrotoxic Patients Under Treatment with Thiouracil. T. H. McGavack and I. J. Dreker.—p. 586.
Note on In Vitro Respiration of Muscle in Myasthenia Gravis. F. J. Stare and H. T. Ricketts.—p. 589.
Effect of Insulin on In Vitro Respiration of Human Skeletal Muscle. H. T. Ricketts and F. J. Stare.—p. 594.
Effect of Ultraviolet Irradiation on Blood Hemoglobin. A. P. Barer and W. M. Fowler.—p. 600.
Effect of Digitalis, Epinephrine and Surgery on Response to Heparin. C. Moses.—p. 603.

Subacute Bacterial Endocarditis.—Twenty-seven patients receiving intensive and prolonged treatment with penicillin failed to develop any positive skin or ophthalmic reactions to a solution of penicillin containing 10,000 units per cubic centimeter. They did not develop positive skin reactions to the source of this product, the mold *Penicillium notatum*. The dosage of penicillin had been high, treatment had been given over long periods of time, and in nearly one half of the patients therapy had been administered in interrupted courses. These circumstances would ordinarily favor active sensitization to the drug employed if a potent antigenic substance was involved. The results indicate that penicillin is not a potent antigenic product. The most striking data concern a man who had received six courses of therapy over a total period of 230 days, of which 185 were actual treatment days. The courses ran from 12 to 52 days, the free intervals from 2 to 13 days. The smallest dose in any one course was 2,700,000 units and the largest was 44,500,000 units. The total dose given during the entire period of treatment was 112,620,000 Oxford units. The patient did not develop sensitivity to penicillin nor did he show positive skin reactions to penicillin.

Rickettsial Agglutination in Typhus.—Fitzpatrick's report deals with the results of agglutination tests obtained over a period of years with a variety of serums from man and animals infected with or vaccinated against typhus, with the cross-agglutinations encountered and with serum absorption experiments. Some of the agglutinations were performed with the tissue culture antigen, but for the most part the antigens used were prepared from the yolk sacs of infected eggs. For the agglutination test, glass slides having twelve depressions were used. The serum to be tested was set up in tubes in doubling dilutions, and one drop of each dilution was transferred to the slide with a capillary pipet. An equal volume of antigen was added. The slides were then rotated by hand to secure thorough mixing and placed on moist paper in Petri dishes in the incubator at a temperature of 40 C. For uniform results the slides were left in the incubator for five hours. They were then placed in the ice box overnight, after which a final reading was made with the low power objective of an ordinary microscope. With serums which show a titer of 1:80 or above, agglutination in the lower dilutions is visible to the unaided eye after incubation for from thirty to sixty minutes and in much less time if the rotation of the slide is carried out for two minutes. When the test is being used for diagnostic purposes this rapid agglutination is of practical importance. The microscopic agglutination test as used was found to be an easy and convenient means for the diagnosis of typhus in human serums and proved to be a useful tool for the study of agglutinin development in man and animals following infection or vaccination. The observations of Castañeda on the removal

of heterologous typhus agglutinins were confirmed. Serums from rabbits infected with spotted fever did not agglutinate either of the typhus antigens. Serums obtained from cases of endemic typhus were found not to agglutinate spotted fever antigen.

Intracranial Angiography.—Blood vessels momentarily rendered densely opaque serve as reference points in detecting disturbances of anatomic relationships produced by intracranial lesions. This method, useful when vascular displacement provides evidence of disease in neighboring tissues, is of special value when the vessels are involved directly. Intracranial angiography has been used systematically at the University Hospital of Ann Arbor since January 1941 in situations in which this method of study appeared to offer the likelihood of solving particularly difficult diagnostic problems. In three years 127 patients have been subjected to this type of examination. In the bulk of these the carotid system was injected; vertebral arteriography was used in only 6 instances. When the indications for its use are clear, intracranial angiography may be employed without danger to the patient if certain conditions are observed. There has been no fatality attributable to the procedure in the 127 cases which they have observed. It is inadvisable to inject any material into the circulation of the brain in cases of extreme arterial hypertension, far advanced arteriosclerosis, acute intracerebral or subarachnoid hemorrhage, recent thrombosis, or embolism of cerebral vessels. Even in the absence of such contraindications, one may occasionally encounter transient hemiparesis, hemiparesthesia, aphasia, convulsive manifestations or temporary accentuation of presenting neurologic signs. Such untoward effects occurred in less than 3 per cent of the patients examined by the authors, and in no instance did they persist. Similar symptoms are as common after pneumographic procedures. Actually angiography is better tolerated than ventriculography in certain cases of expanding lesions associated with high intracranial pressure, because intracranial hydrodynamics are not materially altered. Transcutaneous arterial injections,

advocated by some authors, do not appeal to List and his associates, who prefer the direct surgical approach, which eliminates the likelihood of extravascular leakage and inadvertent dislodgment of the needle with consequent danger of uncontrolled bleeding. Egas Moniz uses the simple surgical procedure of exposing the common carotid at the base of the neck. The authors feel that it is only slightly more difficult to prepare the internal carotid for injection and that this approach holds the total amount of contrast material needed at a minimum and obviates annoying shadows cast by branches of the external carotid. Despite its undesirable property of long half-life radioactivity, thorotrast in amounts not exceeding 25 to 30 cc. is the most satisfactory contrast material at present available for intracranial angiography.

Irradiation in Carcinoma of Prostate.—During the two year period ended in May 1943, 27 cases of carcinoma of the prostate were seen by Munger, 12 of which were treated by resection with regional and testicular irradiation, 8 by resection, irradiation and estrogen therapy, and 7 by orchiectomy. The most effective stabilization has occurred among those who were treated by resection, testicular and regional irradiation, and adjunct estrogen therapy coincident with the x-ray treatments. The development of carcinoma of the prostate is seemingly related to the gonadal and extragonadal depots of androgen production. Surgical castration relieves only the gonadal depots of hormonal production. Adequate testicular and regional irradiation definitely dissipates hormonal production. The female hormone depresses androgenic activity.

Penicillin in Acute Osteomyelitis.—Altemeier and Helmsworth treated 34 cases of acute osteomyelitis with penicillin. There were 25 cases of acute hematogenous osteomyelitis of the long bones, in some of which also the flat bones of the pelvis were involved. There were 3 cases of infection of the pelvic bones only, 5 of the facial and cranial bones, and 1 of the ribs. The ages of the patients showed the prevalence of the disease in the young. Nine of the patients were females and 25 were males, a fact emphasizing the higher incidence of the disease in the male. The etiologic agent was the hemolytic *Staphylococcus aureus* in 29 cases. Solutions of the sodium salt of penicillin in sterile isotonic solution of sodium chloride with a concentration of 5,000 units per cubic centimeter were used in all but 1 case, in which the calcium salt was employed. The solution was administered by continuous intravenous drip in 10 cases and by interval intravenous or intramuscular injection in the remainder. A dose of 1,500,000 or more units administered

over a period of two or more weeks is the effective dosage. If the diagnosis was made early and penicillin treatment instituted promptly without surgical drainage, both general and local infections were brought under control so thoroughly that a minimal amount of residual bony damage resulted. Moderate delay in diagnosis and treatment increased the extent of bony damage, but the infection was nevertheless quickly arrested without the aid of drainage and without sequestration. Small localized abscesses were treated satisfactorily by aspiration followed by injection of a solution of penicillin. Large abscesses were treated by prompt incision. Delay in diagnosis and treatment not only increased the degree of bony damage but favored the development of large abscesses, sequestrums and metastatic visceral infections. Penicillin is a powerful and effective chemotherapeutic agent in the treatment of acute osteomyelitis. When administered early and in adequate amounts, it reduces the mortality and morbidity, brings the infection under control, minimizes local destruction of bone and resultant deformities, permits spontaneous removal of necrosed bone and healing and makes possible early return of normal or nearly normal function.

Sucking Wounds of Chest.—During a three month period 70 patients with sucking wounds of the chest were treated in an evacuation hospital. In 49 instances the wounds were of the penetrating type; in 20 they were perforating through and through, and there was 1 gutter type of wound. Right sided wounds were nearly twice as common as left sided. Presumably left sided wounds were more frequently fatal on the battlefield. Slight to moderate dyspnea was present in two thirds of the patients, most of whom required oxygen. All patients with sucking wounds were treated in the shock ward, and oxygen therapy was started if necessary. Patients were left on the same litter until they arrived at the surgical ward and sometimes until they reached the postoperative ward. A transfusion of stored citrated blood was begun as soon as possible in those showing signs of shock and hemorrhage. When a patient was out of shock and was not uncomfortable out of oxygen, he was sent to have roentgenograms made. While sucking chest wounds had surgical priority, it was thought that once they had been sealed and shock overcome it was time well spent to let the circulatory and respiratory mechanisms adjust themselves. Three principal types of thoracic operation were performed: (1) wound débridement and closure of the chest opening, (2) thoracotomy and (3) thoracotomy plus transdiaphragmatic exploration of the upper abdomen. Six of the 70 patients died without surgical treatment. Postoperative treatment is directed toward the correction of circulatory and respiratory disturbances, reexpansion of the lung and prevention of infection. The overall mortality rate, 24 per cent, and the operative mortality rate, 17 per cent, were higher than those for other patients with penetrating and perforating wounds of the pleural cavity.

Veratrum Viride in Hypertensive Syndromes of Pregnancy.—Harkins reviews observations on 34 cases of severe preeclampsia and 14 cases of eclampsia. Evidence is presented that vasospasm of the terminal arterioles plays an important role in the pathogenesis of the disease. Emphasis is placed on veratrum viride as a vasodilator. Only one preeclamptic patient developed eclampsia under the described treatment. Rapid control of convulsions was accomplished by a combined therapeutic

regimen which included hypertonic glucose by vein, magnesium sulfate intramuscularly and veratrum viride hypodermically. Cesarean section was not deemed necessary in any of the preeclamptic or eclamptic patients. There were no stillborn infants among the preeclamptic patients and only 1 among the eclamptic. The use of veratrum viride in some of the other hypertensive syndromes of pregnancy is believed to be of value and is under further investigation. A series of 11 such cases is presented. Veratrum viride, in the form of a purified aqueous solution of the active alkaloid, can be given in therapeutic doses without signs of drug intoxication, without producing vascular collapse and without the need of antidotes.

New Form of Goiter.—Simard presents the case of a girl aged 11 who since birth had presented a swelling in the front of the neck. At the time of clinical examination in August 1944 the thyroid was about five times the normal size. The metabolism was normal to plus 3. A thyroidectomy in September 1944 revealed that the left lobe was the size of a fist and the right about four times the normal size. The entire thyroid gave the impression of fatty infiltration. Large stumps of the thyroid were left in place because of fear of postoperative myxedema. The child was in good health several months after the operation. Macroscopically the removed specimen did not resemble thyroid tissue; it was soft and pale yellow. With slight magnification it was impossible to distinguish thyroid tissue; the gland was transformed into fat tissue divided by numerous connective tissue walls which contained lymphoid islands with clear centers. Strong magnification revealed the structure of the thyroid gland but probably reduced to its most simple form. Small thyroid vesicles appeared in the connective tissue walls or in the lymphoid infiltrations. The connective tissue was abundant particularly in the peripheral parts of the gland, where it formed sclerous regions in which a few glandular vesicles persisted. In a subcapsular region the author found a small adenoma the size of a pea. He suggests that other adenomas might exist in parts he could not examine and that their presence explains the absence of thyroid insufficiency. The lesions can be designated as thyroidal sclerolympholipomatosis. This is not a case of Riedel's ligneous thyroiditis. It slightly resembles Hashimoto's goiter, but this occurs almost exclusively in women around 50, whereas the lesion in question began during intrauterine life. The author thinks that it is a congenital malformation associated with disease of the adipose tissue, for not only is the thyroid infiltrated with fat tissue but multiple lipomas have been found on the neck and another one is beginning in the left axilla.

Absorption of Penicillin from Body Cavities.—Florey and Heatley report studies that were carried out to ascertain whether a suitable dose of penicillin injected into serous or abscess cavities would not only act locally but produce a prolonged and effective level of the drug in the blood stream. The route in most cases investigated has been the pleural cavity, but penicillin has also been given via the knee joint, intrathecal space and abscess cavities. A single injection following aspiration, at the rate of 120,000 units in twenty-four hours, has been given to adults. For children up to 8 years 1,000 units per pound of body weight in twenty-four hours was used—an amount which, given in divided doses by the intramuscular route, has been generally found adequate to maintain bacteriostasis. The presence of a bacteriostatic concentration in the blood stream (or "serum inhibition") was tested for by the drop-on-slide method. Injection of 120,000 units of penicillin into a pleural cavity, after aspiration of an effusion, ensured a bacteriostatic concentration of the drug in the blood stream for twenty-four hours or more; 240,000 units produced a similar effect for about forty-eight hours. Injection of 120,000 units into 2 intact but infected knee joints produced the same effect for at least thirteen hours in 1 case and twenty-four hours in the other. Injection of 120,000 units in 2 adults, and its equivalent in an infant, into the intrathecal space produced the same effect for about fifteen hours. The protracted systemic effect, due to slow absorption does not appear to be an exclusive property of serous membranes but is associated also with cavities in the body not lined with such membranes, such as abscess cavities. Clinical application of these findings has already given good results in (a) the prophylaxis of postpneumonecctomy infection and (b) the treatment of pneumonia, pyemia, osteomyelitis, and streptococcal arthritis when accompanied by pleural or synovial effusion.

Sulfadiazine Dysuria.—During the treatment of some 450 penetrating head wounds with sulfadiazine, Jepson and Whitty had an opportunity to study the dysurias occurring with this drug. After an initial 3 Gm. intravenously, 3 Gm. was given by mouth four-hourly for forty-eight hours, then six-hourly for a further forty-eight hours. In the first 40 cases so treated 20 grains (1.3 Gm.) of sodium bicarbonate and the same amount of sodium citrate were given with each dose of sulfadiazine. No special attention was paid to fluid intake apart from maintaining an average daily intake of about 8 pints (3,840 cc.). In this series there were 6 cases (15 per cent) of poisoning. This comparatively high incidence caused the authors to review the alkali and fluid intake, and thereafter, in a further series of 410 cases, with each dose of sulfadiazine, 40 grains (2.6 Gm.) of sodium bicarbonate and 30 grains (2 Gm.) of sodium citrate were given and a total fluid intake of 10 pints (4,800 cc.) in twenty-four hours was aimed at. In this series 11, or 2.5 per cent, of patients developed dysuria; that is, there was a total of 17 cases of dysuria among 450 patients with head wounds. The incidence bears a close relation to urinary pH ; no case occurred with a pH of over 6.5. No sulfadiazine deposit was

found in any urine examined with a pH of over 7.5. Neither dosage nor length of administration appears to affect the incidence. Intense abdominal pain with loin tenderness, oliguria and blood stained urine are the presenting symptoms. Prophylaxis depends on the control of urinary pH and output. Treatment is by intensive intravenous fluids with alkalis. In only 5 cases was ureteral catheterization done, and it was probably necessary in only 2. None of these cases were fatal.

*First Results of Obligatory Antidiphtheric Antitetanic Vaccination in Children: Diphtheria Becomes a Disease of Adults, R. Poulain.—p. 70.

Antitetanic Serotoxoid Therapy in Manifest Tetanus.—Ramon and his associates state that the idea of utilizing toxoids not only for the prevention but also for the treatment of toxic infections was first realized by the employment of staphylococcal toxoid in the treatment of various staphylococcal disorders. In an infection like tetanus with its usually rapid evolution the use of toxoid with its relatively slow action involves the risk that the patient may succumb before deriving benefit from the toxoid. Thus the injection of antitetanic serum remains the first and most urgent measure in manifest tetanus. The antitoxin immediately furnishes the means to fight the invading intoxication. Toxoid therapy added to serotherapy will complete the effects of the serotherapy. Numerous experimental studies and trials on human subjects permit the formulation of therapy of developing tetanus consisting in simultaneous injections of a massive dose of antitetanic serum and of a convenient quantity of tetanic toxoid, the latter being renewed several times at four or five day intervals. The early injection of a massive dose of antitetanic serum furnishes at once the quantity of antitoxin necessary for the neutralization of the toxin already in circulation or which the organism continues to elaborate. This method dispenses with the daily serum injections. The toxoid complements the action of the serum in the course of tetanus, and the combination of serum and toxoid insures the stability and permanence of the antitetanic immunity and protects the cured subject against new attacks of tetanus.

Results of Obligatory Antidiphtheric-Antitetanic Vaccination.—Poulain reports a severe epidemic of diphtheria in Lyons during the year 1943 following an increase observed in 1942. It involved the adult population, among whom the percentage of the vaccinated was very small and children up to 3 years of age before their vaccination. The antidiphtheric antitetanic vaccination with the mixed toxoid of Ramon mitigated this outbreak in children of all ages in proportion to the number that had been vaccinated. Vaccination has prevented numerous cases of diphtheria among children, who are more susceptible than adults to epidemic outbreaks of diphtheria. It can be affirmed that when all children are correctly vaccinated diphtheric morbidity will become small and the mortality zero for the population of children. Vaccination will probably become necessary for adults up to the age of 30, since the diphtheric morbidity is considerable and the mortality far from negligible for this part of the population. It might be advisable to make obligatory a renewed vaccine injection at the age of 15 years on leaving school.

Book Notices

Preventive Medicine. By Mark F. Boyd, M.D., M.S., C.P.H., Field Staff Member, International Health Division, Rockefeller Foundation. Seventh edition. Cloth. Price, \$5.50. Pp. 591, with 187 illustrations. Philadelphia & London: W. B. Saunders Company, 1945.

As a convenient guide and reference book for teachers of undergraduate medical students in the required course in preventive medicine in the second or third year, this well tested book has a respected and commendable place, as will be acknowledged in greeting this edition. In the process of simplifying the subject and abbreviating the text for the purpose, the author's classification of the preventable diseases lacks desirable distinctions and some major categories. Habit forming drugs such as alcohol, tobacco and those of the morphine and cocaine series might better be separately dealt with and not, as is alcohol, under diseases due to dietary deficiencies. Cancer, so far as preventable, would seem to justify at least a mention and preferably a chapter to itself. There are preventable aspects of mental diseases other than those related to nutritional defects which would seem to claim attention. The allergies are not dealt with, as they might well be, from the environmental and hereditary points of view as preventable conditions of ill health.

Of the thirty-seven chapters, the second to the twenty-third inclusive, which deal with the communicable diseases, are much the most satisfactory and authoritative. Those on heredity and disease (29), the hygiene of infancy and childhood (30 and 31), air heating and ventilation (32) and certain aspects of personal hygiene (33) are not of as high a quality. The 10 pages out of 560 which are devoted in chapter 37 to public health offer but a sketch which will add little to the general information of the medical student.

With such books as those of Rosenau, Mustard and Smillie widely used for students of medicine and public health, the role of the condensed and simplified textbook is less important than it was twenty-five years ago.

The chapters are of good class-session length. The bibliography (pp. 560-566) is good in selection and length. The index is entirely adequate.

The author appears to have a low regard for physicians and their part in initiating, promoting and cooperating in measures of preventive medicine, as expressed in the foreword and elsewhere. The reviewer considers this unfortunate and not consistent with the facts of experience in the United States of America over the past quarter century. An alternative for the foreword is herewith offered as expressing more nearly the truth of the situation: The medical profession does and will always play the leading role in preventive medicine and public health, chiefly in private practice and necessarily in public service. Physicians are making increasing use of their opportunities and the public interest in preventive medicine. There continues to be the heartiest and practically unanimous cooperation between the medical profession and the public health authorities, and thus the students of today should understand and take part in.

Pharmacology and Dental Therapeutics: A Textbook for Students and Practitioners. By Hermann Prinz, A.M., D.D.S., M.D., and U. Garfield Rickert, A.M., D.D.S. Ninth edition by Edward C. Dobbs, D.D.S., Associate Professor of Pharmacology, Dental School, University of Maryland, Baltimore. Cloth. Price, \$6.50. Pp. 567, with 35 illustrations. St. Louis: C. V. Mosby Company, 1945.

The rearranged contents and standardized names and dosages acceptable to both the American Dental Association and the American Medical Association will keep practitioners abreast of the current knowledge of drugs and their usage. The section devoted to dental therapeutics will be most valuable to the dental practitioner. The authors' advocacy of caution in the use of sulfonamide drugs and of penicillin is supported by the findings of Drs. Canfield, Everett and Ferguson. The authors also point out the fact that relationship between phosphorus metabolism and dental caries and periodontoclasia has not been established and that the direct action of vitamins in the animal body is not thoroughly understood. The numerous prescriptions given are of considerable value to dental practitioners and will enable them to discontinue the use of proprietary drugs, which are usually excessively priced. The book is well got up. The paper is excellent, the type large and clear.

Non-Penetrating Injuries of the Heart. By G. J. C. Brittain, M.B., Ch.B. A Thesis Accepted for the Degree of M.D. (Liverpool). Paper. Pp. 77, with 47 illustrations. Derby, England: The Author, [n. d.].

As the author states in his introduction, there is little or nothing to be found in the average textbook with regard to the subject of nonpenetrating injuries to the heart, but this is largely "owing to the fact that until quite recently the existence of the condition has been looked upon with considerable skepticism." Much of this skepticism has been fostered by the not very critical reports of such injuries. In addition to this, in many cases in which there are so often doubtful objective findings or findings not definitely correlated with the injury, physicians have been inclined to feel that the possibilities of compensation were a more potent etiologic factor than the injury itself.

This short but comprehensive study is important in redirecting the attention of the physician to this type of injury, its diagnosis and its importance. We are prone to forget how elastic the thoracic cage is and that the sternum can be pushed back by a sudden blow or a blast injury far enough to contuse the heart, without any evidence of external injury and without any fracture of ribs or sternum.

In this small volume the author gives a comprehensive review of the problem and of the history, the signs and symptoms arising from the condition, followed by reports of 18 cases. A complete bibliography adds to the value of this contribution to a subject too often disregarded.

Textbook of Neuropathology. By Arthur Weil, M.D., Associate Professor of Neuropathology, Northwestern University Medical School, Chicago. Second edition. Cloth. Price, \$5.50. Pp. 336, with 287 illustrations. New York: Grune & Stratton, 1945.

Separate departments of neuropathology have been established in many medical schools and hospitals in this country in the last twenty years. As a result new material has accumulated, now finding its way into textbooks. Prior to 1933, when Dr. Weil published the first edition of this book, there was only one other book in English, except for the translations of German textbooks. Since 1933 at least four new monographs have appeared on the same subject and a journal has been established in this country giving stimulus and encouragement to research. As a reflection of this activity, Dr. Weil has issued a second edition of his well established book, twelve years after the first. In it he has incorporated the advances in neuropathology during the intervening years and corrected minor errors appearing in the first edition. The present volume furnishes a compact, clearly written account of the subject meeting the essentials needed of a student of medicine or a beginner in a laboratory of pathology. The text is authoritative. References are satisfactory and the illustrations were chosen with discrimination. There is a brief section on staining technic.

Galen on Medical Experience. By R. Walzer. First edition of the Arabic version with English translation and notes. Published for the trustees of the late Sir Henry Wellcome. Cloth. Price, \$4. Pp. 164. New York, London & Toronto: Oxford University Press, 1944.

This offers to the student of medical history an opportunity of becoming acquainted with a work which was once considered lost. It is important for knowledge of the empirical school, and it presents a survey of the philosophical conceptions of Galen's time. The Arabic manuscript from which the translation was done is the only one in which this work is complete. The Arabic translation, done by Hubaish ibn al-Hasan al-A'sam, is of an exceptionally high standard. The authenticity of the treatise is assured by many important facts which are referred in the preface. It is interesting to note that this treatise was intended to reproduce a disputation between Pelops, a physician belonging to the dogmatic school, and the empiricist Philippos. Galen affirmed definitely his opposition to the physician Asclepiades and sustains convincingly the necessity of the close union of empiricism and theory. The English translation is excellent and makes the book very readable. The notes and bibliography give those who are not familiar with the medicine of the empire the possibility of easy orientation. For all who have an interest in the problems of experimental medicine, which were so vivaciously discussed in antiquity, this book is a precious mine of information. To all physicians who like to be informed about an important phase in the development of medicine it is a valuable source of consultation.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ANTICOAGULANT SOLUTION FOR BLOOD PRESERVATION

To the Editor:—I understand that the army blood procurement stations use an anticoagulant solution for whole blood which keeps blood suitable for use as whole blood for as long as one month. Can you supply me with the composition of this anticoagulant and preservative? M.D., Tennessee.

ANSWER.—The diluting fluid adopted during the latter part of the war for the preservation of whole blood collected by the American Red Cross for use overseas by the Army and Navy consists of 1.33 per cent trisodium citrate ($2H_2O$), 0.47 per cent citric acid and 3.0 per cent dextrose. It is used in the proportion one part of diluent to four parts of blood, i. e. 125 cc. of fluid for 500 cc. of blood. With continuous refrigeration at 4 to 10 C., the preservation of whole blood thus diluted is generally satisfactory for about thirty days, but there is some variability in the state of preservation of individual bloods at the end of that time. In practice, the dating period has been held at twenty-one days. This solution has been called ACD (acid-citrate-dextrose) by American investigators. It is essentially the same as that recommended by Loutit, Mollison and Young (*Quart. J. Exper. Physiol.* 32:183 [Dec.] 1943).

REFRACTORY PROSTATITIS

To the Editor:—I have had pus (*Bacillus pyocyaneus*) in the prostate for the past twelve years and have tried almost everything—massage, diathermy, intravenous injection of sodium iodide, autogenous vaccines, ultraviolet rays. Is sulfathiazole of value? What treatment is advised? I am 70 years of age.

M.D., Florida.

ANSWER.—It is possible that pus in the prostate gland may be associated with an enlargement of the prostate and an abnormal amount of residual urine. If so, the proper approach to the problem would be to remove the obstruction. If, on the other hand, there is only a prostatitis without any associated pathologic change, no form of treatment can be suggested that is better than prostatic massages. Clinical experience in the use of the sulfonamides and also penicillin has been disappointing in the treatment of chronic prostatitis even when the bacteria causing the infection are supposed to respond to these agents. It would seem that thorough urologic examination should be made if this has not already been done.

ETIOLOGY OF ULCERATIVE COLITIS

To the Editor:—What is the latest opinion on Barga's bacilli as to pathogenicity? Has succinylsulfathiazole been effective, and if so in what dose and for how long?

D. Guilford Dudley, M.D., Endicott, N. Y.

ANSWER.—Barga in his latest book on chronic ulcerative colitis and its modern management again emphasizes the pathogenic role of streptococci. Other investigators, however, do not consider this as established. Modern studies on the action of sulfonamides on the gastrointestinal flora have shown a change from a predominance of gram negative to gram positive organisms without modification of the clinical course. The relative as well as absolute increase in the gram positive flora without deterioration in the clinical condition of the patient may be considered as evidence against the specific pathogenicity of these cocci. The etiology of chronic nonspecific ulcerative colitis still remains obscure.

CHRONIC PROSTATITIS

To the Editor:—I would appreciate any data on the use of penicillin sodium in the treatment of old gonorrhea with chronic prostatitis and posterior urethritis. Is it known to give clinical cure in cases of fifteen to twenty years' duration with the characteristic "gleet"? M.D., Ohio.

ANSWER.—Such a lesion should not be called an old gonococcal condition because it no longer has gonococci but long since has been secondarily infected and has innumerable kinds of secondary invaders, some of which are affected by the use of penicillin but many others do not respond to this medication. It would not be considered good practice to treat such infections by the use of penicillin alone and there is no substitute for local treatment such as massage and dilation for this type of lesion. It is the consensus that penicillin in any amount does not materially add to the effectiveness of standard management.

FINGER PRINTING OF CADAVERS

To the Editor:—What is the best method of restoring fingers to normal contour for finger printing for purposes of identification? I refer particularly to cases in which death has taken place some time previously and also to postmortem shrinkages following drowning and submersion.

Robert K. Wilson, M.D., Montgomery, Ala.

ANSWER.—If decomposition has not set in and the fingers are pliable, it is sometimes possible by use of a needle syringe to inject either water or glycerin into the tips of the fingers. When this method is followed a piece of cord should be tied securely around the finger immediately below the pattern area before injecting the fluid. The finger is then ready for printing. When the patterns of the fingers are discernible they may be photographed as they are, but in the event that the skin is in an advanced state of decomposition or if there has been a hardening of the skin photography is the only resort. However, when conditions permit, the skin may be carefully removed from each finger and the underside of the pattern areas scraped until the skin is transparent. It should then be placed in a glass frame and photographed, employing an arrangement of transmitted or reflected light. Under the latter circumstances the photographic method alone is employed and there should be no attempt to obtain fingerprint impressions by the inking process.

CRUSHING THE PHRENIC NERVE

To the Editor:—Is there any procedure by means of which one may control the duration of paralysis of the phrenic nerve in the treatment of pulmonary tuberculosis?

Major, M. C., A. U. S.

ANSWER.—A thorough crushing of the main phrenic nerve trunk in only one place with the Haight phrenic crusher or with the tip of a mosquito hemostat, together with the resection of absolutely all small accessory phrenic nerve roots, produces hemidiaphragmatic paralysis of approximately six months' duration (reduced in short persons and longer in tall ones). If all accessory roots are not interrupted, a variable and unpredictable amount of diaphragmatic movement may persist after the operation or occur within a few days to several months following a period of complete paralysis. If the main phrenic nerve trunk is not thoroughly crushed, paralysis may be incomplete, or complete and brief. If the main trunk is broadly and thoroughly crushed, or crushed in several places, permanent diaphragmatic paralysis may result, or paralysis may persist for many months. As there is no known method (except by local anesthesia) for producing certain complete paralysis that does not completely destroy the axons at the site of operation, the duration of diaphragmatic paralysis necessarily depends on the rate of regrowth of axons from the nearest ganglion cells to the diaphragm. If the means used to destroy the axons resulted in only a narrow area of scar tissue, the new axons can freely pass this barrier, growing at approximately the rate of 1 mm. per diem. If, however, a broad area of crushing or an injected chemical produces a broad area of scar, the new axons may either fail to pass through this barrier or may do so after a variable period of delay, and then only some of the axons may succeed in passing the barrier, with resulting incomplete return of diaphragmatic function.

CONTRACEPTIVES, TAMPONS AND ENDOMETRIOSIS

To the Editor:—An article in *The Journal* June 9, 1945 states that "dysmenorrhea, . . . which is seen in women in the upper walks of life who have used contraceptives and vaginal tampons, is usually due to endometriosis." One infers that there may be a causal relationship. Is not endometriosis usually the result of transubal transplantation of particles of endometrium, and may it not be, at least in an occasional case, the result of such retrograde forces as may arise in the Rubin test or in the use of uterine dilators? The makers of vaginal tampons state that they cause no blockage of flow; how then may these devices be implicated in endometriosis? Can one safely advise their use? How could contraceptives, which of course are not used during menstruation, be to blame?

M.D., Colorado.

ANSWER.—It has not been proved that endometriosis has ever resulted from the use of contraceptives or vaginal tampons. It is hard to conceive that any device used in the vagina for contraceptive purposes such as a rubber diaphragm or jelly could block the external os sufficiently to force blood back through the oviducts into the peritoneal cavity. Likewise, the flow of blood from the cervix could not be obstructed by vaginal tampons even if they should extend to the external os. Furthermore, as intimated in the query, not many couples have intercourse during menstruation, and most of them who do know that there is practically no need to use contraceptives at this time. An excellent review of the subject of vaginal tampons was published by Robert L. Dickinson in *THE JOURNAL* June 16, 1945, page 490.

SALICYLATE THERAPY IN ACUTE RHEUMATIC FEVER

RENÉ WÉGRIA, M.D.

AND

KATHARINE SMULL, M.D.

NEW YORK

The use of salicylate in the treatment of acute rheumatic fever has been common practice for many years. The dose of the drug to be employed has been the subject of much speculation, but until recently no quantitative studies had been made. It is only in the last year that there has been an attempt at correlating the efficacy of salicylate therapy with the concentration of the drug in the circulating blood plasma. The importance of maintaining the plasma salicylate level above 350 micrograms per cubic centimeter in the treatment of acute rheumatic fever has been emphasized by Coburn.¹ We have treated a series of patients with acute rheumatic fever with this aim in view and the results obtained are reported in this paper.

METHOD

Selection of Cases.—For this study cases were selected in which a definite diagnosis of acute rheumatic fever could be established. To reach the diagnosis and to follow the course of the disease, the following clinical and laboratory data were used: history, physical examination, blood count, erythrocyte sedimentation rate,² antistreptolysin titer³ and electrocardiogram.

Method of Therapy.—In most cases therapy was not instituted until twenty-four hours after admission in order to permit the collection of preliminary laboratory data. An attempt was made to maintain the serum salicylate level between 350 and 450 micrograms per cubic centimeter. Such a level will be referred to throughout the paper as the "optimal" level. In most cases sodium salicylate was administered orally; enteric coated tablets of 0.3 Gm. were used. In the beginning of the study, doses ranged from 0.9 to 1.5 Gm. every four hours, day and night. Later, in order to reach optimal levels more quickly, double these doses (1.8 Gm.-3.0 Gm. every four hours day and night) were used for the first twelve hours and then the doses were adjusted according to the levels obtained. A few of the patients received intravenous therapy for the

first two or three days. From 7 to 10 Gm. of sodium salicylate dissolved in from 250 to 500 cc. of isotonic solution of sodium chloride was given each day over a period of one to two hours. Contrary to the customary mode of therapy, sodium bicarbonate was not given because it has been shown that it tends to lower the concentration of salicylate in the blood.⁴ Salicylate serum levels were determined by the colorimetric method of Brodie, Udenfriend and Coburn⁵ every day until the level was stabilized, then every other day. The salicylate levels were determined on serum instead of plasma.⁶ Optimal levels were maintained throughout the course of the disease and for two weeks after the erythrocyte sedimentation rate had fallen below 20 mm. in one hour. Such a regimen will be referred to as "adequate" salicylate therapy. Generally the patient was allowed up during the last week of salicylate therapy, was kept one more week in the hospital without salicylate and then was discharged, unless recrudescence of rheumatic activity had occurred.

CASE REPORTS AND RESULTS

Thirty-five patients (37 attacks) were studied. Of these, for various reasons, only 21 patients (23 attacks) were adequately treated according to the criteria defined. Of these 21 patients (23 attacks), 17 patients (18 attacks) responded in a similar manner, the only difference being that, in 9 patients (9 attacks), the rheumatic activity by all available criteria had subsided within two to three weeks after the institution of therapy; in 7 patients (7 attacks) the rheumatic activity had subsided in three and one-half to five weeks and in 2 patients (2 attacks) it subsided respectively in eight and twelve weeks. The first attack of the disease in a patient whose second attack has been included in the group of 17 patients (18 attacks) hereabove, and 4 other patients (4 attacks) are included in the adequately treated group of 21 patients (23 attacks) although they do not completely fulfil our criteria of adequate therapy. These cases will be therefore summarized (see cases 17, 18, 19, 20 and 21).

Figure 1 illustrates a typical case in which rheumatic activity subsided within three weeks.

CASE 1.—A white woman aged 32, American born, had had a sore throat two weeks before admission and was admitted to the hospital complaining of migratory joint pains for two days. There was a history of a tender, red, swollen left ankle at the age of 15. Physical examination revealed a temperature of 101.2 F. and a warm, tender, slightly swollen left knee joint.

6. As previously reported,⁴ salicylate levels in plasma and serum from the same blood sample are not significantly different.

The heart was normal on physical examination. A diagnosis was made of acute rheumatic fever, rheumatic arthritis of the left knee and rheumatic myocarditis. The PR interval was 0.18 second on admission, increased to 0.22 on the tenth day and seven weeks later had decreased to 0.18 second. Oral salicylate therapy (18 Gm every four hours day and night for three and one-half days, then 1 Gm every four hours for three days and then 12 Gm every four hours until discharge) was started on the second hospital day. On the third day the serum salicylate level was 321 micrograms per cubic centimeter and from then on the levels were optimal until discharge. The erythrocyte sedimentation rate declined gradually from 123 on admission to 15 on the twenty-first hospital day. Salicylate therapy was continued until the thirty-ninth hospital day, at which time the patient was discharged free from symptoms.

This was a case of acute rheumatic fever with monoarthritis and electrocardiographic signs of cardiac involvement, in which the erythrocyte sedimentation rate fell and remained below 20 after twenty days of adequate salicylate therapy. The PR interval decreased

Fig 1.—Course of a patient with acute rheumatic fever who was inadequately treated. From top to bottom: temperature (in degrees Fahrenheit), erythrocyte sedimentation rate (in millimeters per hour), serum salicylate level (micrograms per cubic centimeter), oral doses of sodium salicylate (in grams). Time in days.

toward normal while the patient was on salicylate therapy and reached a normal value two weeks after treatment was discontinued.

CASE 17—A youth aged 17, a Puerto Rican, had had polyarthritis at the age of 12 and had "grip" four months before admission. After this illness he was followed for the next three months in the outpatient department. During this time the question of low grade rheumatic activity was raised because of sedimentation rates of 33 and 27 on two occasions, although the patient had no other suggestive signs or symptoms. One week before admission the erythrocyte sedimentation rate rose to 72 and the patient was admitted to the hospital with a diagnosis of acute rheumatic fever, myocarditis, mitral stenosis and insufficiency and aortic insufficiency. Oral salicylate therapy, 12 Gm every four hours day and night, was started on the second hospital day and continued for the first four days, the doses then being adjusted according to the serum levels. Optimal levels were reached on the third day of therapy (fourth hospital day) and were maintained optimal for thirty-eight days except for six days when the levels were slightly below optimal values. On admission the electrocardiogram showed a PR interval of 0.20 second and the erythrocyte

sedimentation rate was 37. On the twentieth hospital day the patient developed cardiac failure, was digitalized and was kept digitalized throughout the rest of the hospital stay. The erythrocyte sedimentation rate fell to 20 on the thirty-eighth hospital day and was 17 on the fortieth hospital day. Salicylates were withdrawn on the forty-first hospital day. The following day the temperature was 100.5 F and rose gradually to 101.5 F, four days later. The erythrocyte sedimentation rate on that day was 51. The patient complained of pains in the knees but had had no recent sore throat or upper respiratory infection. Salicylate therapy was started again (12 Gm every four hours) after an interruption of five days, and optimal levels were reached and maintained from the second day of therapy on. The erythrocyte sedimentation rate fell to 15 on the fifty-sixth day of the second course of therapy (102d hospital day). On the 106th hospital day the cardiac rhythm changed from regular sinus rhythm to auricular fibrillation. From the fifty-sixth day of the second course of therapy the erythrocyte sedimentation rate remained below 20 except for readings of 34, 22 and 30 on the 116th, 120th and 124th hospital days, and salicylates were stopped on the 142d hospital day. After one week without salicylates the erythrocyte sedimentation rate was 7 and the patient was discharged free from symptoms. From the ninety-seventh hospital day on the patient was given 15 to 2 Gm of sulfadiazine per day because the throat culture of the patient in the next bed yielded hemolytic streptococcus.

This was a case of acute rheumatic fever with myocarditis in a patient with one previous attack of rheumatic fever in which optimal levels were maintained for thirty-one out of thirty-seven days of salicylate therapy and in which the erythrocyte sedimentation rate fell from 37 to 20 after thirty-seven days of therapy. A flare-up of the rheumatic process occurred after the salicylates were stopped, and during the second course of therapy optimal levels were maintained for fifty-six days, at which time the erythrocyte sedimentation rate had fallen from 65 to 15. We do not know whether the second attack of rheumatic fever was due to a new hemolytic streptococcus infection or to the recrudescence of the still active rheumatic process which flared up because salicylate therapy was stopped too soon. Because of the latter possibility, in subsequent cases optimal salicylate levels were maintained for two weeks after the erythrocyte sedimentation rate had fallen below 20. The first attack has been included in the adequately treated group although the erythrocyte sedimentation rate had been below 20 for only four days before salicylate therapy was stopped. This seems legitimate, since what we are concerned with in this paper is the duration and not the recrudescence of the disease.

CASE 18—A Negro woman aged 50, whose past history was irrelevant, three weeks before admission had had a sore throat, which was followed by migratory polyarthritis. She was admitted to the hospital with the diagnosis of acute rheumatic fever, polyarthritis and myocarditis. Because of the presence on admission of a rough apical systolic murmur, evidently of organic origin, it was thought that, although the past history was negative, the patient had had a previous attack of rheumatic fever. Oral salicylate therapy (12 Gm every four hours day and night) was started on the second hospital day. Optimal levels were reached on the fourth day and maintained for fifty-one days. On admission the PR interval was 0.26 second and it fell to and remained at 0.16 second from the twenty-seventh hospital day on. The erythrocyte sedimentation rate fell from 117 on admission to 37 on the fifty-fourth hospital day, salicylate therapy was discontinued because it was thought that the elevated erythrocyte sedimentation rate might be due to some condition other than acute rheumatic fever. Within four days the temperature rose to 102.8 F. The patient developed a painful, red swollen left

shoulder and the erythrocyte sedimentation rate rose to 56. Salicylate therapy was resumed after an interruption of four and one-half days; optimal levels were reached within two days and maintained for thirty-eight days. On the twenty-eighth day of the second course of salicylate therapy the erythrocyte sedimentation rate had fallen to 20 and, for the next twelve days, ranged between 18 and 24. The patient then signed out.

This was a case of acute rheumatic fever with polyarthritides and myocarditis in which optimal levels were maintained for fifty-one days, during which time the erythrocyte sedimentation rate fell from 117 to 37. After an interruption of four and one-half days a second course of therapy was started during which optimal levels were maintained for thirty-eight days. By the twenty-fourth day of therapy the erythrocyte sedimentation rate had fallen to 20 and during the next twelve days ranged between 18 and 24.

CASE 19.—A youth aged 17, Irish, had had rheumatic fever at the age of 6. For the past four months he had been having fever ranging between 101 and 103 F. following an attack of "grip." He was admitted to the hospital with the diagnosis of acute rheumatic fever with rheumatic pancarditis. He had mitral stenosis and insufficiency and aortic insufficiency. Oral salicylate therapy (1.5 Gm. every four hours day and night for the first six days, then 1.2 Gm. every four hours) was started on the third hospital day. Optimal levels were maintained from the sixth to the forty-second hospital day. The temperature promptly fell from 102.6 F. on admission to 99.5 F. The erythrocyte sedimentation rate varied between 65 and 118 mm. in one hour. The patient was digitalized on the forty-second hospital day and kept digitalized throughout the admission. To substantiate the diagnosis, salicylate dosage was reduced on the forty-third day for six days and then stopped for three days. On the second day after salicylate therapy had been discontinued, the temperature gradually rose to 103 F. The erythrocyte sedimentation rate remained around 120. Oral salicylate therapy (from 1.2 Gm. to 0.9 Gm. every four hours according to the levels obtained) was started again. When levels were optimal the temperature fell around 99.5 F. On the eighty-fourth hospital day, however, the erythrocyte sedimentation rate was still around 120 and it was decided to reduce the salicylate dosage, so that the patient might be more comfortable. The levels ranged between 200 and 300 micrograms per cubic centimeter for the next two weeks. On the ninety-first hospital day the patient's temperature was 101 F. and he complained of a sore throat. Throat culture yielded hemolytic streptococcus. Salicylate doses were increased so that optimal levels were again maintained; the patient was also given 1 Gm. of sulfadiazine a day, and subsequent throat cultures were negative for hemolytic streptococcus. The patient was discharged after 136 days in the hospital with an erythrocyte sedimentation rate consistently above 100 and a temperature ranging around 99.5 F.

This was a case of acute rheumatic fever in a boy who had had one previous attack of rheumatic fever eleven years previously. He was admitted with the diagnosis of rheumatic pancarditis. Optimal salicylate levels were maintained for thirty-six days. After an interruption of about one week, optimal levels were maintained for thirty days and, after another interruption of about one week, optimal levels were maintained for thirty days more and, after another interruption of ten days, were maintained for thirty-six days. Throughout the hospital stay the erythrocyte sedimentation rate never fell below 60. It is of interest that a loud pericardial friction rub, present on admission, persisted for the first two months of the period of hospitalization.

CASE 20.—Optimal salicylate levels were maintained for twenty-three days, at which time the erythrocyte sedimentation rate had fallen from 120 to 80 and the patient left the hospital.

CASE 21.—The circumstances were similar to those noted in case 20. Optimal levels were maintained for eighty-four days, at which time the erythrocyte sedimentation rate had fallen from 127 to 40 and the patient left the hospital.

These last four cases are included in our adequately treated group because, even after long periods with optimal levels, the erythrocyte sedimentation rate was still far above normal.

Cases 22, 23, 24, 25 and 26 are not used in the estimation of the value of adequate salicylate therapy but are reported here because they show many features of interest. Cases 22, 23 and 24 ended in death from fulminating pancarditis within one week of admission. The history of case 22 is given as illustrative of this group.

CASE 22.—A Negro aged 20, who had been in the hospital for active rheumatic fever with rheumatic myocarditis at the age of 14, had acute rheumatic polyarthritides for three weeks. He was admitted with the diagnosis of acute rheumatic fever with myocarditis and pericarditis, mitral stenosis and insufficiency and aortic insufficiency. Oral salicylate therapy (1.6 Gm. every four hours day and night) was started on the second hospital day and, from the third day on, daily successive serum salicylate levels were 284, 212, 308, 377, 477 and 545 micrograms per cubic centimeter. Rapid digitalization was instituted on the third hospital day. The temperature never fell below 101 F. The heart rate remained above 100 per minute. On the eighth hospital day the temperature and heart rate increased suddenly and the patient died in heart failure with pulmonary edema.

Apparently optimal salicylate levels for three days did not modify the course of a severe rheumatic pancarditis.

CASE 25.—A white man aged 41, who had had migratory polyarthritides and iritis six years previously, had had for the past two months iritis and migratory joint pains. He was admitted with a diagnosis of active rheumatic fever, mitral valvulitis and rheumatic myocarditis. Repeated electrocardiograms showed varying degrees of auriculoventricular block, including temporary complete auriculoventricular block. Oral salicylate therapy (1.2 Gm. every four hours day and night) was started on the second hospital day and, from the third hospital day on, successive daily salicylate levels were above 310 micrograms per cubic centimeter. The temperature and heart rate were normal up to the nineteenth hospital day. Varying degrees of auriculoventricular block (partial, complete and incomplete) persisted throughout the patient's illness. On the nineteenth day, complete auriculoventricular block developed and persisted. On the twenty-second hospital day the patient began to have convulsions. The temperature gradually rose to 106.6 F. The patient lapsed into coma and died.

Because of the varying degree of auriculoventricular block, it was thought that the patient had rheumatic myocarditis in spite of a rather low erythrocyte sedimentation rate (28 mm. in one hour on admission). This impression was later substantiated by the fact that the erythrocyte sedimentation rate rose to 57. Barely optimal levels did not prevent the recurrence of complete auriculoventricular block, which, with myocardial failure, led to death.

CASE 26.—A boy aged 16 years had had rheumatic fever seven years previously. Three months before admission he had had a sore throat and mild joint pains. Two months before admission he was diagnosed in another hospital as having rheumatic fever. He was admitted with a diagnosis of acute rheumatic fever, polyarthritides, rheumatic myocarditis, mitral stenosis and insufficiency and aortic insufficiency. Because it was thought that the patient had subacute bacterial endocarditis, salicylate was not given for the first eight days. Salicylate therapy (1.6 Gm. every four hours day and night)

was started on the eighth hospital day, and in addition approximately equal doses of sodium bicarbonate were given for the first five days. Therefore the levels for the first nine days of salicylate therapy varied between 228 and 392 micrograms per cubic centimeter but were mostly below 300 micrograms. For the next thirty-three days of therapy doses were adjusted according to the levels obtained (0.9 Gm. to 1.6 Gm. every four hours day and night) and the levels were optimal. The erythrocyte sedimentation rate on admission was 30 mm. in one hour and had risen to 66 on the day salicylate therapy was started. After twenty-one days of therapy the erythrocyte sedimentation rate had fallen to 13 mm. in one hour and remained below 13 for the next thirty-one days. Optimal levels were maintained for twenty-one days after the erythrocyte sedimentation rate had fallen to 13, then levels ranging from 218 to 358 micrograms per cubic centimeter were maintained for six more days. Salicylate therapy was then discontinued. Five days before salicylate therapy was stopped, a nose culture yielded hemolytic streptococcus; three days later a circinate erythema developed on the right forearm. During the next two days the temperature rose to 103 F. and a throat culture taken at this time yielded hemolytic streptococcus. The erythrocyte sedimentation rate had risen from 3 to 16. Salicylate therapy was started (0.9 to 1.2 Gm.

Fig. 2.—Fluctuations of the serum salicylate level in a patient receiving one daily intravenous administration of 10 Gm. of sodium salicylate dissolved in 250 cc. of isotonic solution of sodium chloride over a period of two hours. From top to bottom, serum salicylate level (in micrograms per cubic centimeter), dose of sodium salicylate (in grams). Time in days.

every four hours day and night) and from the third day of therapy on the salicylate levels were optimal. The temperature fell to around 100 F., but the erythrocyte sedimentation rate rose progressively to 80 during the next week. The patient died of cardiac failure nine days after the second course of salicylate therapy had been started (seventy-fourth hospital day). The electrocardiogram consistently showed a prolonged PR interval (0.22 to 0.32 second). Because the patient was incompletely digitalized on admission and because full digitalization was completed and maintained throughout the hospital course, the PR interval could not be used as a reliable index of myocarditis. However, it is of interest that the PR interval, which had ranged from 0.22 to 0.25 second, rose to 0.32 second during the rheumatic exacerbation which caused the patient's death.

This was a case of acute rheumatic fever with polyarthritides and myocarditis in a 16 year old boy who already had mitral stenosis and insufficiency and aortic insufficiency. The patient received salicylate therapy for twenty days, during which the erythrocyte sedimentation rate fell from 66 to 13. Levels were maintained optimal for twelve days of this period and

suboptimal for eight days. A second attack of acute rheumatic fever occurred fifteen days after a hemolytic streptococcus had been cultured from the patient's nose. In spite of optimal salicylate levels for six days the patient died of acute rheumatic myocarditis on the ninth day of therapy.

For various reasons the last 9 cases (cases 27-35) were inadequately treated according to the criteria established at the beginning of the study: either optimal levels were never reached or, when reached, were maintained for very short periods of time. These cases are included in our control group.

COMMENT

1. Method of Therapy.—At the beginning of this study a few patients received sodium salicylate by intravenous injection. It became apparent that, even when an optimal serum salicylate level was reached at the end of the infusion, it fell below optimal values by the time of the next infusion. Figure 2 illustrates a case in which maximal fluctuations of serum salicylate levels were observed.

Such fluctuations were thought to be undesirable. In 2 cases, to reach quickly optimal levels and maintain them, the oral and intravenous routes of administration were used simultaneously for the first twenty-four to forty-eight hours and then the oral route was used exclusively. However, by giving orally doses of sodium salicylate which were twice the amount assumed to be the maintenance dose, every four hours day and night for four doses, and then giving the maintenance doses every four hours, day and night, optimal levels are reached within twenty-four to thirty-six hours and are maintained. Therefore the intravenous route of administration offers no obvious advantage over the oral route and the oral route alone was used in most cases. Such massive oral dosage was possible because enteric coated sodium salicylate was used. With few exceptions, no vomiting occurred on this regimen. Although, in cases of cardiac failure, it would undoubtedly be advisable to use acetylsalicylic acid instead of sodium salicylate to avoid the administration of undesired sodium, this was not done because enteric coated acetylsalicylic acid tablets were not available.

2. Toxic Reactions.—The most common and earliest symptom of toxicity was tinnitus. This usually occurred when the salicylate level was around 200 micrograms per cubic centimeter. It is important to note that, before a method for determining the blood salicylate level was established, tinnitus was one of the criteria used by clinicians to adjust salicylate dosage. As higher levels were reached, tinnitus was replaced by deafness, which, in our experience, always disappeared within twenty-four to forty-eight hours after salicylate therapy was discontinued. Some patients were nauseated; very few vomited. A few patients had very slight transient albuminuria.

When blood levels above 500 micrograms per cubic centimeter were established, serious reactions occurred in some patients. Hyperpnea was the most common of these. During the periods of hyperpnea, the serum carbon dioxide content fell as low as 25.8 volumes per cent. A few patients developed sinus tachycardia although the temperature remained normal. The tachycardia subsided rapidly when the level fell to an optimal range. At such high levels apathy and drowsiness were the rule and several patients had intermittent auditory and visual hallucinations. One patient, who was characterized by a psychiatrist as having schizophrenic ten-

dencies when not receiving any medication, developed an acute psychosis. Another patient became stuporous and remained unconscious with levels above 600 micrograms per cubic centimeter. All of these toxic reactions cleared completely when the salicylate level fell below 500 micrograms per cubic centimeter.

3. Evaluation of Results.—Before attempting to appraise the value of salicylate therapy, it is essential to consider the criteria employed to establish the presence and subsidence of rheumatic activity. Unfortunately, there is no simple or specific test which has been shown to measure accurately the degree of rheumatic activity. Local and systemic manifestations of rheumatic activity are not a reliable criterion. Thus, fever, pain, swelling and redness of the joints disappear within twenty-four to forty-eight hours after the beginning of the administration of even small doses of salicylate, although rheumatic activity persists and, indeed, if salicylate therapy is then stopped, all symptoms of acute rheumatic fever reappear. Clinical signs of cardiac involvement such as pericardial friction rub and gallop rhythm are seen in only a few cases, are impossible to quantitate and are known to disappear while rheumatic activity is still present.

The leukocyte count is not elevated in every case and, when it is elevated, may return to normal within four to five days. The antistreptolysin titer is not elevated in every case and does not parallel the degree or duration of rheumatic activity. Electrocardiographic changes are not present in all cases and occasionally are permanent.

The erythrocyte sedimentation rate is the best available criterion with which to follow the course of an attack of acute rheumatic fever and detect rheumatic activity. It is probable that there are patients with rheumatic activity who have a normal erythrocyte sedimentation rate. All the cases that were studied had an elevated erythrocyte sedimentation rate initially. Likewise, it seems possible that the rheumatic activity may subside before the return of the erythrocyte sedimentation rate to a normal value. Therefore the use of the erythrocyte sedimentation rate as the criterion of rheumatic activity might have led us to test our method of therapy in patients in whom rheumatic activity had in reality already subsided. This objection does not, however, seem valid in our cases, because all of the patients studied had, in addition to a high erythrocyte sedimentation rate, one or several other manifestations of rheumatic activity. A very pertinent objection to the use of the erythrocyte sedimentation rate as a criterion is the fact that it is a nonspecific test and can be modified by many causes. Whereas this is undoubtedly true, complicating conditions apparently did not modify the erythrocyte sedimentation rate in this study, in which careful search was made for them. For these various reasons it seemed reasonable to consider the erythrocyte sedimentation rate as a reliable criterion of rheumatic activity with the qualifications mentioned and to use it to follow the course of the disease.

The question whether adequate salicylate therapy shortens the course of an attack of acute rheumatic fever can be determined only by comparing a group of patients adequately treated with a control group. The adequately treated group consists of 21 patients (23 attacks). Our control group consists of 19 patients (19 attacks). Nine of these were patients under our own observation and were not adequately treated for various reasons. In 2 of these 9 patients optimal

levels were never reached; in the other 7 patients optimal levels were obtained only for short periods. The remaining 10 patients of the control group had acute rheumatic fever and were admitted to the Presbyterian Hospital in 1943; none of these patients received consistently more than 3.6 Gm. per day of sodium salicylate and most of them received equal doses of sodium bicarbonate. Although salicylate levels were not determined, it can safely be assumed from what we observed in patients receiving similar doses and on whom we determined salicylate levels, that optimal levels were never reached.

In analyzing the results obtained, one must bear in mind that there are several known factors other than drug treatment which might modify the course of acute rheumatic fever and which might have masked the possible efficacy of adequate salicylate therapy. These factors are (1) the age of the patient, (2) the number of previous attacks of rheumatic fever, (3) the existence of previous rheumatic cardiac involvement, (4) the existence of cardiac involvement during the attack studied, (5) the duration of the attack before therapy is instituted and (6) the possibility of yearly variations in the intensity of the disease.

Comparing the adequately treated and the control groups and taking the age of 13 as the end of childhood, there are in the adequately treated group 20 adults and 1 child, and in the control group 15 adults and 4 children. In the adequately treated group, 13 patients had had a previous attack of rheumatic fever and 10 patients in the control group had had a previous attack. In the adequately treated group 8 patients and in the control group 7 patients had had previous rheumatic cardiac involvement. Thirteen patients in the adequately treated group and 10 patients in the control group had cardiac involvement during the attacks of rheumatic fever that were studied. The duration of the attacks before therapy was instituted is essentially the same in the control group and in the adequately treated group. All patients in both groups were treated within two months of the onset of the disease, with the exception of 1 patient of the control group who had had symptoms for three months and 2 patients in the adequately treated group who had had symptoms of rheumatic fever, 1 for three months and 1 for four and one-half months. Whereas fluctuations in the severity of the disease are believed to exist from year to year, these would hardly appear to be of sufficient significance to vitiate the results.

Figure 3 shows the variation of the erythrocyte sedimentation rate in the group of adequately treated patients over a period of sixty days and figure 4 shows the variation in the erythrocyte sedimentation rate in the control group over the same period of time. The accompanying table summarizes the results obtained in the two groups.

At the end of two weeks the erythrocyte sedimentation rate was still above 20 in all cases of the control group and in 22 out of the 23 attacks of the adequately treated group. At the end of three weeks the erythrocyte sedimentation rate was still above 20 in 16 cases of the adequately treated group and in 16 cases of the control group. At the end of four weeks the erythrocyte sedimentation rate was above 20 in 13 cases of the adequately treated group and in 12 cases of the control group. At the end of five weeks the erythrocyte sedimentation rate was still above 20 in 10 cases of the adequately treated group and in 8 cases of the control

group At the end of six weeks the erythrocyte sedimentation rate was still above 20 in 6 cases of the adequately treated group and in 4 cases of the control group Evidently, when the results obtained in a group of patients who receive adequate salicylate therapy are compared with the results obtained in a group of patients

onset of their symptoms It is worthy of note, however, that 4 out of these 5 responded promptly and the erythrocyte sedimentation rate fell below 20 within two to three weeks

SUMMARY AND CONCLUSIONS

1 In a series of patients with acute rheumatic fever, optimal serum salicylate levels (350 to 500 micrograms per cubic centimeter) were established promptly Such levels were maintained in most cases until the erythrocyte sedimentation rate fell and remained below 20 for two weeks Such therapy is referred to as adequate salicylate therapy.

2 To achieve optimal levels promptly, oral intravenous and combined routes of administration were used As a result of the study of the first cases treated, oral administration was used exclusively in most cases Doses of sodium salicylate twice the maintenance dose were given every four hours for the first twelve hours, then the maintenance dose was given and adjusted according to the levels obtained The maintenance dose ranged between 0.9 and 1.8 Gm every four hours day and night and was roughly computed from the weight of the patient The use of enteric coated sodium salicylate tablets prevented in most cases the vomiting which so frequently follows the administration of large doses of salicylate

Fig. 3—Variations of the erythrocyte sedimentation rate over a period of sixty days in the group of a adequately treated patients Time in days

in whom optimal serum salicylate levels were never reached or, when reached, were maintained for very short periods, it is obvious that adequate therapy does not shorten the duration of an attack of acute rheumatic fever However, it is possible that adequate salicylate

Fig. 4—Variations of the erythrocyte sedimentation rate over a period of sixty days in the control group of patients Time in days

therapy instituted within a few days of the onset of rheumatic fever might have proved efficacious in shortening the course of the disease This cannot be determined from our study because only 5 patients (5 attacks) out of the 21 patients (23 attacks) in the adequately treated group were treated within one week of the

Number of Patients Whose Erythrocyte Sedimentation Rate Has Still Above 20 Mm per Hour in (1) the Control Group and (2) the Adequately Treated Group After Two, Three, Four, Five and Six Weeks of Hospital Stay

	2 Wks	3 Wks	4 Wks	5 Wks	6 Wks
Control group (19 patients, 19 attacks)	13	10	11	8	4
Adequately treated group (21 patients, 23 attacks)	16	1	10	0	0

3 The course of an attack of acute rheumatic fever was compared in two comparable groups of patients The control group (19 patients, 19 attacks) consisted of 10 patients who received such small doses of acetylsalicylic acid that from our experience it can be safely assumed that their blood salicylate level although not determined, never reached optimal values, and 9 patients in whom optimal levels were never reached or reached only for short periods The second group (21 patients, 23 attacks) received adequate salicylate therapy

4 The course of an attack of acute rheumatic fever is not shortened by adequate salicylate therapy It is possible, however, that the course of the attack might be shortened by early institution of adequate salicylate therapy, i. e. within one week of the onset of symptoms of acute rheumatic fever

Yellow Fever—Amongst human infectious diseases only plague can rival yellow fever in its influence on human history and in the sinister impression it has made on the human mind For three centuries it was persistently associated with the slave trade between West Africa and the Caribbean region and it played probably a greater role than any other factor in determining the course of war and piracy in the West Indies during the eighteenth and nineteenth centuries Yellow fever was notoriously a disease of tropical ports and of the ships particularly slave ships, that visited them The two famous literary legends of the Flying Dutchman and the Ancient Mariner both reflect stories of ships stricken with the disease—Burnet, Frank MacFarlane Virus as Organism Cambridge Mass Harvard University Press 1945

EVALUATION OF PENICILLIN IN
GONORRHEA TREATMENT
AND CONTROL

RICHARD A. KOCH, M.D.

WILLIAM Y. HOLLINGSWORTH, M.D.

Medical Director, United States Public Health Service; Medical Officer
in Charge, United States Marine Hospital, San Francisco
SAN FRANCISCO

Our purpose in this article is to evaluate the role of penicillin in the treatment and control of gonorrhea. Our results do not justify the prevailing optimism held by the public and many of the medical profession as to the efficacy of penicillin as an easy, infallible cure of gonorrhea. Some investigators have reported from 95 to 100 per cent cures with varying doses of penicillin.¹ The full benefits of penicillin therapy are not achieved unless a careful search is made for patients who still harbor the disease. Penicillin will cure most cases of gonorrhea, but cure is not necessarily accomplished by the first course of the drug or by penicillin alone. Supportive treatment such as pyrotherapy and the sulfonamides is necessary at times even with repeated courses of penicillin. It is in the interest of public health that the limitations of the drug should be well understood.

Some workers have implied that penicillin-treated gonorrhea patients need only a brief observation period or have intimated that an observation period is unnecessary.² One investigator intimated that all failures can be determined by the presence of a urethral discharge.³ It has been reported also that gonococcal cultures are unnecessary in the follow-up of penicillin-treated gonorrhea patients and that cure may be based on cessation of clinical symptoms.⁴ Others have indicated a need for a greater period of observation.⁵ Our statistics indicate that an important percentage of patients do fail on the initial and even subsequent courses of penicillin and that these failures are frequent enough

to warrant diligent search for gonococci following such medication; otherwise we shall produce carriers unaware of their infectiousness. The profession and the public should be aware that the absence of clinical symptoms is not satisfactory proof of cure.

This report deals with a comparison between a brief (eight days) observation period under hospital conditions and a longer (nine weeks) observation under clinic conditions. It includes a review of the records of patients treated with an initial course of 200,000 units of penicillin at the San Francisco United States Marine Hospital and at the San Francisco City Clinic from Aug. 23, 1944 to April 20, 1945. This amount of penicillin was used because a review of previous records at the City Clinic⁶ showed that a smaller amount of penicillin was not as therapeutically efficacious as 200,000 units, and a greater amount of penicillin used at the Marine Hospital indicated no more promising results than the use of 200,000 units. It is our purpose to evaluate the records of those patients treated with 200,000 units of penicillin to determine the failure rate of this type of medication to establish the minimum observation period which is commensurate with adequate public health safeguards and generally practicable to the average treatment agency, and to contemplate the place that penicillin is likely to play in the public health control of gonorrhea.

EXAMINATION AND TREATMENT

The male patients were diagnosed by the finding of gonococci by spread or culture, or both, in the urethral discharge. If the urethral discharge was not present, or if gonococci were not found in the discharge, the demonstration of gonococci in the culture of the prostatic fluid was the determining factor. Female patients were diagnosed by a finding of gonococci by the spread or culture method in material secured from the urethra and cervix. The laboratory work was performed in the laboratories of the United States Marine Hospital or the San Francisco City Clinic.

The prostatic fluid material to be examined for culture at the Marine Hospital was secured by prostatic massage and the expressed secretion was collected directly on the Petri dish containing the culture medium. This preparation was placed in the incubator within a maximum period of fifteen minutes. This procedure was followed both for diagnostic cultures and for tests of cure. The material to be examined for culture at the City Clinic was secured on a sterile cotton-tipped applicator and was placed in 0.5 to 1.0 cc. of nutrient broth and refrigerated at 4 to 8 C. with a delay of not more than two or three minutes. The preparation was streaked on culture plates within a period of one to three hours and placed in the incubator. All culture plates were incubated forty-eight hours at 35 to 36 C. in a moist atmosphere of approximately 8 per cent carbon dioxide tension. Following this the plate was flooded with p-amino-dimethylaniline monohydrochloride. Oxidase-positive colonies were examined morphologically and tinctorially for gonococci.

The City Clinic laboratory performed 325 sugar fermentation tests, all of which confirmed the positive culture findings. The hospital laboratory obtained the same results on 25 positive cultures. Because of the complete confirmation of this number of routine positive gonococcal cultures, which included positive cultures for diagnosis and for tests of cure, we do not

feel it necessary to confirm all positive cultures by the sugar fermentation test. The nutrient broth used was Difco proteose-peptone No. 3, slightly enriched with glucose and diluted with an equal amount of ascitic fluid. The plate medium was composed of one third Difco proteose-peptone agar No. 3, one third Difco hemoglobin solution and one third sterile ascitic fluid. Tyrothricin in a dilution of 1:25,000 was employed as an inhibiting factor for saprophytic organisms in this medium.

It is of interest to point out that the hospital laboratory found less saprophytic organisms present on plates when the prostatic fluid was massaged directly onto the culture medium than when the material was first secured on a sterile cotton-tipped applicator.

Penicillin in isotonic solution of sodium chloride was administered intramuscularly, 80,000 units being administered on the first injection and 40,000 units being administered on each of the three subsequent injections at three hour intervals. The solution of penicillin was prepared on the day of treatment and refrigerated throughout. During the initial course of penicillin therapy no other treatment was given. Most of the patients treated at the Marine Hospital had no previous

† According to our criterion of cure.

sulfonamide medication, while the majority of the patients who were treated at the City Clinic had received one or more courses of sulfathiazole or sulfadiazine. All patients had a positive spread or culture prior to penicillin medication.

The minimum criterion of cure on all patients at the Marine Hospital was two consecutive negative cultures secured by prostatic massage, the first one being taken at least forty-eight hours and the second being taken at least ninety-six hours after medication was completed. In addition the patient had a provocative urethral sound passed, usually size 24 to 26 F., within twenty-four hours after treatment and before the first culture. Wherever possible a third culture was taken at the end of six days. Except in 2 instances all these patients were confined to the hospital under ambulatory conditions during their entire period of observation.

The minimum criterion of cure on all patients at the City Clinic was three consecutive negative cultures secured by prostatic massage in the male and material expressed from the urethra and cervix in the female taken over a four week period with a minimum of one week between cultures. No provocative sounds were passed on these patients. Weekly cultures for the first four weeks, a fifth culture at the end of eight weeks and a sixth culture at the end of twelve weeks of observation were taken wherever possible. All these patients were observed under clinic conditions.

STATISTICAL ANALYSIS

This report concerns 485 patients who were treated with an initial course of 200,000 units of penicillin. The report does not include 103 patients results of whose treatment are unknown. The results of treatment of these patients are unknown since they transferred or lapsed prior to meeting the minimum criterion of cure established.

At the Marine Hospital a failure was determined if a positive culture or spread was obtained while the patient was hospitalized. Two of the patients who were reported as having failed were found to have positive cultures on their return checkup at the hospital. Since these patients had no clinical symptoms of reinfection and denied sexual intercourse, they were considered to be failures. At the City Clinic a failure was determined if a positive culture was obtained following penicillin therapy and there was no clinical evidence of new infection.

We considered a reinfection to have occurred in those male patients who developed a profuse urethral discharge following an asymptomatic state after penicillin therapy. We did not consider that a reinfection had occurred in those patients who had a slight mucoid moisture immediately following therapy. It was not possible to establish such a satisfactory criterion for female patients, because the presence of a cervical discharge is not clinical proof of a new infection. Comparison shows that the failure rate by sex is not significantly different; consequently an evaluation of the failure rate in the male is probably applicable to that in the female. We are aware that this is contrary to the general opinion, although one of us has reported elsewhere⁶ a series which appears confirmatory of similar rate of failure in the sexes.

Table 1 gives the results of treatment with one course of 200,000 units of penicillin of 269 hospitalized cases at the Marine Hospital and of 216 outpatients at the City Clinic. Thirty-four (13 per cent) of these hospitalized patients failed to respond to treatment and 235 (87 per cent) were cured.

Of the 216 patients treated at the City Clinic 34 (16 per cent) were failures and 182 (84 per cent) were cured. Although these were outpatients with opportunity for sexual exposure, the failures were not considered to be reinfections since there were no clinical symptoms, as defined, indicative of new infection in the male and no history of sexual exposure except for 4 male patients with profuse urethral discharges following an asymptomatic state after penicillin therapy who were possible reinfections. Two males and 4 females were possible exceptions also because they admitted sexual exposure, but reinfection was not substantiated by clinical symptoms in the male cases.

The failure rate for the patients treated at the Marine Hospital is lower than would probably be found if the observation period was extended to include a period greater than one week, as at the City Clinic we found many failures after one week of observation. However, keeping these patients for longer periods of observation is not practical. It is possible that the passage of the provocative sound led to the finding of failures sooner than they might ordinarily have occurred.

An evaluation of the failures occurring at the Marine Hospital and at the City Clinic by observation period and by sequence of culture showing failure is presented in table 2. The observation period in this table is defined as the period from the administration of the penicillin to the taking of the first positive culture. Of

the 34 failures at the Marine Hospital. 13 failures (39 per cent) were found after an observation period of five days or longer with positivity occurring on an average on the second culture. Positive cultures were obtained on the remaining 21 failures (61 per cent) from one to four days following treatment.

At the City Clinic 13 failures (38 per cent) were detected by the first week of observation. Twenty-one failures (62 per cent) were detected after one to four weeks of observation, with positivity occurring on an average on the second culture. Thirteen of the failures (38 per cent) had positive cultures after five or more weeks of negative observation.

Table 3 is a presentation of the average number of negative cultures obtained, by observation period, for 235 cured cases at the Marine Hospital and 182 cured cases at the City Clinic. The period of observation is that period from the day of treatment with penicillin until the day on which the last culture was taken. It is to be noted that 206 cured cases (88 per cent) at the Marine Hospital were observed for a period of six days or longer, with an average of three consecutive negative cultures obtained.

At the City Clinic 117 cured cases (64 per cent) were observed for a period of eight weeks or more, with an average of five consecutive negative cultures obtained.

It is of interest to discuss the treatment results of those patients who failed to respond satisfactorily to an initial course of 200,000 units of penicillin. Of the 34 failures occurring at the Marine Hospital, 30 patients were retreated with a second course of 200,000 units of penicillin. Twenty-four of these cases fulfilled the minimum criterion of cure, as defined; 6 failed. The failures were retreated with a third course of 200,000 units of penicillin; 4 were cured with penicillin alone, 1 was cured with penicillin and sulfadiazine and 1 failed. This failure was treated with a fourth course of 200,000

sulfathiazole; the remaining 4 failures were not given further treatment at the hospital.

Of the total 34 patients who failed at the City Clinic, 27 were given a second course of 200,000 units of penicillin. Of this number 8 failed, 10 were cured and the results of 9 are unknown. Five patients were given a third course of 200,000 units. Of these 2 failed, 1 was cured and the results of the remaining 3 are unknown.

TABLE 3.—Average Number of Negative Cultures Obtained, by Observation Period, for 235 Cured Cases at the San Francisco United States Marine Hospital and for 182 Cured Cases at the San Francisco City Clinic

United States Marine Hospital (S. F.) (Hospitalized Patients)				San Francisco City Clinic (Outpatients)

Total.....		235	100	Total.....		182	100

One patient who was given a third course was treated simultaneously with artificial fever therapy and failed. This patient was retreated with 400,000 units and transferred. The results of treatment that were unknown included those patients who lapsed with incomplete tests of cure, those who were transferred prior to completion of tests of cure or those patients who were still under observation. Of the 27 failures occurring on the initial course of 200,000 units, 11 patients were apparently cured by additional treatment with penicillin alone. Of those patients about whom we have information, none were found to resist all treatment completely.

COMMENT

A review of our statistical findings indicates a failure rate of sufficient import to justify an observation period after treatment. We are not prepared to state the exact length of this observation period. It cannot be longer than the availability of hospital beds and other factors permit, but it should be long enough to meet satisfactory criteria of cure. The fact that only 10 (29 per cent) of the failures occurred on the first culture over an average observation period of one to two days indicates that the taking of one follow-up culture is not conclusive or adequate evidence of cure. It is important in the analysis of the Marine Hospital failures to note that in all except 2 cases reinfection was improbable.

In view of the similarity of failure rate at the two treatment agencies, it would be indicated that the failure rate at the City Clinic was not to a large degree due to reinfections. However, a review of the period of observation of patients at the City Clinic would indicate the desirability of maintaining an observation period beyond that of the Marine Hospital if this is commensurate with the operation of the treatment agencies. It is to be noted that 21 failures, or 62 per cent of all the failures occurring at the City Clinic, were discovered after the first week. It is probable that the earlier detection of failures at the Marine Hospital was due to the passage of sounds.

The trauma to the congested mucosa caused by this procedure possibly brought organisms to the surface

units of penicillin with typhoid pyrotherapy and failed. He was then cured on the fifth course of 200,000 units of penicillin with sulfathiazole and artificial pyrotherapy.

Four of the original 30 retreated failures were given a second course of penicillin with thyroid pyrotherapy or artificial fever therapy simultaneously, which resulted in 2 failures and 2 cures. One patient was given artificial pyrotherapy simultaneously with the third course of penicillin and was cured. Of the 34 failures occurring on the initial course of 200,000 units, 30 patients were apparently cured by subsequent treatment with penicillin either alone or with concurrent pyrotherapy and

which would otherwise have remained dormant. There is reasonable historical evidence indicating that these dormant organisms can produce a carrier state and subsequently lead to an activation of clinical symptoms.⁷ We have further evidence for our belief that it is possible to have prostatic,⁸ cervical and urethral foci of walled off organisms that may later break down and produce a recurrence or carrier state. That gonococci may be dormant over a long period of time is indicated by 3 urologic cases with a history of urethral infection suggestive of gonorrhea twenty to forty years previously with no interval activation of symptoms who have had activation of their symptoms following urethral instrumentation. These patients vary in age from 60 to 75 years. They claim no sexual contact for a period range of ten to fifteen years.

It is important to point out to those who would be critical of the passage of urethral sounds in the presence of penicillin-treated acute gonorrhea that in over 700 patients we have had no complications resulting from this procedure. These sounds were passed within the first twenty-four hours following completion of the penicillin therapy, and none were passed sooner than twelve hours thereafter.

Five penicillin-treated patients at the Marine Hospital, not included in the present series and who have shown resistance to treatment, are worthy of mention. One patient received three separate courses of 100,000 units of penicillin but still showed positive spreads and cultures. He then received 200,000 units of penicillin with persistent positive spreads and a final course of 200,000 units of penicillin along with typhoid pyrotherapy before two consecutive negative cultures could be obtained. Four other similar cases were treated; 1 of these required 1,600,000 units of penicillin simultaneously with sulfonamides and artificial fever therapy in order to effect a cure. In our experience patients with gonococcal epididymitis or prostatitis respond as well to penicillin therapy as those without such complications.

We believe that a plan of observation depending on criteria of cure in which the patient is instructed to return for examination only with recurrence of clinical symptoms following penicillin therapy or a plan of securing only one post-treatment gonococcus culture is inconsistent with adequate public health control.

An interpretation of our statistical results would indicate the importance of obtaining three consecutive negative cultures over a four week observation period. However, as this type of observation is not practicable to all treatment agencies, we recommend an irreducible minimum criterion of three cultures over a one week period. We feel that this short observation period should be used only when the longer is impossible. Where practicable we believe it is still desirable to maintain the patient on a three months observation period during which time the patient has had a minimum of six consecutive negative cultures. A period longer than this is inconsistent with the law of diminishing returns.

Penicillin is unquestionably the most valuable therapeutic agent that has thus far been available to the medical profession in the treatment of gonorrhea. If the

limitations of this therapy are adequately appraised and if the doctor is aware of the necessity of a careful observation period based on the use of adequately secured, prepared and examined cultures, penicillin should contribute to the reduction of the incidence of gonorrhea.

It should be realized that the control of gonorrhea is not in the hands of the medical profession alone. The social factors related to the spread of the disease are beyond the scope of the profession. The control of those social factors that are concerned with the dissemination of venereal disease must be assumed by all of the community agencies responsible, namely the parents, the church, the state, the school and all other agencies which have a role in shaping the social environment of youth.

ADDENDUM

This article was submitted to the Surgeon General of the United States Public Health Service for approval for publication. It was returned approved with some pertinent comments:

1. It was suggested that perhaps our cure rate would be improved if penicillin was administered at two hour intervals. One of us is now administering the same total dosage at two hour intervals (200,000 units); another of us is trying an initial total dosage of 300,000 units at three hour intervals. We have no completed statistics on the results on the two hour interval cases, and we do not wish to draw final conclusions from a small series, but with the use of 300,000 units at the Marine Hospital, we have encountered a failure rate of 13 per cent.

2. It is hoped that other investigators in this field will repeat our work of sugar fermentation tests. We are continuing these tests in both our clinics on cultures used for diagnosis and as tests of cure.

3. The comments also pointed out that an objective view should be taken of hospitalization for the treatment of gonorrhea. When we can assure ourselves that our cure rate is 95 per cent or better, we feel that hospitalization for gonorrhea is not justified.

4. The comments also suggested that trauma produced by sounds might interfere with phagocytosis and produce a relapse. We believe that, because of the fact that failures at the City Clinic, where sounds were not passed, and the Marine Hospital, where sounds were passed, were so statistically comparable, these figures invalidate the suggested hazard of passing sounds.

The comment on this same subject pointed out that passage of sounds by a trained urologist in the hospital would give a much larger margin of safety than a similar procedure in the hands of a general practitioner; with this opinion we are in complete agreement.

SUMMARY

1. Of 485 gonorrhea patients treated with an initial course of 200,000 units of penicillin, 68 (14 per cent) were not cured.

2. Hospitalization of gonorrhea patients does not appear to affect the failure rate. This would indicate that failures occurring in outpatients are probably not reinfections.

3. Minimum criteria of cure, including multiple cultures in penicillin-treated gonorrhea patients, are indispensable to the public health control of the disease.

4. We cannot definitely report a case of complete penicillin resistance; however, 1 in 7 failed on the first course of treatment, many of the retreated ones

required more than one repeat course, and in some of them sulfonamides and pyrotherapy were administered simultaneously.

5. We have been unable to confirm the necessity for the usually accepted practice of differentiating gonococci from other members of the *Neisseria* family by sugar fermentation tests; 350 laboratory observations, although not conclusive evidence, constitute a not inconsiderable group on which to base an opinion.

6. In the control of gonorrhea the medical profession must be aware of the limitations of penicillin therapy, the possibility of producing a carrier state and the social factors related to the spread of the disease.

TULAREMIA

ANALYSIS OF 225 CASES

ROSCOE L. PULLEN, M.D.

AND

BYRON M. STUART, M.D.

NEW ORLEANS

In the period from Jan. 1, 1928 to July 1, 1944, 225 cases of tularemia were observed in the Charity Hospital of Louisiana at New Orleans. As this is a large series of cases to be studied in a single institution, analysis of these cases from the clinical point of view seems worth while. We shall not attempt an exhaustive survey of the literature, as it is believed that the size of this group of cases will provide a representative sampling of the difficulties in diagnosis and treatment of tularemia infections in general.

It is doubtful whether tularemia is a growing disease in incidence as well as in morbidity and mortality. The apparent increase in some sections of the country is probably based on a more general awareness and increasing recognition of the disease. The diagnosis of tularemia is to be considered in any acute febrile illness, and the remarkable similarity of tularemia infections to other febrile diseases, such as influenza, psittacosis, atypical pneumonia, brucellosis, typhoid, tuberculosis, infectious mononucleosis, leukemias, lymphomas, fungous infections of diverse types, and various diseases accompanied by septicemia and bacteremia, adds to the difficulty and frequently renders impossible the diagnosis based on clinical data. Consideration of the clinical features of our group of 225 cases will emphasize the variety of expressions of tularemia infections.

CLINICAL FEATURES

Of the 225 cases of tularemia available for study, 181 were ulceroglandular, 7 were oculoglandular, 14 were of the typhoidal form and 23 were apparently of the glandular variety of the disease. In the selection of these cases the following criteria were considered acceptable for confirmation of the diagnosis of tularemia: (1) significant or rising agglutinin titer, (2) positive blood culture, (3) aspiration biopsy and animal inoculation and (4) autopsy examination with animal inoculation.

Incidence.—As seen in chart 1, the highest incidence of tularemia at Charity Hospital occurred in 1940, with the next greatest frequency in 1935. We have no adequate explanation for the variations in incidence from year to year, especially in view of the fact

that the rural population in Louisiana is fairly stable and the number of annual admissions to Charity Hospital during the same period has steadily increased. The present downward trend is gratifying and may be evidence both of greater knowledge of tularemia among the lay population with resultant increase in prophylaxis and also of a considerable reduction in hunting during recent seasons.

As one would expect, the highest incidence (chart 2) reaches its peak in December, which is at the height of the hunting season. A few cases of tularemia are seen, however, at all times of the year.

Racial Distribution.—Of the 225 patients, 132 were white and 93 were Negroes. This is proportional to the admissions of white and colored patients during the same period and does not, therefore, reveal any significant differences in racial susceptibility to the disease.

Sex.—There were 84 white male patients, 50 colored males, 48 white females and 43 colored females. These data did not show any significant differences in susceptibility based on sex. The slight preponderance of male patients may be readily explained on the basis of contacts with the animal reservoirs of the disease.

Age.—The age factor too is related to the contacts of the patient group. The average age for our group

Chart 1.—Incidence of 225 cases of tularemia according to years.

of patients was 34.9 years. The youngest patient was a white girl of the age of 3 years who was bitten by a captive wild rabbit. The oldest patient in this series was a colored man of 73.

Contacts.—The wide variety of animal contacts capable of infecting man with *Bacterium tularensis* (*Pasteurella tularensis*), the organism which causes tularemia, is not appreciated as highly as it should be. In our group 176 patients gave a history of definite contact with rabbits, 6 to ticks, 3 to squirrels and 1 each to mink, raccoon, opossum, dog, cat and rat. In 34 instances a definite contact was not established.

Whereas it is estimated¹ that about 90 per cent of human infections with tularemia result from contact with the tissues, body fluids or pelts of the cottontail rabbit, jack rabbit and snowshoe hare, other sources of infection reported in the literature include an imposing list of rodents, gallinaceous birds and other animals, such as the dog, cat, coyote, fox, hog and sheep. Infection by ingestion of insufficiently cooked rabbit meat has been reported occasionally. Transmission by the bite of the horse fly and deer fly has occurred in the Western states. Ticks may transmit the disease to man in any section of the country. In the Western states the wood tick *Dermacentor andersoni* and the

1. Feshay, L.: Tularemia, in Bercovitz, Z. T.: Clinical Tropical Medicine, New York, Paul B. Hoeber, Inc., 1944.

dog tick *Dermacentor occidentalis* are the chief vectors; elsewhere the dog tick *Dermacentor variabilis* assumes importance. Ticks are of particular interest in that the primary lesion of tularemia following the bite of the tick may occur on unexposed portions of the body. Outbreaks of tularemia following the ingestion of contaminated water have occurred in Russia. Thus it is evident that historical inquiry concerning exposure to animal contacts must consider a wide variety of possibilities.

Incubation Period.—The incubation period for the entire group usually varied from two to six days (average 4.6 days) with the shortest period being one day and the longest fifteen days.

Primary Lesion.—A primary lesion of tularemia developed in 188 cases. Seven of these were examples of ophthalmic tularemia. The lesions were located on the hands or fingers in 175 instances. Of these, 91 were on the left hand and 82 on the right hand, and in 2 patients a finger on each hand was involved. Four patients presented multiple lesions of one hand or fingers. The largest number of primary lesions to occur in any 1 case was four. A white girl 4 years of age was found to have a primary lesion on her forehead. Lesions of the right shoulder, right axilla, right

ment; hence it is probable that the primary lesion was overlooked in these patients.

The location of the regional lymphadenopathy was not always diagnostic. One female patient without evidences of a primary lesion presented a nodular type of lymphangitis which extended from the axillary nodes along the outer border of the pectoralis muscle to involve the breast. A biopsy was taken because malignancy was suspected. One white male presented lymph node enlargement in the left supraclavicular fossa which was thought at first to be metastatic from a primary malignant growth elsewhere. With the exception of the 7 cases of oculoglandular type of tularemia, cervical lymphadenopathy occurred in only 14 instances. Seventeen patients presenting primary lesions were found to have generalized lymph node enlargement of some degree instead of regional lymphadenopathy. Of these, 7 patients had a palpable spleen. In passing, it may be said, however, that 6 of 14 patients with typhoidal tularemia had palpable spleens as compared to 3 of 23 cases of the glandular type of the disease.

In 47 cases (22.2 per cent) suppuration of the glands occurred and the glands either ruptured spontaneously or were incised after evidences of secondary infection subsided. Data available in 192 instances indicated that the known duration of adenitis varied from seventeen days to two hundred and nineteen days. The average duration of known adenitis for these cases was 46.4 days. No determinations concerning recurrence of lymphadenopathy are permissible in view of inadequate observations of the patients following discharge from the hospital.

Subcutaneous Nodules.—Subcutaneous lymphangitic nodules were observed on the hand, forearm or arm of 18 patients (8.0 per cent). They were found on either the anterior or the posterior surface of the arm or forearm along the route of lymphatic drainage toward the involved axillary nodes. These nodules were usually firm, movable and nontender. In a few cases, however, the nodules became attached to the skin and progressed to suppuration. As is characteristic of tularemia, visible lymphangitis between the primary lesion and the regional buboes was noted in only 1 patient, and this was a nodular lymphangitis.

Skin Manifestations.—In 19 instances in this series (8.4 per cent) a skin eruption occurred. In 9 patients the eruption was described as diffuse and papular. In 6 cases, lesions typical of erythema nodosum were widely distributed over the body. Doubt existed as to the etiology of the remaining 4 patients because sulfonamides were being administered when the skin manifestations first became apparent, and in each of these cases the skin eruption subsided within four days after the sulfonamides were discontinued. In the first 15 cases, however, the cutaneous eruption usually appeared during the second or third week of the disease and lasted from a few days to three weeks or more. It was most prominent on the arms and neck, although erythematous macular lesions of the palms of the hands were also frequently present. The cutaneous eruption was usually bilateral and symmetrically distributed.

Herpes labialis was present in 17 cases and was thought to be of no more significance in tularemia than in association with other febrile diseases.

Oculoglandular Type.—This type of tularemia was observed in 7 cases (3.1 per cent) in our series (table 1). Rabbits were the source of contact in 6 instances, while the only history of contact obtained

Chart 2.—Seasonal incidence of 225 cases of tularemia.

knee, right elbow and left inguinal region were attributable to tick bites.

The initial lesions usually became noticeable within a few hours in instances in which trauma to the site had occurred. In instances in which a history of previous trauma could not be obtained the primary lesion developed less rapidly, a period as long as seven days being required in a few cases.

Adequate data were available to determine a relatively accurate duration of the primary lesion in 148 cases. The shortest healing time was nine days in 1 case, while a patient presenting an inguinal lesion secondary to a tick bite required one hundred and four days for complete healing. The average duration of the primary lesions was 32.09 days.

Glandular Involvement.—Evidences of lymph node enlargement were manifest in 211 cases. Of these, regional lymphadenopathy secondary to a primary lesion occurred in 181 cases and may therefore be classified as ulceroglandular tularemia. Seven patients presented cervical lymphadenopathy secondary to primary ophthalmic lesions. No evidences of primary lesions could be discovered in the remaining 23 patients. However, 14 of these had unilateral axillary involvement with or without epitrochlear glandular enlarge-

from the remaining patient, a white man 20 years of age, was that of mashing a tick between the finger and the forethumb. No digital lesion developed. Within nine days, however, a severe conjunctivitis with subsequent cervical lymphadenitis developed. One fatality occurred among the clinical forms of oculoglandular tularemia, a colored man aged 35, who died on the fourteenth day of his illness. In the remaining 6 patients who eventually recovered no complicating ocular disturbances were observed during the convalescent period.

Pneumonic Involvement.—Of this series, 30 cases presented evidences of pneumonia, an incidence of 13.33 per cent, while 7 cases showed pleural effusions. Of this group, however, only 21 cases, an incidence of 9.33 per cent, fulfilled the criteria for the diagnosis of tularemic pneumonia. These cases of tularemic pneumonia have been reported elsewhere.²

The only history of contact being that of a bite by his dog, which had recently eaten a squirrel. Survey of the spinal fluid revealed a cloudy fluid, 220 cells, 4 plus globulin, 60 mg. of sugar per hundred cubic centimeters and pressure of 240 mm. of water. Spinal fluid culture and smear were negative. The patient eventually recovered.

Venous Thrombosis.—Venous thromboses were observed in 3 instances. The femoral veins were affected twice and the antecubital vein once. The symptoms and signs did not differ appreciably from those observed in venous thromboses resulting from other causes. Two of these 3 patients eventually recovered.

Associated Nontularemic Conditions.—These are summarized in table 3. All of the patients except 1 with serologic evidences of syphilis had repeated serologic examinations of the blood during hospitalization and none were found to become negative as the tula-

TABLE 1.—Seven Cases of Oculoglandular Tularemia.

Case	Age	Color	Sex	Contact	Incubation Period	Adenitis	Agglutinations	Days of Hospitalization	Complications or Coexisting Disease	Outcome
1	35	C	♂	Rabbit	2 days	Generalized	1:320 on 14th day	Died on 3d day	Pneumonia (tularemic ?)	Died on 14th day; autopsy showed right lobar pneumonia and generalized node enlargement; guinea pig inoculation reproduced lesions in 4 days
2	17	W	♂	Rabbit	6 days	Preauricular, parotid, submaxillary, cervical	Negative on 8th day 1:50 on 12th day 1:200 on 14th day	38	None	Recovery
3	20	W	♂	Mashed tick between fingers	9 days	Preauricular, cervical	1:320 on 15th day 1:640 on 24th day	105	None	Recovery
4	17	C	♂	Rabbits	2 days	Preauricular parotid, cervical	1:320 on 20th day 1:640 on 26th day 1:5,120 on 32d day	Deserted on 14th day	..	No follow-up record
5	25	C	♀	Rabbits	Multiple exposure	Parotid, submaxillary, cervical	Negative on 7th day 1:160 on 14th day 1:640 on 22d day	47	Syphilis, latent	Recovery
6	25	W	♂	Rabbit	5 days	Parotid, preauricular, submaxillary, cervical	1:640 on 23d day	59	None	Recovery
7	25	W	♀	Rabbit	Preauricular, parotid, cervical	Negative on 11th day 1:200 on 17th day	31	None	Recovery

It can be seen from table 2 that the incidence of pneumonia is much greater in the typhoidal type of tularemia than in other types. Twelve of our 21 patients with tularemic pneumonia died, a mortality rate of 57 per cent.

TABLE 2.—Pneumonic Involvement in Various Types of Tularemia

Ulcero-glandular.....	121	13	7.1
Oculoglandular.....	7	0	0
Glandular.....	25	0	0
Typhoid.....	14	8	57

Central Nervous System Involvement.—Several instances of stupor, meningismus and other signs of possible central nervous system involvement were noted among our patients. One colored male was found to have tularemic meningitis at autopsy. Another patient, a white boy 10 years of age, developed stupor and stiffness of the neck during the course of his disease.

2. Stuart, B. M., and Pullen, R. L.: Tularemic Pneumonia: Review of American Literature and Report of 15 Additional Cases, *Am. J. M. Sc.*, to be published.

remic infection ran its course. Only 1 of the 5 patients with recognizable heart disease failed to recover, and this patient, a white female, also had tularemic pneumonia and severe diabetes mellitus. Three pregnant women contracted tularemia, 1 at three months, 1 at four months and 1 a week before term. All gave birth to apparently normal children. Two patients with secondary pneumococcal pneumonia died, sputum typing

LABORATORY DATA

Although the history of animal contact and the clinical picture of the disease process usually permits the presumptive diagnosis of tularemia, laboratory data are necessary for confirmation and in some instances for establishment of the diagnosis.

Blood Changes.—A mild secondary anemia was observed frequently, the red cell count ranging from 3,500,000 to 4,000,000 per cubic millimeter. The average leukocyte count of 159 patients in whom total white blood cell counts were determined was 11,200. The average differential leukocyte count of 149 patients disclosed 70 per cent polymorphonuclear cells, 25 per cent lymphocytes and 5 per cent monocytes. The highest leukocyte count, a value of 90,000, was observed in a colored male who developed typhoidal tularemia twenty-four hours after cleaning rabbits and died thirty-six hours after the onset of the disease. Autopsy revealed no evidences of primary blood disease. The lowest leukocyte count in our series was 2,000, although 4 other patients were found to have white counts of less than 5,000 cells. One of these patients, a colored female, apparently had a malignant neutropenia following sulfonamide therapy.³

Urinalysis.—Excluding those patients found to have chronic renal disease, there were 14 instances of transient albuminuria which cleared as the acute phases of the disease subsided.

Agglutinations.—Specific agglutinins invariably appeared in all of our cases except in 9 instances in which the diagnosis was established by postmortem study, laboratory animals being inoculated in each of these instances. The agglutinins were absent during the first week of the disease but were demonstrated in titers of 1:40 to 1:320 in 213 of 216 cases during the second week. Agglutinins appeared on the fifteenth, eighteenth and twentieth days of illness in the remaining instances. Usually during the third week an abrupt rise in the agglutinin titer was observed, while the maximum titers of 1:1,280 to 1:10,240 were reached during the fifth or sixth week of the disease.

Several patients returned to the hospital because of other illnesses after recovering from tularemia. One patient was found to have an agglutinin titer of 1:320 seven years after recovery.

Blood Cultures.—Routine blood cultures were taken at the onset of the disease in 104 of our series of 225 cases. As the mediums in most instances consisted of plain agar or broth, these cultures were persistently negative. It is regrettable that direct inoculation of the patient's blood on fresh blood-glucose-cystine agar was performed in only 3 instances. In each a growth of *Bacterium tularensis* was obtained during the first ten days of the patient's illness.

Microscopic Examination of Lymph Node Biopsies.—Four patients were subjected to lymph node biopsy before tularemia was suspected. In each instance the examining pathologist suggested the diagnosis from the microscopic appearance of the excised tissue which was subsequently confirmed by positive agglutination tests.

Skin Tests.—Foshay's antiserum was used in performing skin tests in 13 instances. Eleven of these were interpreted as positive or doubtfully positive, while 2 failed to produce any reaction. Three patients developed local necrosis at the site of the cutaneous

injection. The 2 negative reactors were tested on the fourth and seventh days respectively.

Autopsies.—Seventeen patients in our series died of tularemia and 12 of these were submitted to postmortem examinations. Four of the autopsies have been previously reported by other investigators.⁴ In addition to the microscopic examination, the diagnosis of tularemia in these cases may be summarized as follows: 4 were diagnosed by agglutination tests before death, 2 by aspiration of material from the lungs and inoculation into laboratory animals, and 1 by the clinical features of a primary ulcer and regional lymphadenopathy. Patients subjected to autopsy have been summarized in table 4.

In the 5 patients that died and were not submitted to autopsy, the diagnosis of tularemia was confirmed in 4 by demonstrating specific agglutinins in the blood in titers of 1:200 to 1:1,280, while B. tularensis was cultured from the patient's blood of the sixth on a medium of fresh blood-glucose-cystine agar.

COURSE OF TULAREMIA

Treatment.—No specific therapy in our hands has proved to be consistently beneficial in the treatment of tularemia. Specific immune serum, according to Foshay,⁵ is effective in reducing the severity and duration of symptoms, especially when given early in the disease. Sulfonamides⁶ have been utilized as therapeutic agents but Ransmeier⁷ has shown B. tularensis to be resistant to sodium sulfadiazine experimentally in vivo. Heilman⁸ has recently reported an antibiotic substance (streptomycin) to be effective in treating experimental tularemia, an observation which needs further investigation. Little information concerning the effectiveness of penicillin against B. tularensis is available thus far, but it would appear to be of little value.

No therapeutic agent was consistently employed in the treatment of our series of patients. Sulfarsphenamine, neoarsphenamine, roentgen rays, infra-red rays, specific serum, human convalescent serum, acriflavine⁹ and the sulfonamides were all utilized during various intervals as systemic therapeutic agents. A critical analysis of the available records, however, indicates that these various agents had little if any influence on the course of the disease.

The local eye lesions were treated with wet boric acid compresses, strong protein silver, homatropine, hot saline soaks, 5 per cent solution of sulfathiazole and hot applications of half saturated aqueous magnesium sulfate with frequent lavage of the conjunctival sac with warm boric acid-saline solution. This latter form of treatment was apparently as effective as any other available therapeutic regimen.

Other local lesions were treated with 2 per cent saline compresses, boric acid soaks, magnesium sulfate soaks, roentgen rays, infra-red rays, acriflavine, 5 per cent sulfathiazole ointment, weakly saturated solution

of commercial urea and occasionally incision. Wet boric acid dressings or compresses saturated with magnesium sulfate solution seems to be the treatment of choice for local lesions.

The involved lymph nodes were seldom incised unless definite evidence of suppuration was present. Warm wet soaks of boric acid or saturated aqueous solution of magnesium sulfate apparently afforded the most relief of pain due to the buboes. In 47 cases (22.2 per cent) the glands eventually suppurated and either ruptured spontaneously or were incised when they were pre-

illness for the majority of the patients, as 15 deaths occurred during the first twenty days and several patients deserted the hospital early in their illness. A more reliable figure is probably higher than the actual one. The longest period of hospitalization for one patient was one hundred and forty-four days. Certainly the duration of hospitalization is an appreciable factor in consideration of the care of patients with tularemia.

Duration of Symptoms.—Excluding 6 patients that deserted the hospital and 17 patients that died with tularemia, the known duration of symptoms for the

TABLE 4—Summary of Seventeen Deaths from Tularemia

Case	Age	Sex	Color	Type of Disease	Contact	Associated Findings	Course of Illness	Duration of Illness	Blood Counts on Admission	Hospital Days	Presumptive Cause of Death

* Previously reported by Moss and Weilbacher² and by Weilbacher and Moss.⁴

sumably sterile. Incision and drainage of an enlarged gland in the neck of 1 patient resulted in death, apparently as a result of rapid dissemination of the organisms throughout the body following this procedure.¹⁰ It is our practice to withhold surgical intervention of inflamed lymph nodes until suppuration has occurred and rupture is imminent.

Average Hospital Days.—The average hospitalization for our patients was 22.35 days. This value is not entirely indicative of the actual duration of acute

remaining 202 patients in our series was 40.29 days. A substantial number, however, experienced malaise well beyond the average of forty days, the longest duration in 1 patient being one hundred and fifty-one days. These data concerning the length of convalescence should not be accepted as entirely accurate other than to emphasize again the prolonged morbidity of tularemia infections. Several of our patients failed to experience a complete sense of well being for almost a year following apparent clinical recovery.

Deaths.—Seventeen of 225 patients died with tularemia, a mortality of 7.55 per cent. These have been summarized in table 4. Twelve were colored and 5

10. Muecke, J. H., and Cannon, H. I.: Tularemia, in Piersol, G. M.; Britz, L. L., and others: *The Cyclopedia of Medicine, Surgery, and Specialties*, Philadelphia: J. A. Davis Company, 1940, vol. 15, pp. 430-447.

were white; 9 were males and 8 were females. As previously reported,² it has been our impression that Negroes manifest less resistance to tularemia than white patients, particularly to the pneumonic forms of the disease. This is further substantiated by the fact that 12 of 93 Negroes (12.9 per cent) died, while only 5 of 132 white patients (3.8 per cent) failed to recover from the disease. The average age of our patients that died was 33.8 years.

As one would expect, the mortality rates for the various types of tularemia varied considerably. Thus, 8 of 181 patients with ulceroglandular tularemia died, a mortality rate of 4.4 per cent, as compared to 7 of 14 patients with the typhoidal type of disease, a mortality rate of 50 per cent. One of 7 oculoglandular patients and 1 of 23 patients with glandular tularemia died, a mortality of 14.3 per cent and 4.35 per cent respectively. The average duration of the disease before death was 30.85 days. However, when 2 examples of chronic progressive tularemic infection were excluded from this group, the average duration of the disease before death was only eight days. The longest duration for the entire group was one hundred and sixty-seven days, while the shortest duration of illness before death was thirty-six hours.

Apparently most of the patients died as a result of their tularemic infection. Ten of the 12 patients examined post mortem had tularemic pneumonia and 1 also had tularemic meningitis¹¹ as well. Only 2 of the 12 patients examined post mortem failed to show widespread tularemic infection as evidenced by involvement of the liver, spleen and lymph nodes. Whether septicemia, toxemia or an unrecognized complication contributed to these patients' deaths we are unable to say. Three of the deaths in our group could be accounted for by complicating factors. One death was that of a white female which followed a blood transfusion reaction. Uncontrolled diabetes mellitus contributed to the death of another white woman. One colored female apparently developed a malignant neutropenia following sulfonamide therapy.

COMMENT

From the variety of clinical manifestations that have been noted, it is evident that the diagnosis of tularemia may frequently be fraught with difficulty. Although it is convenient to classify the disease into ulceroglandular, glandular, oculoglandular and typhoidal forms as proposed originally by Francis,¹² the clinical features of the various types may be quite similar. One may, in effect, consider tularemia a systemic disease in which the local ulceration with regional lymphadenopathy generally predominates but in which constitutional symptoms may appear which are out of proportion to the local lesion. The latter expressions of the disease are due to both a septicemia and a bacteremia. In such instances recourse to laboratory methods must be made to establish the diagnosis.

SUMMARY

An analysis of 225 cases of tularemia observed in a single institution has emphasized the wide variety of clinical expressions of tularemic infections. The prolonged morbidity and the case fatality rate (7.55 per cent) for this series also are worthy of note.

CONTROL OF SYPHILIS IN PREGNANT WOMEN

UNDER THE CARE OF THE GENERAL PRACTITIONER

HERMAN M. SOLOWAY, M.D.
CHICAGO

Several years ago I¹ described a plan for controlling syphilis in pregnant women under the care of the general practitioner. This plan, part of the Illinois statewide venereal disease control program (Chicago excluded), has been carried out along the general principles then outlined up to the present time, when I am able to report on the outcome of 1,448 cases of syphilitic pregnant women under the care of 1,087 private physicians. McKelvey and Turner,² McCord,³ Ingraham,⁴ Halloran⁵ and others⁶ have reported on the outcome of syphilitic pregnant women treated in public hospital clinics and maternity centers, but I have been unable to find any reports of the outcome of such cases treated by private physicians.

PLAN OF MANAGEMENT

The Illinois antepartum blood-testing law became effective in July 1939. This law provides that all physicians attending pregnant women must submit specimens of the patients' blood for serologic examination to a state or an approved private or hospital laboratory. In the case of a positive blood test, a copy of the report is submitted by the laboratory to the office of the Division of Venereal Disease Control. The central registry is then checked to see if the case has been reported by the physician. If it has not been reported, a letter is sent to the attending physician requesting him to report the case if he has determined that the patient has syphilis. On receipt of this report, antisyphilitic drugs are sent to the physician together with the pamphlet "Syphilis in Mother and Child," published by the United States Public Health Service. The physician's morbidity venereal disease report is then carefully checked as to the age of the patient, sex, color, approximate date of delivery, duration and type of syphilitic infection and whether or not the patient is receiving treatment. If the patient is not receiving treatment, a venereal disease investigator, nurse or public health physician gets in touch with the patient, with the approval of the attending physician, and every effort is made to place and keep her under treatment throughout her term of pregnancy. Another letter is then sent to the attending physician informing him of our special interest in the case, at the same time calling his attention to the importance of instituting treatment promptly and continuing it until the day of delivery. He is also urged to make a test of the infant's blood after two months. An average of 1,462 letters yearly sent to physicians discussed some phase of the management of the syphilitic pregnant women under their care.

From the Illinois Department of Public Health, Dr. Roland R. Cross, director. Mr. Benjamin H. Sklar compiled the statistical data. Dr. Soloway was formerly chief, Division of Venereal Disease Control, Department of Public Health.

MATERIAL STUDIED

This report is concerned with the outcome of 1,448 cases of syphilitic pregnant women, all under the care of private physicians. No clinic treated cases were included. Only those cases were analyzed in which the child's blood serologic status was rechecked after 2 months of age. There were 243 women who were not included in this study for the following reasons: 57 moved out of the state; 76 moved and could not be located; 56 were transferred to venereal disease clinics; 46 refused to have their children blood tested; 5 moved to the city of Chicago, and there were 3 cases in which the attending physicians refused to make blood tests of the children. There were reported an average of 350 cases a year under the care of 300 individual physicians.

ANALYSIS OF THE CASES STUDIED

Color.—There were 1,294 white and 154 colored pregnant syphilitic women studied (table 1).

Age.—There were 613 women between the ages of 15 and 24 years, 592 between 25 and 34 years and 162 over 35 years old. The age of 47 women was unknown (table 1).

Stage of Syphilis.—There were 16 cases of primary syphilis, 100 cases of secondary syphilis, 737 cases of asymptomatic syphilis of less than four years, 464 cases of late syphilis, 57 cases of congenital syphilis, 5 cases of neurosyphilis and 2 cases of cardiovascular syphilis. In 67 cases the stage of syphilis was not stated (table 2).

PLAN OF TREATMENT

A prescheduled outline of treatment is also mailed to the attending physician. This plan of treatment provides for a weekly intramuscular injection of a heavy metal without interruption throughout the term of pregnancy and eight to ten weekly injections of an arsenical drug with an occasional four weeks rest period. It is recommended that the treatment scheme be so arranged that the arsenical drug is administered in the last weeks of pregnancy. The drugs that are made available to the physician without cost are neo-arsphenamine (0.3 to 0.6 Gm.), oxophenarsine hydrochloride (mapharsen) or clorarsen (0.045 to 0.067 Gm.), bismuth salicylate (0.2 Gm.) or potassium bismuth tartrate (0.2 Gm.).

The physician is cautioned to make a complete physical examination and urine analysis and to observe carefully any untoward reactions from treatment, particularly early damage to the liver or kidneys. He is advised also to check on the outcome of the pregnancy, with special attention to the placental microscopic examination, roentgenograms of the infant's long bones, blood test after two months and periodic pediatric examinations for at least six months.

AMOUNT OF TREATMENT RECEIVED

There were 355 women who did not receive any anti-syphilitic treatment at all; 349 received from one to nine intravenous injections of an arsenical and 403 received one to nine intramuscular injections of a bismuth preparation; 423 received from ten to nineteen arsenical injections and 367 received ten to nineteen

bismuth injections; 215 received twenty to twenty-nine arsenical injections and 202 received the same amount of bismuth; 64 women received more than thirty arsenicals and 79 women received more than thirty injections of bismuth preparations. The amount of treatment received by 42 women was not stated (tables 3 and 4).

RESULTS OF TREATMENT

The treatment of the pregnant syphilitic woman to prevent her infant from becoming infected in utero is one of the most effective forms of preventive medicine known. It has also been our experience that the sooner syphilis is diagnosed and the earlier the treatment is begun and continued throughout pregnancy, the better the prognosis for a living nonsyphilitic child.⁷

In the 550 cases in which treatment was started before the end of the fourth month of pregnancy there were 518 (94.31 per cent) normal nonsyphilitic children, and 32 cases terminated in stillbirth, miscarriage

[illegible]

Case holding report form.

or a syphilitic infant. In the 134 cases in which treatment was begun before the end of the fifth month of pregnancy there were 112 (83.58 per cent) normal non-syphilitic children, and 22 cases terminated disastrously.

There were 409 cases of syphilitic pregnant women placed under treatment after the fifth month, of which number 207 (50.6 per cent) terminated in the birth of normal nonsyphilitic children and 202 (49.4 per cent) terminated disastrously.

There were 355 cases of syphilitic pregnant women in which no treatment was given and among these only 93 (26.48 per cent) terminated in the birth of normal nonsyphilitic children, while the outcome of 262 (73.52 per cent) of the pregnancies in this group were disastrous (table 5).

REACTIONS TO TREATMENT

It is difficult to make an accurate analysis based on the reports of 1,087 individual observers. It is particularly difficult because the observers were all general

7. Cole, H. N., and others: Cooperative Clinical Studies in Treatment of Syphilis: Syphilis in Pregnancy. Ven. Dis. Inform. 15:83 (March) 1934; 17:39 (Feb.) 1936.

practitioners, most of them with limited experience in the field of syphilotherapy; then too the reactions encountered in the treatment of syphilis by chemotherapy are varied in kind and degree and are subject to a wide latitude in their interpretation.

There was 1 case of cutaneous hemorrhage reported, 1 of shock, 1 of jaundice and 2 of extensive dermatitis

(type not described), all of them presumably serious reactions to treatment. The remainder consisted of bothersome but unimportant side effects such as nausea, vomiting, Herxheimer reactions and dizziness. It is particularly notable that there was not a single fatality encountered in the group; and there were but 8 reports of "severe" reactions, the nature of 13 other "severe" reactions being mentioned but the nature not recorded. It would seem, therefore, that pregnancy does not add to the hazards of antisyphilitic treatment—an opinion about which there is some difference of opinion.

CASE HOLDING

A very important part of the control of syphilis in pregnant women is the need to keep them under treatment throughout the pregnant period. To effect this there is sent to each attending physician a monthly check-up letter, which serves also as a requisition for free antisyphilitic drugs. It also suggests the next

five weeks treatment for the patients listed in our records as being under the care of the physician addressed. He is requested to indicate his choice of drugs for each patient and at the same time to report any patient who has discontinued treatment. Every effort is made by an investigator, nurse or public health physician to return the delinquent patient to the reporting physician for further treatment. We are thus

able to have a thirty day report from physicians receiving free drugs of every patient under their care. An average of 740 such investigations were made each year in order to have about 300 cases reported, placed and kept under treatment throughout pregnancy as well as to check the child's blood after 2 months of age.

COMMENT

There are still many undesirable factors to overcome. There are still some practitioners who are not convinced of the desirability to do routine blood tests for syphilis on all pregnant women.

Many physicians have written to us of their inability to take blood specimens from infants, and they have asked for assistance. In such instances the child is referred to a venereal disease clinic, or a staff physician is sent to take the blood.

* Information as to the stage of syphilis was not obtained because of death or military service of the attending physician or of our failure to locate the patients.

The Illinois Prenatal Law provides for the blood test to be taken by the attending physicians at the time of the patient's first visit, with the intent of instituting treatment early. Yet to this day many pregnant women do not apply for medical care until very late in pregnancy or just before confinement. Then too the law does not compel a woman to take treatment if she refuses it.

Another important handicap to overcome is the reluctance of many mothers to have their infants' blood tested.

There is still much difficulty in remote rural districts in securing the cooperation of midwives in our plan to control syphilis in pregnant women.

Obviously there is great need for continued educational programs on all phases of the cause, spread and cure of syphilis. The general public and the midwife must be educated, and the general practitioner is in need of special education.

CONCLUSIONS

1. The treatment of pregnant syphilitic women to prevent congenital syphilis is one of the most effective forms of preventive medicine.

2. The treatment recommended consists in a weekly muscular injection of a bismuth compound throughout the term of pregnancy and eight to ten intravenous injections of an arsenical, with an occasional four week rest period.

TABLE 5.—Results by Time of Treatment

Month Treatment Started	Total	Normal Results	Disastrous Results*	Per Cent Normal	Per Cent Disastrous

* Disastrous result indicates miscarriage, stillbirth or living syphilitic infants.

3. As a result of the Illinois plan of control of syphilis in pregnant women under the care of the general practitioner there were 94.31 per cent normal living nonsyphilitic children in the 550 cases in which treatment was started before the end of the fourth month of pregnancy.

4. There was not a fatality reported as the result of antisyphilitic treatment.

5. Interpretation of serious treatment reactions by so many general practitioners* (with limited experience in this field) is very difficult. There were 8 "serious" reactions reported, and mention was made of 13 other "serious" reactions which were not recorded.

6. Pregnant women tolerate antisyphilitic treatment as well as if not better than nonpregnant women.

7. Case holding efforts necessitated public health physicians, nurses and lay investigators to make 740 investigations every year in order to have about 300 cases

THE TREATMENT OF ACUTE SUPPURATIVE OTITIS MEDIA WITH PENICILLIN

LOUIS WEINSTEIN, M.D., Ph.D.

AND

HILTON B. ATHERTON, M.D.

BOSTON

Acute suppurative otitis media is a problem of great importance to the pediatrician, internist and otologist who encounter it frequently either as an isolated disease or in the course of such infections as scarlet fever or measles. If improperly or inadequately treated, its complications may lead to partial or total loss of auditory function or, in some instances, may seriously endanger life. The development of a method of treatment which will eliminate serious complications and reduce the incidence of mastoidectomy and other operative procedures is most desirable and is a matter which has attracted the attention of many investigators for a long time.

Before the era of specific chemotherapeutic agents, therapy of acute suppurative otitis media was directed mainly to the local application of various agents through the external auditory canal for the purpose of reducing pain and killing the bacteria that were present in the middle ear. Such methods had but little beneficial effect, and a high percentage of serious complications attested this fact. The discovery of the sulfonamides led to the use of this group of chemicals not only for the treatment of the suppurative otitis media but also as prophylactic agents for the prevention of this condition in scarlet fever, measles and so on. The sulfonamides have appeared to be of little value in the prevention of infections of the middle ear during the course of other diseases, according to some investigators.¹ Their use after the otitis media has been established has led to variable results. Some cases have responded well, with complete subsidence of the acute process and without involvement of the mastoid. In others, aural discharge has ceased shortly after one of the sulfonamides was administered but recurred in a short time after the drug had been stopped. Even repeated treatment of some patients has not produced complete eradication of the infections, and many of them have developed mastoiditis. Treatment of repeated recurrences until ear discharge ceased has led to delay of mastoidectomy in some cases until the otitis media became chronic and the only hope of cure was a radical operation with subsequent loss of hearing on the affected side. In some instances, treatment with one of the sulfonamides has had no effect on the usual course of the ear infection and operation has been resorted to after the usual period of waiting. While the results of treatment of purulent otitis media with sulfonamides are not universally good, the use of these drugs has improved the situation decidedly, since a fairly large number of cases have been cured without any further treatment and, on the whole, the incidence of serious complications has decreased; suppurative mastoiditis.

This work was aided by a grant from the Johnson Research Foundation, New Brunswick, N. J.

From the Haynes Memorial and the Evans Memorial Massachusetts Memorial Hospitals, and the Department of Medicine, Boston University School of Medicine.

The penicillin was provided by the Office of Scientific Research and Development from supplies assigned by the Committee on Medical Research for clinical investigations recommended by the Committee on Chemotherapeutic and Other Agents of the National Research Council.

lateral sinus thrombosis, extradural abscess, bacteremia and other conditions may occur, however, in patients who are treated with one of the sulfonamides. Although these drugs have been of tremendous aid in the treatment of suppurative otitis media, they still leave much to be desired.

The agent which has attracted the most attention recently in the treatment of infectious diseases of various types is penicillin. No attempt to review the literature concerned with the development of this antibiotic substance or with its use in various bacterial diseases will be made here, since this subject has been adequately covered in many publications. As soon as the highly bactericidal and nontoxic properties of penicillin were clearly demonstrated, investigations were started to determine its usefulness in the treatment of infections affecting the ear, nose and accessory structures. Only those reports dealing with the application of the antibiotic substance in acute purulent otitis media are reviewed in this paper.

Swanson and Baker² treated 14 cases of acute suppurative otitis media with varying doses of penicillin, with universally successful results. The drug was administered intramuscularly and the amount used varied according to the severity of the case; total dosage ranged from 360,000 to 1,140,000 units. Infections due to *Staphylococcus aureus* were found to require more penicillin before a cure was produced than those in which the hemolytic streptococcus or other organisms were concerned. A study of the bacteriology of the aural discharges revealed *Staph. aureus* in 2 cases, hemolytic *Staph. aureus* in 2, the hemolytic streptococcus in 8, the pneumococcus in 1 and hemolytic *Staph. aureus* combined with the beta-hemolytic streptococcus in 1.

Glassburn³ has reported 3 cases of acute suppurative otitis media in which facial paralysis occurred as a complication on the sixth, fifteenth and twenty-third day of the ear infection. One of these was treated with sulfadiazine and the 2 others with penicillin given intramuscularly in divided doses varying from 100,000 to 160,000 units daily. All the patients recovered completely, and no surgical procedures were necessary.

The effect of penicillin on acute suppurative otitis media has also been studied by Ball.⁴ Seventeen cases, 12 of which occurred as a complication of scarlet fever, were first treated with full dosage of sulfadiazine and, when this agent was found to be ineffective, 20,000 units of penicillin was administered intramuscularly every four hours until a total of from 380,000 to 2,000,000 units had been given. Resolution of the infection with normal hearing resulted in one to two weeks, the average time being about nine days. Ten of the post-scarlet fever patients recovered rapidly, 1 required surgical intervention and the last got well slowly. Clouding and destruction of the mastoid cells were noted by x-ray examination in all of the patients. Mastoiditis was a clinically evident complication in all at the time of starting the penicillin therapy, since mastoid tenderness and/or sagging of the posterior wall of the auditory canal was evident at the end of the ineffective course of sulfadiazine. The other 5 patients with otitis media who had signs and symptoms of acute mastoiditis at the termination of the sulfonamide treatment were given penicillin, and all recovered com-

pletely without any further measures. Bacteriologic studies of the aural discharges in these patients revealed hemolytic *Staphylococcus albus* in 4 and *Staphylococcus aureus* in 1.

Craig and his co-workers⁵ have reported the results of penicillin treatment of 36 cases of acute suppurative otitis media and acute mastoiditis. Their original scheme of treatment consisted in the continuous intravenous administration of the antibiotic agent in isotonic solution of sodium chloride containing 20,000 units per liter. Intramuscular injections of the drug, 10,000 units every three hours for seven days, also were given. The treatment schedule was eventually changed to 20,000 units administered intramuscularly either in separate doses every two hours or continuously for at least five to seven days. All of the patients responded satisfactorily; those in whom the otitis media was early were rid of the infection after two to four days of treatment, while those who had had infections of the middle ear for one to two weeks prior to start of treatment required a longer period of therapy before good results were obtained.

Our purpose in the work reported here was to investigate the effectiveness of penicillin given very early in the course of suppurative otitis media in curing the infection and preventing complications; to determine the effective dose range and the length of time over which treatment had to be continued; to ascertain whether or not there is any correlation between the total amount of the antibiotic substance required to produce good results and the type of organism which is responsible for the infection, and to study, by means of x-ray examinations, the effect of this type of treatment on involvement of the mastoid. Since purulent otitis media is not an infrequent sequel to scarlet fever, the opportunity was available in our hospital to treat a fairly large number of patients with acute middle ear infections and to follow them very carefully from the bacteriologic and clinical points of view.

METHODS

Patients in whom the diagnosis of acute suppurative otitis media was unquestionable were the ones selected for this study. No individual was treated until exudate appeared in the external auditory canal as the result either of spontaneous perforation (48 cases) or of paracentesis of the drum. As soon as purulent aural discharge appeared, cultures were taken in the manner to be described and treatment with penicillin started. This was the procedure for all but 11 of the patients; 5 were first treated twenty-four hours after the appearance of the exudate, and 6 did not receive the antibiotic agent until forty-eight hours after the eardrum had ruptured.

Ten thousand units of penicillin was administered by intramuscular injection every three hours until the external auditory canal was dry for at least twenty-four hours; in some instances treatment was prolonged for several days after cessation of aural drainage. The size of each dose and the interval between injections were kept constant, so that the only variable was the length of time over which therapy was continued. Each patient was examined daily from the time of first appearance of signs of acute suppurative otitis media for changes in appearance of the eardrum and for evidence of mastoiditis. The external auditory canal was cleansed

of purulent material several times a day by means of dry sterile gauze wicks.

Roentgenologic examination of the mastoid on the involved side was carried out in every case as soon as the ear began to drain and repeated every seven days, the last film being taken on the day before discharge from the hospital. In many of the cases an x-ray study of the paranasal sinuses also was made.

Four of the patients who developed secondary infections with gram negative bacteria were treated by the instillation of four drops of a sterile aqueous solution of 10 per cent urethane and 1 per cent sulfanilamide into the external auditory canal every three hours, the purulent exudate being first removed by means of sterile gauze wicks.

The aural discharge in all cases was obtained for bacteriologic study as soon as it was first observed, by inserting a sterile cotton swab gently into the external canal. This material was streaked immediately over a blood agar plate, the medium consisting of a mixture of yeast extract, tryptose, peptone, heart infusion, glucose and agar. All cultures were incubated at 37 C. for twenty-four to forty-eight hours and then the colonies examined macroscopically and by means of the Gram stain. All of the gram negative bacteria which were isolated were studied by means of sugar reactions and type of growth on eosin-methylene blue agar. Cultures of the auditory canal were taken daily as long as discharge persisted and about every other day thereafter until the patient was discharged from the hospital.

All of the cases were observed for a minimum of seven days following cessation of penicillin treatment. In most instances this period of observation was for two or more weeks because of the necessity of completing the quarantine period for scarlet fever. A follow-up study of the patients was made by means of a mailed questionnaire from one to eight months after discharge from the hospital.

RESULTS

Fifty cases of acute suppurative otitis media, 48 occurring as a complication of scarlet fever, 1 observed in the course of measles and another during an episode of streptococcal pharyngitis, were studied. Perforation of the tympanic membrane with discharge of purulent exudate took place between the first and the fifth day of the primary disease in 15, between the eighth and fifteenth day in 14, between the sixteenth and twenty-fifth in 14, and between the thirtieth and sixtieth days in 7 patients. Treatment with penicillin was started in 39 of the cases on the same day on which ear drainage was first noted, in 5 after twenty-four hours and in the remaining 6 forty-eight hours following the first appearance of exudate in the external auditory canal.

Bacteriologic studies of the purulent exudates revealed hemolytic *Staphylococcus aureus* alone in 11 cases (22 per cent), the beta-hemolytic streptococcus alone in 21 (42 per cent), nonhemolytic *Staph. aureus* alone in 10 (20 per cent), the beta-hemolytic streptococcus and hemolytic *Staph. aureus* in 5 (10 per cent), the beta-hemolytic streptococcus and nonhemolytic *Staph. aureus* in 2 (4 per cent) and *Corynebacterium diphtheriae* and nonhemolytic *Staph. aureus* in 1 (2 per cent). After the use of penicillin for varying periods of time, these organisms tended to disappear fairly rapidly in most instances, but *Staphylococcus aureus* persisted for a considerably longer time than did the beta-hemolytic streptococcus.

Penicillin was administered to each of the patients in a dosage of 10,000 units intramuscularly every three hours and treatment continued until the aural discharge had been absent for at least twenty-four hours. Thus, as already pointed out, the daily total dose for each patient was the same, differences in the amount of antibiotic substance used being determined only by the duration of the therapy. Twenty-two patients were treated for an average of four days with a total of between 300,000 and 400,000 units of penicillin. Thirteen of these were infected with *Staphylococcus aureus* alone, 4 with the beta-hemolytic streptococcus and hemolytic *Staph. aureus*, 3 with nonhemolytic *Staph. aureus* alone, 1 with hemolytic *Staph. aureus* alone and 1 with hemolytic *Staph. aureus* and the beta-hemolytic streptococcus. The average time required for the aural discharge to disappear was 3.9 days. There were four recurrences of the suppurative otitis media after completion of treatment in this group.

Nineteen patients required a total dose of between 400,000 and 800,000 units of penicillin, administered

TABLE 1.—Summary of Bacteriologic Findings and Clinical Results in the Treatment of Acute Suppurative Otitis Media with Penicillin

	Total Dosage of Penicillin Used			
	300,000-400,000 Units	400,000-800,000 Units	800,000-1,500,000 Units	1,500,000-2,500,000 Units
Number of patients.....	22	19	8	1
Average number of days treated.....	4	6.6	14.2	33
Average time required for dry ear.....	3.9	4.4	14.0	30
Number of recurrences.....	4	1	3	0
Hemolytic <i>Staphylococcus aureus</i> alone.....	1	6	4	0
Hemolytic streptococcus alone	1	4	1	0
Nonhemolytic <i>Staphylococcus aureus</i> alone.....	3	7	0	0
Hemolytic streptococcus and hemolytic <i>Staphylococcus</i>	4	0	0	1
Hemolytic streptococcus and nonhemolytic <i>Staphylococcus aureus</i>	1	1	0	0
Nonhemolytic <i>Staphylococcus aureus</i> and <i>Corynebacterium diphtheriae</i>	0	1	0	0

over an average period of 6.6 days, to produce disappearance of the signs of infection of the middle ear in an average of 4.4 days. Of these individuals, 6 were found to harbor *Staphylococcus aureus* alone, 4 the beta-hemolytic streptococcus alone, 7 nonhemolytic *Staph. aureus*, 1 the beta-hemolytic streptococcus and nonhemolytic *Staph. aureus* and 1 nonhemolytic *Staph. aureus* and *C. diphtheriae* in the aural exudate. There was one recurrence of otitis media following cessation of therapy in this group.

Eight of the 9 remaining patients were given between 800,000 and 1,500,000 units of the antibiotic agent over an average period of fourteen and two-tenths days; the mean time required for the disappearance of signs of infection of the ear was fourteen days. Bacteriologic studies of the aural discharges in these individuals revealed 4 to contain hemolytic *Staphylococcus aureus* alone, and the other 4 the beta-hemolytic streptococcus alone. There were three recurrences in this group. The ninth patient, who was infected with the beta-hemolytic streptococcus and hemolytic *Staph. aureus* was treated with 2,500,000 units of penicillin over a period of thirty-three days; the aural discharge stopped thirty days after therapy was started. The summarized data are shown in table 1.

Daily examinations of the ears while treatment was being given revealed gradual decrease in the amount of purulent exudate and subsidence of bulging and redness of the drum. The temperature, if elevated, returned rapidly to normal. In some instances slight to moderate inflammation of the tympanic membrane as well as a very small amount of mucoid material in the external auditory canal persisted for several days after treatment was stopped. Many of the patients showed some degree of thickening of the eardrum at the time of discharge from the hospital.

Correlation of the type of organisms producing the purulent otitis media and the total dosage of penicillin required to effect a cure revealed that in the group of 22 patients recovering after treatment with the smallest amount of penicillin (300,000 to 400,000 units) only 9 (41.4 per cent) were infected with *Staphylococcus aureus*, hemolytic or nonhemolytic, either alone or in combination with the beta-hemolytic streptococcus. Of the 19 patients requiring somewhat larger doses (400,000 to 800,000 units), 15 (78.9 per cent) harbored *Staphylococcus aureus* either alone or in combination with the beta-hemolytic streptococcus. Four (50 per cent) of 8 subjects who had to be given between 800,000 and 1,500,000 units of penicillin before there was a cessation of the signs and symptoms of disease of the middle ear were infected with the hemolytic *Staph. aureus* alone. The individual who required the largest

thickening and grayness of the wall of the lateral sinus, and a diagnosis of sinus phlebitis was made. There were no clinical signs of mastoiditis before carrying out the surgical procedure, and it is important to point out that no evidence of infection of the mastoid bone on the affected side could be found at operation. Two other patients developed elevations of temperature, in 1 case to 102-103 F. for three days, while receiving treatment. The fever disappeared very promptly when administration of the drug was stopped, and it was assumed that the febrile reaction was the result of an allergic reaction to penicillin. No other complications were observed.

Recurrences of the otitis media at various times after cessation of penicillin treatment were observed in 8 patients. Of these, 4 were in the group who had received 300,000 to 400,000 units of drug in the original course; 1 developed a recurrence of the infection twice. One course of treatment failed to produce a permanent cure in 1 patient in the group that had received 400,000 to 800,000 units of penicillin and in 3 among those who had been given 800,000 to 1,500,000 units. Of the latter, 1 patient had to be given three courses of therapy with the antibiotic agent before he remained free from ear infection. Thus, a total of 8, 16 per cent, of the patients had recurrences; 2 of these, 4 per cent, had more than one recurrence. Three of the recurrences of infection occurred in five days, 1 in eight days, 2 in twenty-two days and 1 in thirty-two days after cessation of penicillin treatment. Bacteriologic studies revealed that, in most instances, recurrence of disease of the middle ear took place in those who had been infected with *Staphylococcus aureus* alone or in combination with the beta-hemolytic streptococcus during the first episode of suppurative otitis media; in many cases these organisms were still present in the external canal in spite of the absence of purulent exudate when penicillin therapy was stopped. All recurrent attacks were treated with penicillin in various doses. The results of this therapy are shown in table 2. From these data it can be seen that in 4 instances cure resulted after three to six days of treatment during which a total of 230,000 to 450,000 units of penicillin was given. Four other patients required 500,000 to 800,000 units of drug administered over a period of seven to nine days to produce a beneficial effect. Two were injected with 800,000 to 1,000,000 units of penicillin during eight to ten days before they recovered. The time required for cure of the exacerbations of the middle ear infections appeared to be in the same order of magnitude as that necessary to produce cessation of aural discharge during the first attack. All of the patients were completely free from all signs and symptoms of otitis media when they were discharged from the hospital.

A follow-up study carried out by mail revealed that 2 patients had had recurrences of the aural discharge within the first six weeks after cessation of penicillin therapy. They were not seen by us but their parents reported that, in both instances, the infection subsided after a short course of treatment with one of the sulfonamides. One patient developed whooping cough some time after discharge from the hospital and, in the course of this disease, had otitis media from which he recovered in several days with no treatment. Three months after leaving the hospital a fourth subject had a recurrence of earache with a slight amount of discharge, which ceased after one application of "ear drops."

During the course of penicillin treatment, gram negative bacteria appeared in the purulent exudate in the ears of 4 of the patients. Table 3 indicates the time

TABLE 2.—Dosage of Penicillin Used in Treatment of Recurrences

Number of Recurrences Treated	Number of Days Treated	Total Dose of Penicillin Used, Units
4.....	3-6	230,000-450,000
4.....	7-9	500,000-800,000
2.....	8-10	800,000-1,000,000

quantity of penicillin (2,600,000 units) was found to be harboring the beta-hemolytic streptococcus and non-hemolytic *Staph. aureus* in the aural exudate. From these data it would appear that infections of the middle ear in which *Staphylococcus aureus* is one of the etiologic agents are, on the whole, more refractory to treatment with penicillin than those in which the beta-hemolytic streptococcus is the etiologic agent.

Daily physical and weekly roentgenologic examinations of the mastoid were carried out in every case. None of the patients had any clinical evidence of mastoiditis in the form of redness, swelling or tenderness over the mastoid bone or sagging of the posterior auditory canal wall. X-ray studies revealed clouding of the mastoid cells coincident with the first appearance of discharge from the ear in all of the cases. In many, a minimal to moderate degree of cell destruction was also noted at the time therapy was started and was still present when the patient was discharged from the hospital. In a few instances there appeared to be regression of the process in the mastoid during the course of penicillin treatment.

Three of the patients with acute suppurative otitis media who were treated with penicillin developed complications directly related to the disease of the middle ear while receiving treatment. Two of them had a right facial paralysis, peripheral in character, which gradually cleared. In the third, fever, stiff neck and a pleocytosis of the cerebrospinal fluid (1,000 lymphocytes per cubic centimeter) occurred during therapy with the antibiotic agent. Mastoidectomy revealed

elapsing between the inception of penicillin treatment and the appearance of the gram negative bacteria, the length of time over which these organisms persisted before treatment was started, and the response to the instillation of urethane-sulfanilamide mixture. Three of the patients were harboring *Proteus vulgaris* and 1

TABLE 3.—Results of Treatment of Gram Negative Ear Infections Occurring During the Course of Penicillin Therapy with Urethane-Sulfanilamide Mixture

Patient	Days Elapsing Between Beginning of Penicillin Treatment and Appearance of Gram Negative Bacteria	Days Elapsing Between Appearance of Gram Negative Bacteria and Start of Urethane Treatment	Dose of Urethane	Number of Days of Urethane Treatment	Time Required for Gram Negative Organisms to Disappear from Ear Discharge
B. B.	2	5	4 drops in ear every 3 hours	6	1
M. P.	3	17	4 drops in ear every 3 hours	7	2
T. R.	1	8	4 drops in ear every 3 hours	7	1
T. T.	4	19	4 drops in ear every 3 hours	7	1

Pseudomonas aeruginosa. All were treated with an aqueous solution of 10 per cent urethane and 1 per cent sulfanilamide every three hours in the manner described under Methods. In all cases the gram negative bacteria disappeared after one to two days of treatment and were never recovered in culture again during the remainder of the period of observation.

SUMMARY AND COMMENT

From the results obtained in this study, it appears that penicillin is a very effective agent in the treatment of acute suppurative otitis media in which gram positive cocci are the etiologic agents. While local therapy might be more effective in this disease because high concentrations of drug could be placed at the actual site of infection and the necessity of frequent intramuscular injections with the attendant discomfort eliminated, it is not feasible at present because of the difficulty of introducing the drug into the middle ear. The antibiotic agent has many advantages over the sulfonamides in the treatment of acute middle ear infections because of its lack of toxicity, its failure to be inhibited by exudates and the fact that its use leads to a greater percentage of permanent cures without the necessity of resorting to mastoidectomy. There appears to be a definite relationship between the amount of penicillin required to produce good results and the type of organisms which are producing the otitis media. The data given seem to indicate that those infections in which the hemolytic *Staphylococcus aureus* is present, either alone or in combination with the hemolytic streptococcus, are more difficult to treat and require larger doses of the drug before a cure is effected. While recurrences are seen after penicillin treatment, these are apparently easily controlled by readministration of the antibiotic substance with eventual complete eradication of infection in all cases. The recurrence rate in penicillin-treated patients is definitely lower than in those receiving the sulfonamides.

Complications of suppurative otitis media are reduced to a minimum, and mastoiditis, which is by far the most common of the sequelae following middle ear infection,

is almost completely eliminated by penicillin therapy. In the 1 patient in this study who required surgical intervention because of a lateral sinus phlebitis, there was no evidence of mastoid infections at the time of operation. Table 4 indicates the incidence of mastoidectomy following purulent otitis media at the Haynes Memorial Hospital during the last five and one-half years. From 1940 until the inception of penicillin, all cases of acute suppurative otitis media were treated with one of the sulfonamides, and 27 to 52 per cent of them required mastoidectomy.

In the eight months during which all patients with suppurative otitis media were treated with penicillin, only 1 (2 per cent) underwent mastoidectomy, and in this instance the operation was not performed for difficulty in the mastoid bone but because of development of lateral sinus phlebitis. This represents a thirteen to twenty-six fold decrease in the incidence of mastoidectomy as compared to the period in which the sulfonamides were in use.

In general, in otitis media occurring during the course of scarlet fever, x-ray examination of the mastoid on the involved side on the first day the aural discharge appears usually shows clouding of the mastoid cells and, in some cases, a slight degree of destruction in addition. This was also true in the case reported here, but there appeared to be no increase in the severity of the roentgenologic findings during or after completion of the course of penicillin treatment. In a few instances there was clearcut evidence that the infection in the mastoid bone regressed under therapy.

Gram negative organisms such as *Proteus vulgaris*, *Pseudomonas aeruginosa*, *Escherichia coli* and *Hemophilus influenzae* are known to be insensitive to the action of penicillin. Acute or chronic otitis media due to or complicated by infection with these bacteria is therefore not amenable to penicillin therapy. Collins and Hughes⁶ have recently pointed out the frequency and preponderance of gram negative organisms in chronic otitis media and the difficulty encountered in treating these cases with penicillin. They consider these bacteria to be true pathogens and not mere saprophytes. Weinstein and McDonald⁷ have shown that some of these organisms are very sensitive to the action of urethane in the test tube, and this drug was used to treat all of the patients in this study who developed secondary infections of the middle ear with

TABLE 4.—Incidence of Mastoidectomy in Suppurative Otitis Media at Haynes Memorial Hospital from 1940 to 1945

Year	Number of Cases of Otitis Media	Number of Mastoidectomies	Per Cent of Otitis Media Requiring Mastoidectomy

Proteus vulgaris or *Pseudomonas aeruginosa*. All responded quickly and completely to local instillation of a 10 per cent urethane-1 per cent sulfanilamide solution in water. Although the number of cases of otitis

6. Collins, E. C., and Hughes, K. E. A.: The Treatment of Chronic Suppurative Otitis Media by the Local Application of Penicillin and Other Drugs. *J. Laryng. & Otol.* **59**: 81-95, 1944.

7. Weinstein, L., and McDonald, A.: The Effect of Urea, Urethane, and Other Carbamates on Bacterial Growth. *Science* **101**: 44-45, 1945.

media in which gram negative bacteria were present is very small, the results obtained with local application of urethane-sulfanilamide solution are quite striking. Further study of this combination of drugs for use in chronic middle ear infections is warranted.

The following regimen of penicillin therapy for suppurative otitis media due to gram positive organisms has been instituted in the hope of eliminating the recurrences and reducing still further the incidence of complications: Immediately on appearance of purulent exudate in the external auditory canal, 15,000 units of penicillin is administered intramuscularly and the same dose repeated every three hours until the aural discharge has been completely absent for seventy-two hours.

CONCLUSIONS

1. Fifty cases of acute suppurative otitis media, 48 of which occurred as a complication of scarlet fever, were treated with varying doses of penicillin intramuscularly. The external auditory canal was free from exudate in 82 per cent of the patients in less than four and one-half days following institution of therapy. Recurrence of the infection was observed in 16 per cent; these responded well to treatment with larger doses of penicillin.

2. There appeared to be some degree of correlation between the total dosage of penicillin required to effect a cure and the type of organism producing the middle ear infection. Infections in which the hemolytic *Staphylococcus aureus* was present alone or in combination with the beta-hemolytic streptococcus seemed to be more resistant to therapy but responded to larger quantities of the antibiotic agent.

3. Complications of acute suppurative otitis media were reduced to a minimum, and mastoidectomy was only an infrequent necessity.

4. Secondary infections with gram negative bacteria were well controlled by the local administration of 10 per cent urethane and 1 per cent sulfanilamide in aqueous solution.

5. The following regimen is suggested for the treatment of acute suppurative otitis media: intramuscular administration of 15,000 units of penicillin immediately after the appearance of exudate in the external auditory canal and repetition of the same dose every three hours until the aural discharge has been completely absent for seventy-two hours.

Variation in Organisms.—The study of variation in organisms reproducing asexually, such as bacteria and viruses, has not yet led to any compact body of generalization at all comparable to that of classical genetics. An immense amount of work has been done on bacterial variation ever since Pasteur's demonstration that attenuated variants might be used to immunize animals against a more virulent strain of the corresponding bacterial type. Most of such work has been done by methods which provide no data as to the frequency with which mutants appear nor any evidence as to whether the variant finally obtained was a primary mutant from the parent strain or appeared only as a result of a progressive series of heritable changes. There is a general tendency in the literature to avoid expressing an opinion even as to whether the variations observed result essentially from discontinuous mutation with selective survival of variants particularly suitable to the abnormal experimental environment, or whether they are to be regarded as modifications produced by a direct somatic effect (Lamarckian) of the changed environment.—Burnet, Frank MacFarlane: *Virus as Organism*, Cambridge, Mass., Harvard University Press, 1945.

THE ABUSE OF ENDOCRINE THERAPY IN GYNECOLOGY

LIEUTENANT (JG) F. JACKSON STODDARD
(MC), U.S.N.R.

An analysis of a group of cases seen in the Department of Obstetrics and Gynecology of the University of Michigan Hospital has disclosed a need for greater clarification in the management of the gynecologic patient. The abuse of endocrine therapy prior to adequate diagnosis is illustrated in the cases reported here and summarized in the table.

REPORT OF CASES

CASE 1.—A married nulliparous woman aged 23 gave a history of normal menstrual periods until five months prior to admittance. She reported intermittent, bright red vaginal bleeding for one month previous to the institution of diethylstilbestrol therapy. She had passed no tissue but soiled one to two pads daily throughout a four month period of endocrine

Sample Cases in Which Endocrine Therapy Was Improperly Used

Incorrect Diagnosis	Hormone Preparation Used	Correct Diagnosis
1. Functional bleeding.....	Diethylstilbestrol for 4 months	Incomplete abortion
2. Menopausal bleeding....	Diethylstilbestrol for 6 months	Far advanced carcinoma of cervix
3. Sterility.....	Pregnant mare's serum	Chronic pelvic inflammatory disease
4. Primary amenorrhea...	Chorionic gonadotropin for 2 years	Congenital absence of uterus and vagina
5. Secondary amenorrhea.	Diethylstilbestrol for 3 months; pralone	Arrhenoblastoma of ovary
6. Menopausal symptoms.	Diethylstilbestrol for 1 year	Thyroiditis
7. Hypermenorrhea.....	Estrogens, progesterone, pregnant mare's serum, testosterone	Hypothyroidism
8. Senile vaginitis.....	Diethylstilbestrol for 9 months	Carcinoma of vulva

treatment. Pelvic examination had not been made and the patient was referred to us with the diagnosis "functional bleeding."

Admittance pelvic examination revealed nothing unusual. The Aschheim-Zondek test was negative. Dilatation and curettage revealed necrotic chorionic and decidua tissue. Had a careful pelvic examination been performed or a biologic test for pregnancy been made at the onset of her trouble, prior to the institution of therapy four months earlier, the true diagnosis might have been arrived at and appropriate treatment instituted.

CASE 2.—A woman aged 42, tertipara, tertigravida, had been treated with 1 mg. of diethylstilbestrol daily for six months for what she was told was "menopausal bleeding." No pelvic examination had been made.

Examination on admittance revealed a far advanced squamous cell carcinoma, grade 3, of the cervix.

CASE 3.—A woman aged 30, nullipara, primigravida, giving a history of an infected instrumental abortion five years earlier, had been treated for sterility with weekly injections of pregnant mare's serum for one year prior to admittance to the University of Michigan Hospital. Her menstrual periods had always been normal.

From the Department of Obstetrics and Gynecology of the University of Michigan Hospital, Ann Arbor.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

Pelvic examination revealed bilateral adnexal tenderness and thickening. Lipiodol uterosalpingography revealed bilateral tubal obstruction. Had the uterogram been performed one year earlier, the patient might have been spared considerable discomfort and expense. In this case tubal obstruction secondary to an old salpingitis was the most likely cause of her sterility.

CASE 4.—A woman aged 18, nullipara, nulligravida, received chorionic gonadotropin for two years in an attempt to bring on her menses. This had not occurred.

Examination on admittance, which was her first examination in years, revealed congenital absence of the uterus and vagina but normal development of secondary sex characteristics. An artificial vagina was constructed by Dr. Norman F. Miller. The patient was advised that while she would never bear children she could marry. Subsequent follow-up has shown her to be a well adjusted married young woman.

CASE 5.—A woman aged 18, nullipara, nulligravida, entered with the complaint of cessation of menses two months previously associated with deepening of the voice and generalized hirsutism. General physical examination, with the exception of the hirsutism, was negative. The masculinizing symptoms progressed, including enlargement of the clitoris. Laboratory studies, including basal metabolism tests, vaginal smears, endometrial biopsies and salt and water balance studies, all performed over a period of months, shed no light on the true diagnosis. Androgenic assay tests were not available at that time. The patient was placed on cyclic diethylstilbestrol-pranone therapy for three months without results.

Approximately one year after she was first seen she complained of severe constipation and a gradually enlarging abdomen. Pelvic examination at this time showed a grapefruit sized right ovarian neoplasm. An oophorectomy was performed and microscopic examination revealed a tumor of the arrhenoblastoma type. One month following removal of the tumor a normal menstrual period occurred, her first since the onset of symptoms. Periods have continued regularly over a period of two years. Masculinizing symptoms have decreased to some extent.

In this case, had frequent pelvic examinations been performed, no doubt the diagnosis would have been made earlier and both the patient and her physicians spared considerable anguish.

CASE 6.—A woman aged 48, primipara, primigravida, who had passed her menopause three years previously, entered complaining of increased nervousness, palpitation, weight loss and hot flushes. These symptoms had been present for fifteen months. During much of that time she had received 0.5 mg. of diethylstilbestrol daily for what she was told was "change of life."

Physical examination showed a mild tremor of the fingers, a warm moist skin, slight exophthalmos and a palpably enlarged thyroid gland. The basal metabolic rate was plus 45 per cent. Thyroidectomy resulted in pronounced improvement of symptoms.

While there is some evidence to show that estrogens may have a suppressive effect on thyrotoxicosis, it is doubtful that diethylstilbestrol was given with this intent. More likely the true diagnosis had been overlooked.

CASE 7.—A woman aged 24, nullipara, nulligravida, entered complaining of excessive menstrual flow. Her menses had always been heavy, but for the previous four years they had lasted ten to twelve days and she saturated four to twelve pads daily. During this time she had received estrogens, progesterone, testosterone and gonadotropins without lasting improvement. In addition she had received three blood transfusions, vitamin K, intramuscular liver extracts and iron preparations. The history revealed in addition that she was *droovy* much of the time, had a poor appetite and seldom perspired.

Admittance physical examination showed that she was thin and apathetic and that her skin and hair were dry. Her hemoglobin was 55 per cent. The basal metabolic rate was minus 30 per cent. Estrogen and gonadotropin assays were within

normal limits. The patient was placed on thyroid, the dosage being controlled by clinical response and basal metabolism tests. After three months her periods became normal and her general condition improved. At present she takes 2 grains (0.13 Gm.) of thyroid daily and has basal metabolism tests twice a year.

CASE 8.—A parous woman aged 76 was admitted with the complaint of pain in her groin, which had become progressively worse during the previous nine months. She had been using various ointments locally and had intramuscular injections of an estrogenic preparation twice weekly during that time, without relief. Morphine was finally resorted to when the pain became intractable. The patient had previously refused pelvic examinations.

On admittance pelvic examination revealed a large fungating mass which had replaced the vulva and invaded the vaginal canal. Bilateral enlarged inguinal nodes were present. Because of the advanced stage of the neoplasm a simple vulvectomy was performed as a palliative measure. This resulted in considerable relief of pain. Histologically the neoplasm proved to be a grade 2 squamous cell carcinoma of the vulva. If this patient had submitted to pelvic examination earlier, complete surgical extirpation might have been possible.

COMMENT

The great strides which have been made in understanding the internal secretions of the gonads has led to overzealousness on the part of some physicians, with the result that almost any abnormality of the female generative tract may be interpreted as being due to an endocrine imbalance. Unless carcinoma, inflammatory disease, complications of pregnancy and systemic diseases are carefully ruled out, grave errors in therapy may result.

Carefully taken histories and thorough physical examinations are essential. Diagnostic laboratory tests should include urinalysis, blood counts and careful microscopic examination of biopsy material. Biologic tests for pregnancy and metabolism tests may also be of value. What at first may appear to be a functional disturbance may, after careful investigation, be found to have a different cause.

The various laboratory procedures used to determine the status of the endocrine glands may be of value in selected cases but should not be relied on to the exclusion of the time tried diagnostic measures that have been enumerated.

No attempt has been made to discuss the proper use of endocrine preparations in the field of gynecology. There is a place for them, but their use should be restricted to those cases in which the diagnosis of an endocrine disturbance has been clearly established.

SUMMARY

1. A group of cases was encountered which showed how incomplete diagnostic studies may lead to improper treatment.
2. Endocrine preparations are frequently used unjustifiably because of the current focus on endocrine imbalance as a cause of symptoms referable to the female generative tract.
3. Resort to time tried diagnostic measures might have resulted in earlier disclosure of the true diagnosis in the 8 cases studied.
4. Sex hormone excretion studies may be helpful in selected cases.
5. Endocrine therapy has a definite but limited place in gynecologic practice.

CHRONIC HYPOCHLOREMIA SIMULATING PSYCHONEUROSIS

MAJOR WILLIAM SAPHIR

MEDICAL CORPS, ARMY OF THE UNITED STATES

Under conditions of sustained heat, as in the tropics, fluctuations of the level of the blood chlorides are likely to occur. Prolonged exposure to heat associated with physical activity will lead to salt depletion and diminution of blood chlorides.¹ If such deficiency is not made up and restoration of blood chlorides does not take place, symptoms of salt deficiency become manifest.

The symptoms of heat exhaustion due to salt deficiency are described as pronounced weakness, dizziness, stupor, pallor, profuse perspiration, diminution of urine, acceleration of pulse rate and respiration, lowering of blood pressure, and occasional cramping pains in the muscles of the abdomen and extremities (heat cramps).² The onset is usually sudden and not necessarily associated with exertion.

The diagnosis of heat exhaustion due to salt deficiency hardly presents difficulties as long as such a clinical picture is kept in mind. A determination of blood chlorides would seem unnecessary, as the rapid response to administration of salt makes the diagnosis obvious.

However, if salt depletion and loss of chlorides is less rapid and more protracted, the acute symptoms of salt deficiency may be less evident and may be modified to such an extent as to present diagnostic difficulties. The resulting clinical picture may be confusing and difficult to interpret.

It is my purpose in this paper to present briefly 10 cases of chronic hypochloremia that offered a striking resemblance to psychoneurosis. In none of the cases did the diagnosis become apparent until blood chloride determinations were done. In all cases there was prompt relief of symptoms on restoration of their blood chloride level to normal.

BLOOD CHLORIDE DETERMINATIONS

Blood chloride determinations were performed according to Army standard methods (Whitehorn).³ Numerous determinations revealed a normal range of from 400 to 500 mg. of sodium chloride per hundred cubic centimeters of whole blood, which is equivalent to 68.4 to 85.5 milliequivalents per liter.

REPORT OF CASES

CASE 1.—A private aged 24 was admitted on May 5, 1944 with the following note from his battalion surgeon: "I have observed Pvt. — for a number of weeks and cannot come to any definite conclusion. His complaints are vague—weakness, lassitude, general pains here and there. . . . He has never had elevation of temperature. I doubt if there is any psychoneurosis involved and suspect some amount of exaggeration and malingering. . . ."

The patient appeared well nourished, nervous and apprehensive. He had been overseas for twenty-two months, most of which time was spent in the tropics. He complained of general weakness and easy fatigability. He felt quite irritable and depressed without apparent cause. He had been taking an unspecified number of salt tablets irregularly.

Technician 5th Grade Ralph F. Hirschmann, Medical Department, performed the blood chloride determinations.

1. Miller, Michael; Silverman, M.; Jacob, J., and Powell, V. E.: Failure of the Sweat Mechanism in the Desert. J. A. M. A. 124:1152 (April 15) 1944.

2. Cecil, L. R.: A Textbook of Medicine, ed. 6, Philadelphia, W. B. Saunders Company, 1944.

3. Methods for Laboratory Technicians, United States War Department Technical Manual 8-227, Washington, D. C., Government Printing Office, Oct. 17, 1941.

Physical examination revealed a moderate tremor of the hands and exaggerated tendon reflexes. There were no other significant physical findings. The blood pressure was 120/70. Blood counts, malaria smears, urine analysis and chest x-ray examination were all normal. A blood chloride determination revealed a value of 363 mg. per hundred cubic centimeters.

The patient was given a high caloric diet with vitamin supplements and 60 grains (4 Gm.) of sodium chloride daily. A week later blood chlorides had risen to 411 mg. per hundred cubic centimeters. The patient felt fine and elated about the disappearance of the distressing symptoms. He was discharged to duty ten days after hospital admission.

CASE 2.—A private aged 29, admitted on May 1, 1944, had been in the tropics for the past eleven months and had been well able to participate in all the physical activities required until about one month prior to hospital admission. At that time he became aware of loss of strength and appetite. Epigastric distress without relation to meals, mild nausea and a sensation of fullness were present. The symptoms gradually increased in intensity so that hospitalization became necessary.

Physical examination revealed that the patient was fairly well developed and did not appear acutely ill. There was vague and mild epigastric tenderness without any other significant physical findings. A gastrointestinal x-ray study was entirely negative. Gastric analysis revealed a fasting value of 0 free and 8 total acidity, one hour after a test meal 42 free and 52 total acidity. Three stool specimens were free from occult blood, ova and parasites. Blood counts, urine analysis and malaria smears were all normal. A blood chloride determination revealed a value of 366 mg. per hundred cubic centimeters.

The patient was given a regular diet with vitamin supplements and 60 grains (4 Gm.) of sodium chloride daily. He improved rapidly. After five days the blood chlorides had risen to 400 mg. per hundred cubic centimeters. The symptoms subsided and the patient was discharged to duty.

CASE 3.—A corporal aged 20, admitted on May 9, 1944, had been overseas for only three weeks. While he had had some vague, intermittent dyspeptic symptoms for many months there had been considerable aggravation since he had been overseas. There were epigastric, postprandial distress, nausea and anorexia. There were increasingly severe nervousness, apprehension, depression and insomnia.

Physical examination revealed that the patient was well developed and that the blood pressure was 110/70. There were moderate tremor, exaggeration of tendon reflexes and mild diffuse epigastric tenderness. No other significant physical findings were present.

Urine analysis, blood counts, malaria smears and stool examinations for occult blood, ova and parasites were all normal. Gastric analysis revealed a fasting acidity of 28 free and 38 total, one hour after a test meal 36 free and 42 total acidity. A blood chloride determination revealed a value of 363 mg. per hundred cubic centimeters.

Sixty grains (4 Gm.) of sodium chloride daily together with rest, a full diet and vitamin supplements was followed by pronounced improvement, and the patient was discharged to duty eight days after admission.

CASE 4.—A corporal aged 27, admitted on May 9, 1944, for several weeks past had noticed increasingly severe epigastric distress, nausea and occasional vomiting. There was postprandial aggravation of symptoms. Simultaneously there were loss of pep and strength, frequent headaches, nervousness and irritability. There were spells of depression and moodiness.

Physical examination revealed mild tremor, hyperreflexia and moderate midepigastric tenderness. The blood pressure was 140/80. Urine analysis, blood counts, malaria smears and three stool specimens were negative throughout. Gastric analysis revealed a fasting value of 40 free and 50 total acidity, one hour after a test meal 73 free and 82 total acidity. The value for blood chlorides was 366 mg. per hundred cubic centimeters. The same regimen as in previous cases was instituted. One week later the blood chlorides had risen to 420 mg. per hundred cubic centimeters. The patient felt well and symptoms had subsided. He was returned to duty eleven days after admission.

CASE 5.—A private aged 19, admitted on May 22, 1944, had always felt well until he arrived overseas four weeks before.

For the past three weeks he had noticed upper abdominal cramping distress aggravated by work but not related to food intake. There was no vomiting, and the appetite remained good. The patient had not been taking salt tablets regularly and stated that he had been perspiring freely.

Physical examination disclosed that the patient was well nourished; he was apprehensive, with moderate tremor and hyperreflexia. The abdomen was soft and the viscera were not palpable. There was mild upper abdominal tenderness. The blood pressure was 125/70. Laboratory findings were negative in regard to blood counts, urine analysis, malaria smears and stool examinations. Gastric aspiration revealed a fasting value of 4 free and 8 total acidity, one hour after a test meal 20 free and 30 total acidity. The blood chlorides were 370 mg. per hundred cubic centimeters. Regular diet, multivitamins and 60 grains (4 Gm.) of sodium chloride daily were given. The patient improved rapidly. In one week the blood chlorides had risen to 410 mg. per hundred cubic centimeters and the patient was returned to duty free from symptoms sixteen days after hospital admission.

CASE 6.—A technical sergeant aged 30, admitted on May 27, 1944 with a tentative diagnosis of peptic ulcer, had an overseas stay of three months. For the past four weeks there was epigastric burning distress without relation to food intake. There were frequent vomiting, anorexia and nausea associated with headaches and dizziness. There was weakness and some prostration.

Physical examination disclosed that the patient was apprehensive and in a fair state of nutrition. There were moderate tremor, hyperreflexia and dermatographism. The abdomen was flat and soft. The viscera were not palpable. There was mild diffuse epigastric tenderness. Blood counts, urine and stool examinations and malaria smears were negative. Gastric analysis showed a fasting value of 50 free and 58 total acidity, one hour after a test meal 16 free and 26 total acidity. The value for blood chlorides was 370 mg. per hundred cubic centimeters. Rapid improvement followed proper salt medication. The blood chlorides rose to 425 mg. per hundred cubic centimeters within a week and the patient was discharged to duty free from symptoms and feeling well.

CASE 7.—A technician aged 32, admitted on June 1, 1944, had been overseas for one and one-half years, most of which time was spent in the tropics. For the past six months he had become increasingly nervous. He felt unable to concentrate on any task and consequently could not carry out orders satisfactorily. This in turn made him depressed and blue. He began to worry and exhibited a behavior suggestive of intense anxiety, according to the accompanying statement of the referring battalion surgeon.

The patient complained of headaches and nervousness and appeared in a state of tension and depression. There were no significant physical findings. Laboratory tests including blood counts, sedimentation rate, urine analysis, stool examinations and malaria smears were not contributory. A chest x-ray was negative. The blood chlorides were 365 mg. per hundred cubic centimeters.

Sodium chloride 2.5 Gm. three times a day was given. The patient improved gradually and progressively. After nine days the blood chlorides had risen to 415 mg. per hundred cubic centimeters. The patient was returned to duty fourteen days after admission, feeling fine and free from symptoms.

CASE 8.—A private aged 24, admitted on Aug. 3, 1944, had spent most of his twenty-three months overseas service in tropical theaters of operation. For the past few weeks he had suffered from increasingly severe headaches, nausea, anorexia and weakness. He felt depressed and irritable. A sudden aggravation of the condition occurred one day prior to hospital admission when the patient was working hard with little food and much perspiration. He felt extremely weak and dizzy and had to stop working. He had taken salt tablets rarely and irregularly.

Examination revealed moderate dehydration, some tremor and hyperreflexia. The blood pressure was 120/82. No other significant findings were obtained. Urine, stools, malaria smears and blood counts were negative. Fasting gastric aspiration disclosed a value of 0 free and 9 total acidity, one hour after a

test meal 32 free and 42 total acidity. The blood chlorides were 363 mg. per hundred cubic centimeters.

Salt tablets, 20 grains (1.3 Gm.) three times a day, were administered, together with vitamin supplements and a regular diet. Rapid recovery took place. The blood chlorides rose to 403 mg. per hundred cubic centimeters within a few days and the patient was returned to duty six days after admission, feeling well and free from symptoms.

CASE 9.—A private aged 23, admitted on Sept. 8, 1944, had been overseas for five months and felt well until six weeks before, when he gradually developed headaches, insomnia and dizziness. He felt progressively worse, had "blue spells" and "hot flushes" and became quite irritable and depressed. He vomited occasionally and felt increasingly nervous. At times he became quite fearful as if disaster were impending. He was unable to remain on duty status and was hospitalized.

Physical examination failed to disclose significant findings. Blood counts, sedimentation rate, Kahn test, urine analysis and malaria smears were all normal. Fasting gastric acidity was 0 free and 10 total acidity, one hour after a test meal 21 free and 30 total acidity. The blood chlorides were 370 mg. per hundred cubic centimeters.

Salt tablets 20 grains (1.3 Gm.) three times a day, vitamins, regular diet and rest were given. The patient improved rapidly. Headaches and psychoneurotic manifestations subsided and the patient was returned to duty eighteen days after admission with a blood chloride level of 420 mg. per hundred cubic centimeters.

CASE 10.—A private aged 25, admitted on Nov. 5, 1944, had been overseas for thirty-one months, most of which time was spent in tropical theaters of operation. For the past several months he had felt increasingly nervous and irritable. He had spells of palpitation and dyspnea associated with dizziness and extreme weakness.

Examination disclosed that the patient was fearful and apprehensive, with considerable tremor, hyperreflexia and hyperhidrosis. The heart action was rapid and forceful without enlargement or murmurs. The blood pressure was 160/102. Urine analysis, blood counts, malaria smear and a chest x-ray were all normal. The fasting gastric content revealed 0 free and 9 total acidity, one hour after a test meal 35 free and 44 total acidity. The value for blood chlorides was 380 mg. per hundred cubic centimeters.

Rest, regular diet, multivitamins and sodium chloride 60 grains (4 Gm.) daily were administered. Considerable improvement of the distressing symptoms took place and the blood chlorides rose to 440 mg. per hundred cubic centimeters. However, the blood pressure remained high and the patient was therefore evacuated.

COMMENT

An analysis of these cases reveals that chronic hypochloremia can give rise to a variety of symptoms. These symptoms may be divided into two groups, one related to the intestinal tract, the other to the nervous system. Intestinal symptoms were vague epigastric distress without definite relation to food intake, abdominal cramps, anorexia, frequent nausea and occasional vomiting. Symptoms related to the nervous system were headaches, dizziness, tremor, hyperreflexia, hyperhidrosis, nervousness, apprehension, restlessness, insomnia with loss of pep and strength, depression, personality changes and even frank anxiety.

Consequently all the patients were originally assumed to be suffering from a psychoneurosis. For even when the alimentary symptoms predominated, the absence of significant organic and laboratory findings led us to suspect the presence of a conversion psychoneurosis with psychosomatic manifestations of the intestinal tract.

It was only through determination of the blood chlorides that the true nature of the disorder became manifest. Rapid improvement of all "psychoneurotic" symptoms took place on restoration of the blood chloride level to normal.

Just what factors were responsible for the salt deficiency in these cases is not clear. It may be reasoned

that the patients had taken enough salt to prevent a sudden depletion of chloride stores with its typical picture of acute heat exhaustion. But they had not taken enough to prevent a gradually increasing chloride deficit. The history obtained from these patients appears to substantiate this assumption.

A noteworthy finding was the normal or even increased value (cases 6, 4) of gastric acidity. This may indicate that, in the face of impending salt deprivation, depletion of such sodium chloride stores as the subcutaneous tissue may take place long before the important function of gastric hydrochloric acid synthesis is interfered with. Sodium chloride balance studies might have shed some light on the mechanism involved in the breakdown of our patient's salt metabolism, but such studies were beyond the scope of this paper.

The length of tropical overseas service apparently had no bearing on the condition. One patient (3) was overseas only three weeks, another (patient 10) thirty-one months.

A recent report of the chief surgeon of the U. S. Army Forces in the Middle East⁴ deals in part with the effect of prolonged exposure to heat. The clinical entity described by him as "heat syndrome" bears some resemblance to the cases described herein. It is stressed that this heat syndrome has no relation whatever to heat stroke and heat prostration, which have been studied so thoroughly.

Finally, attention is called to the possibility that chronic hypochloremia may remain unrecognized if not specifically searched for. There seems little doubt that rest, a normal diet, diminution of physical activity and hidrosis will restore a previously low blood chloride level to normal without addition of salt tablets. Improvement of psychoneurotic symptoms may then be erroneously attributed to psychotherapeutic measures, and the true nature of the condition may remain obscure. The value of blood chloride determinations in such cases appears obvious.

SUMMARY AND CONCLUSIONS

- 1. Ten cases of chronic hypochloremia were observed.
- 2. The clinical symptomatology is vague and resembles a psychoneurosis with various psychosomatic manifestations related to the vasomotor system and the alimentary canal.
- 3. Prompt recovery took place on restoration of the blood chloride level to normal.
- 4. The importance of blood chloride determinations in differentiating psychoneurosis from chronic hypochloremia is evident.

Virus Infection in Childhood.—In childhood the effectiveness of response to infection increases, and there is hardly an exception to the rule that any infectious disease met for the first time will show a lower average severity in well nourished children of ages 6-12 than in any other age group. With some diseases the difference is striking: there is practically no mortality, in unprotected European children from yellow fever; clinical psittacosis is virtually unknown in this age group; and, in the 1918-19 pandemic of influenza, deaths in childhood were negligible in comparison with the high mortality in young adults. The relatively benign character of infection in the young is also evident in some other species, notably in regard to several protozoal diseases of cattle.—Burnet, Frank MacFarlane: *Virus as Organism*. Cambridge, Mass., Harvard University Press, 1945.

WOMEN IN MEDICINE

FLORENCE DE L. LOWTHER, PH.D.

AND

HELEN R. DOWNES, PH.D.

Associate Professor of Zoology and Associate Professor of Chemistry,
Respectively, Barnard College
NEW YORK

The question of the effectiveness of American women as physicians has reached the point where its clarification has become imperative. Dr. H. G. Weiskotten¹ shows that over the past twenty years American medical colleges have limited their registration of women to approximately 5 per cent of the total enrolment. Since

it is reported that English medical schools are currently admitting women to the extent of 20 per cent, the arguments leveled in this country against their admission seem to require reevaluation.

The chief of these arguments relies for its force on the statement that women marry and leave the profession, making it sheer waste to spend the large sums involved on their training. This contention is often bolstered with figures of doubtful authenticity culled from the speaker's immediate experience, some of them at least being related to those of the doctor who spoke of a class in which "50 per cent of the women dropped out" without explaining that only 2 women had entered.

The present study presents the results of an investigation undertaken to discover what use the women grad-

uates of seven representative Eastern medical colleges have made of their training. It covers the careers of the women who, in the eighteen or twenty years before 1940, graduated from the medical schools of Columbia, Cornell, Johns Hopkins, New York and Yale universities, the University of Pennsylvania and the Woman's Medical College of Pennsylvania.

research, teaching in medical colleges and institutional medicine. The information in the last column of the table was obtained from the questionnaires sent out in 1942 and shows that an additional 22 women are engaged in such part time work, often voluntary, as clinics, Red Cross blood banks, research projects and school and public health activities. Those physicians who have died and about whose activities no information is available have been omitted entirely from table 1 (29 cases). Those, however, who are known to have practiced until the time of their death (7 cases) as well as those who have retired after fifteen or twenty years of practice (4 cases) have been included in the active list.

Since these figures were obtained after the beginning of 1942 it might be inferred that the war is responsible for the high percentage of active women physicians. It may be pertinent therefore to emphasize the fact that the information in the directory would have been gathered too early to reflect the response of women to the war emergency. Replies to questionnaires have

Dean Martha Tracy² had already shown that the questionnaire method elicits only a limited response, 36 per cent in her case, after two trials. In the hope of making as complete a study as possible, the record of each graduate in the present group has been investigated, making use of the American Medical Directory for 1942 (the latest available) and of records in alumni and medical college administrative offices. If a graduate's name did not appear in the directory or was listed as "not in practice" a questionnaire was sent to learn whether she was listed under a married name or was using her medical training in any way. The information brought together in the accompanying tables is therefore chiefly as of 1942-1943, with occasional corrections from questionnaire replies. The total number of women whose records have been studied is 1,240, which according to Dr. Weiskotten is equal to about a third of the women graduated in the past eighteen years and to one sixth of the total number of women physicians registered in the entire United States in 1942.

The investigation shows that of these 1,240 women graduates 1,115 (90 per cent) were in 1942-1943 in full time medical work (table 1). For our purposes we have defined "full time medical work" to include, besides medical practice, public health work, medical

shown that only 7 now included in the full time list, and 3 on the part time, returned to practice after the outbreak of the war. It has been impossible to include in the present report the responses to questionnaires sent to graduates of the Woman's Medical College. It should therefore be held in mind that their recorded percentage of activity is probably somewhat too low.

2. Tracy, Martha: *Bull. Am. Med. Coll.* 3: 327, 1928.

Since the major argument against the admission of women to medicine is predicated on the assumption that marriage automatically terminates their professional activities, the number of married women physicians has been investigated. It is a satisfaction to be able to report that 82 per cent of those who have married have remained in full time medical work (table 2). Since the overall activity is 90 per cent, this represents a comparatively small drop attributable to marriage. Furthermore, as it is the custom for many women to continue to use their maiden names in practice, and alumni records are not always complete in these cases, the number of married graduates has almost certainly been underestimated. As in the case of all married professional women, it is understood that short maternity leaves have been taken in some cases.

It is of course true that if women as a group are to justify their claim to a place in the medical profession, they must do more than practice. A just criterion for the measurement of the extent to which any group has made significant or distinguished contribution to the advancement of a science is not easy to find. One indication of such contribution on the part of this group is to be found in the number of specialists, another in the number who hold professional appointments in medical colleges.

The figures in table 3 show that 24 per cent of the total number of women engaged in full time medical work have taken enough advanced training to qualify as exclusive specialists, while a further 8 per cent combine partial specialization with general practice. The types of specialization chosen by the 273 women physicians who devote themselves to a single field are indicated in table 4. As might be expected, pediatrics leads with 24 per cent of the total, but psychiatry claims 15 per cent and internal medicine 12 per cent. It is perhaps surprising that obstetrics and gynecology together fall below these, with only 11 per cent representation. It would be interesting to know how much this distribution has been dictated by preference and how much by the relative ease of obtaining hospital appointments. In view of the difficulty in getting surgical internships for women, it is gratifying to find that at least 4 women in this group have persevered in this field. Of these one is now a surgeon in the British army, with the rank of major.

A further measure of accomplishment is to be found in the number of appointments from this group to professorial rank in approved medical colleges. The figures in table 5 all date back to 1942 and mean that in the face of a very considerable prejudice and competition 31 of the 50 women holding such appointments had made their way to positions on the faculty of coeducational medical colleges. It may be objected that this number is small, but in view of the obstacles to their advancement it seems large enough to carry some weight.

The evidence here presented indicates that women physicians as a group have amply justified their training and that marriage has had a negligible effect on their professional activities. They have in a high percentage of cases rendered active service to medicine, and a reasonable proportion of them have taken advanced training and entered a wide variety of special fields. On the basis of this record it would seem that American medical colleges might well consider accepting a higher percentage of women in the future.

Clinical Notes, Suggestions and New Instruments

A MODIFICATION OF HARRISON'S TEST FOR BILIRUBIN IN THE URINE ESPECIALLY SUITED FOR MASS AND SERIAL USAGE

VIOLET HAWKINSON, B.S.; C. J. WATSON, M.D.
MINNEAPOLIS
AND

COLONEL ROY H. TURNER
MEDICAL CORPS, ARMY OF THE UNITED STATES

The increased incidence of infectious jaundice during the war has focused attention on the need for simple tests which will aid in the early detection of the disease and in following its course. The observation of Neefe and Stokes¹ that bilirubin may appear in the urine in cases of experimentally induced hepatitis before any elevation of the total serum bilirubin is observed is in itself indicative of the need of a simple sensitive and reliable procedure by means of which large numbers of urine samples can be examined rapidly for the presence of bilirubin. It is, of course, well known that the urine often becomes dark in cases of infectious hepatitis one or more days before the appearance of jaundice, and in some instances of hepatitis without jaundice the presence of dark urine for a short period of time early in the course of the disease may be the only evidence of jaundice in the broad sense of the term. That this is not a new observation is amply attested by the following passage from George Budd's treatise on "Diseases of the Liver" published in 1846:²

"The coloring matter of bile may be detected in this way in the urine even before the skin becomes yellow, and in some cases the redness with which it passes off in the urine seems to prevent the occurrence of jaundice—the skin retaining its natural color while the tint of the urine attests to the presence of bile."

Harrison³ employed 10 per cent barium chloride in carrying out the test for bilirubin which has come to be widely known as the Harrison test. In this procedure 10 cc. of urine and 10 cc. of the barium chloride solution are mixed, after which the voluminous precipitate of insoluble barium salts is filtered off on a small filter paper. Fouchet's reagent is then dropped on this precipitate and the characteristic green color of biliverdin is noted if bilirubin was present in the initial urine sample. According to Foord and Baisinger⁴ this method was as sensitive as any of a number of others with which it was compared and more sensitive and satisfactory than many. It was believed that this procedure, although relatively simple, might be simplified further to a point where it would be much more easily applied to mass usage, as in the armed services or in industries where it is desired to screen large numbers of personnel with respect to latent hepatic injury. With this objective in mind, the following technique has been devised and has been shown to be equivalent to the original Harrison method.

DESCRIPTION OF METHOD

A. Preparation of Barium Impregnated Paper Strips or Cotton Swabs.—Pieces of extra thick and retentive filter paper (Schleicher and Schuell number 470) are allowed to remain briefly in a saturated aqueous solution of barium chloride. They are then dried in the air or, preferably, in a drying oven, after which they are cut into strips 4 inches long by $\frac{1}{2}$ inch wide. A single strip is used for one test, as described in the following. If a suitable type of thick filter paper is not available, cotton swabs may be used, although the resulting test is not quite as sensitive and clearcut as with the filter strips.

Aided by a grant from the Josiah Macy Jr. Foundation, New York. From the Department of Medicine, University of Minnesota Hospital, Minneapolis.

1. Neefe, J. R.; Stokes, Joseph, Jr.; Reinhold, John G., and Lukens, F. D. W.: Hepatitis Due to the Injection of Homologous Blood Products in Human Volunteers, *J. Clin. Investigation* 22:1836, 1944.

2. Budd, G.: *Diseases of the Liver*, Philadelphia, Lea & Blanchard, 1846, p. 368.

3. Harrison, G. A.: *Chemical Methods in Clinical Medicine*, London, J. & A. Churchill, 1937.

4. Foord, A. G., and Baisinger, C. F.: Comparison of Tests for Bilirubin in Urine, *Am. J. Clin. Path.* 10:218, 1949.

The swabs are prepared on ordinary applicator sticks, the cotton having dimensions of about $1\frac{1}{2}$ inches by $\frac{1}{2}$ inch. These are dipped in the saturated aqueous solution of barium chloride and, after drying, are ready for use.

B. Procedure.—One end of a barium chloride impregnated thick filter strip is placed in the urine sample to be tested, the strip being in an approximately vertical position, at least one half extending above the surface of the sample. After standing in the urine for from thirty seconds up to two minutes the strip is withdrawn and placed on a piece of dry paper such as a paper towel or any other absorbent paper. Inspection of the filter strip will usually reveal somewhat more color in that area which corresponded to the surface of the urine. Two to three drops of Fouchet's reagent⁵ are then dropped directly on this area. A positive test is denoted by the appearance of a green color, varying in intensity with the amount of bilirubin present. With smaller amounts the color is often detected as a faint green line running across the strip.

When the cotton swab is used it is momentarily immersed in the urine to be tested. Excess urine is expressed from the swab by rolling it against the side of the container. Two to three drops of Fouchet's reagent are then dropped in the middle of the swab, a positive test being denoted as just described. In our experience the weaker reactions are less easy to interpret in that the reaction is over a larger area and hence more diffuse and not as clearcut as the line reaction observed with the filter strip method. Nevertheless the swab method has considerable usefulness when the proper type of filter paper is not available. To date the only paper that we have found suitable has been the S & S number 470, but it is quite possible that other varieties which we have not tried would be just as satisfactory.

In a number of instances a series of dilutions of bilirubin containing urines have been made to a point where the ordinary Harrison test was either questionable or absent. In each instance the results obtained with the present method were entirely comparable. Thus it is believed that the present filter strip method is at least equivalent to the original Harrison procedure.

It may be noted that barium has a peculiar virtue, possibly of catalytic nature, in this reaction. The test is not as sensitive when calcium chloride is used, although calcium salts appear to adsorb bilirubin from the urine just as efficiently as barium.

THE TREATMENT OF CARDIOVASCULAR SYPHILIS WITH PENICILLIN

RALPH E. DOLKART, M.D.

AND

GEORGE N. SCHWENGLIN, M.D.
CHICAGO

Several reports¹ have appeared dealing with the use of the penicillin salts in the treatment of early syphilis, benign late, early and late congenital syphilis and neurosyphilis since the original report of Mahoney, Arnold and Harris² in June 1943. Thus far there have been no available reports concerning the use of penicillin in cardiovascular syphilis.

Recently we have had occasion to study the effect of penicillin therapy on 2 patients with syphilitic aortitis and were forced to discontinue therapy in both because of the untoward effects

5. Fouchet's reagent is composed of 25 per cent trichloroacetic acid containing 0.9 per cent ferric chloride.

noted. The present report seems in order because of the widespread interest in and the increasing usage of penicillin in the therapy of syphilis.

REPORT OF CASES

CASE 1.—R. C., a white man aged 56, came under our observation in December 1941, at which time he was admitted to the hospital because of cough and dyspnea associated with the onset of a severe upper respiratory infection. In 1903, at the age of 18, the patient had acute rheumatic fever. At this time he was told that he had a heart murmur. In 1908, at the age of 23, he had a penile sore and gonorrhea. He received syphilotherapy, arm and hip injections, at irregular intervals from 1908 to 1935. No treatment had been given since 1935, at which time he was told that his blood test was negative.

Physical examination on admission showed sticky rales throughout both lung fields; the blood pressure was 150 systolic and 90 diastolic. A 2 meter roentgenogram of the chest showed a transverse cardiac diameter of 17.5 cm., the heart occupying 52 per cent of the transverse diameter of the thorax. There was a grade 3, high pitched, blowing systolic murmur at the apex, a soft apical diastolic murmur and a harsh systolic murmur at the base of the heart. A Kahn quantitative blood test of 4 units was obtained, and the Hinton blood test was positive. The cerebrospinal fluid findings were normal, including a negative Kahn and Wassermann test. The patient was discharged symptom free on the fourteenth hospital day with a diagnosis of upper respiratory infection, acute bronchitis, rheumatic heart disease, mitral stenosis and insufficiency, aortic stenosis and late latent syphilis.

Between March 1942 and November 1942 the patient received thirty-eight weekly injections of 1.0 cc. of bismuth subsalicylate in oil intramuscularly. During this time he felt fairly well and had no complaints except exertional dyspnea. A Kahn blood test taken immediately after the bismuth therapy was negative. Periodic physical examinations during this interval demonstrated no essential changes in his findings except that an aortic diastolic murmur became evident.

On March 24, 1943 the patient was rehospitalized because of sharp, sticking pains in the left precordium associated with dyspnea. Physical findings were unchanged from those previously described. There was a definite aortic diastolic murmur present. The Kahn blood test was reported as doubtful positive. Two electrocardiograms were recorded during the course of this eight day hospital period, and no changes were noted from the previous tracings taken in December 1941, at which time there was a sinus rhythm, left axis deviation, inverted T₁, ₂, ₃, low T₄, M-shaped QRS₂, ₃ and depressed ST segments in leads 1 and 2.

In July 1943 the patient reentered the hospital for a period of six days because of an episode of vomiting, associated with burning precordial pain which radiated down both arms. Physical examination showed the blood pressure to be 124 systolic and 64 diastolic. A definite capillary pulsation was observed. The heart sounds were the same as previously recorded, and a roentgenogram of the chest showed a slight increase in the transverse diameter of the heart to 18.5 cm. The electrocardiogram was unchanged. Following this period the patient began to complain of precordial pain on effort. From July 1943 until September 1943 he received twelve weekly injections of 1.0 cc. of bismuth subsalicylate in oil.

In April 1944 the patient began to have increasing dyspnea. It was observed that his basal weight was increasing and his vital capacity on actual measurement had been slowly decreasing over the past year, going from 3,525 cu. cm. to 1,885 cu. cm. On April 22, 1944 he was hospitalized for treatment of congestive heart failure with pulmonary edema, ascites, serosal edema and edema of the extremities. On May 11, 1944 he was dismissed after digitalization and the use of diuretics. He was edema free at that time.

He was well throughout the summer of 1944. At rare intervals precordial pain ensued following strenuous effort. Several things should be noted during this interval. The Kahn quantitative blood test remained consistently at the level of 4 units. There seemed to be an increasing prominence of the ascending limb of the aorta on repeated fluoro-copy of the chest. He had received no anti-syphilitic therapy since September 1943.

It was at this juncture that reports began to appear on penicillin as a therapeutic agent for syphilis. It was our feeling that this man had an active syphilitic aortitis and that his life expectancy, in view of his recent congestive heart failure, was definitely limited. It was felt that arsenicals were contraindicated because of the suggestive evidence of coronary artery involvement as evidenced by effort angina. On Sept. 21, 1944 he was hospitalized and an attempt was made to treat the syphilitic aortitis with penicillin. A 2 meter roentgenogram of the chest and fluoroscopy showed no change in the heart size or lung fields since the last preceding examination on April 25, 1944. The blood pressure was 110-120 systolic and 60-80 diastolic in both arms. There were harsh apical and basal systolic and diastolic murmurs over the precordium. On September 23 he was given 10,000 units of sodium penicillin in distilled water intramuscularly. No untoward effects occurred, and on September 24 he received the same dosage without reaction. On the morning of September 25, 20,000 units of penicillin was administered intramuscularly. During the day the patient noted four episodes of anginal pain, each relieved by erythrol tetranitrate. These were similar to those previously experienced by the patient but occurred at bed rest in contradistinction to previous anginal pain occurring on effort. A second dose of 20,000 units of penicillin was given in the afternoon of the same day. On September 26 the patient received 60,000 units intramuscularly in three doses. He developed seven episodes of anginal pain and a sense of heart consciousness. On the following morning numerous extrasystoles were heard and confirmed electrocardiographically as being premature ventricular extrasystoles. Further penicillin therapy was discontinued. The extrasystoles were not in evidence when electrocardiograms and examination were performed two days and three, six and twelve weeks later. A quantitative Kahn blood test on November 20 was reported as 3 units.

Case 2.—T. G., a white man aged 56, admitted to the hospital on April 27, 1945, had an acute infection of the upper respiratory tract five days prior to admission, associated with nasal discharge and productive cough, which became progressively more severe. On the day prior to admission he began to have soreness of the throat, swelling of the neck, dysphagia and a cough productive of thick white mucus. The inventory by systems was negative except for 10 pounds recent weight loss and occasional joint pains. His past history included scarlet fever in 1911, typhoid in 1913, right herniorrhaphy in 1936 and excessive alcohol intake for twenty years. He stated that he had a penile sore in 1915 but stated that he did not have any knowledge that the lesion was syphilitic or that he had received any specific therapy.

On physical examination the temperature was 100.2 F. Both pupils were fixed to light. The tongue was swollen, red and tender. The posterior pharynx was slightly reddened and the anterior cervical glands were enlarged and tender. The heart was enlarged to the left. There was a systolic murmur audible at the apex and base and a diastolic murmur present at the base. The blood pressure was 140 systolic and 50-60 diastolic. The lung fields were clear, the liver palpable 5.0 cm. below the right costal margin in the midclavicular line. The remainder of the abdominal examination was negative. The patellar and achilles reflexes were absent. The clinical diagnosis was acute lingual tonsillitis, syphilitic aortitis and tabes dorsalis. A roentgenogram of the chest showed normal lung fields and a heart of aortic configuration with some enlargement. An electrocardiogram showed sinus rhythm, inverted T waves in all limb leads and left axis deviation. Laboratory examination on admission revealed hemoglobin 12.2 Gm., red blood cells 3.68 million, white blood cells 27,650, differential 83 per cent polymorphonuclears, 7 lymphocytes, 2 monocytes and 8 basophils. The sedimentation rate was 26 mm. in one hour. The urine was normal. A Kahn blood test was negative. The cerebrospinal fluid obtained on May 3 showed a strongly positive Wassermann reaction, 4 lymphocytes, 35 mg. total protein per hundred cubic centimeters and a colloidal gold curve of 0012200000. A throat culture was taken but was not satisfactory.

The patient was begun on sodium penicillin shortly after admission, receiving 20,000 units every two hours intramuscularly. His clinical response was satisfactory, the temperature and white blood cell count returning to normal on the third

hospital day, with rapid subsidence of the edema and soreness of the throat. He received a total of 700,000 units of penicillin from April 27 through April 30, 1945.

On April 30 he began to complain of intermittent precordial pain during the day, which by evening was moderately intense, and the penicillin therapy was discontinued. The precordial pain had ceased by the following morning. The infectious process in the throat having subsided uneventfully, the patient was dismissed on the seventh hospital day.

The patient's medical record, obtained from his previous physician, showed that he was first seen in 1936, at which time he had fixed pupils, absent patellar and achilles reflexes, a blood pressure of 145/60 and a systolic and diastolic murmur at the apex and base. The blood Wassermann and Kahn reactions were strongly positive. A diagnosis of central nervous system syphilis and syphilitic aortitis was made at this time. He received intermittent treatment consisting of bismuth, potassium iodide and neoarsphenamine for a period of three years until April 1939, when he failed to return. It was noted several times in 1938 and 1939 that the patient complained of precordial pain radiating down both arms, occurring on effort, which was relieved by rest. This was during the period when he was being given neoarsphenamine. He did not experience any recent precordial distress until that described during the penicillin therapy.

COMMENT

Wilson³ recorded 5 cases of late syphilis of the aorta in which conspicuous changes in the electrocardiogram developed after the administration of arsphenamine and related compounds. Tung and Mu,⁴ in an electrocardiographic study of 22 patients suffering from syphilitic aortitis with aortic insufficiency, found that significant changes in the ventricular complex of the electrocardiogram occurred in 2 cases and minor alterations in 5 cases within a few hours after the injection of neoarsphenamine.

Wilson advanced two possible explanations of the electrocardiographic changes observed after treatment. The first assumed that soon after intravenous therapy there occurred a reaction in the syphilitic aortic lesions at the mouths of the coronary arteries, or a replacement of the active lesion by scar tissue. The second explanation, which was preferred by Wilson, assumed that the effect of the arsphenamine therapy on the myocardial syphilomas may affect the integrity of the heart by interfering with the circulation locally. Tung and Mu thought that, since syphilis of the myocardium is rare and since the changes observed by them were similar to those observed in other cases of coronary artery disease, these changes were caused by a reaction in the syphilitic aortic lesions, with resultant encroachment on the coronary artery ostia. They thought that the fact that the electrocardiographic changes occurred almost immediately after treatment precluded the possibility of replacement by scar tissue as the cause in their cases.

It has been shown that there is a rapid involution of syphilitic lesions that may be observed under penicillin therapy, both of the early lesions and of the cutaneous gumma variety.⁵ While⁶ recently commented that he objected to the suggested use of penicillin in cardiovascular syphilis because of the likelihood of the type of reaction herein described taking place. He stated that he always felt that when cardiovascular syphilis reached a clinical horizon it should never be treated by intensive methods, for it is in such cases that one not infrequently sees a therapeutic paradox. In these instances we were forced to discontinue penicillin therapy in patients with cardiovascular syphilis because of the untoward effects. This is a preliminary report; other patients are now under investigation.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

The following additional articles have been accepted as conforming to the rules of the Council on Pharmacy and Chemistry of the American Medical Association for admission to New and Nonofficial Remedies. A copy of the rules on which the Council bases its action will be sent on application.

AUSTIN SMITH, M.D., Secretary.

INTOCOSTRIN.—A curare preparation containing therapeutically desirable constituents of curare.

Actions and Uses.—Intocostein has been shown by physiologic tests to have a substantially pure curare action; that is, it paralyzes the skeletal muscles. This paralysis results from an interruption of the nerve impulse at the myoneural junction. The diaphragm and intercostal muscles are usually the last to be affected. The action of the drug is brief because of rapid excretion and destruction. If respiration is embarrassed or arrested, neostigmine, a physiologic antidote, will assist in counteracting the curare effect, but properly instituted artificial respiration may be necessary to maintain respiration until the curare effect has diminished. The curare activity in intoxicostein is due almost wholly to the presence of an alkaloid, d-tubocurarine, which accounts for about half the total solids in intoxicostein. This alkaloid has been isolated as a pure crystalline salt. Intocostein may be used to soften the severity of convulsions and to prevent fractures in shock therapy of mental diseases; to produce muscular relaxation during the reduction of fractures or dislocations, or during certain manipulative diagnostic procedures; to produce a more or less transient reduction of hypertonia, tremor, incoordination, athetosis and dysarthria in certain neurologic conditions and, with certain precautions, to aid in the diagnosis of myasthenia gravis.

Intocostein can be used by those experienced in such use as an adjuvant to anesthesia. *The drug is not, however, without its dangers.* Overdosage produces paralysis of the respiratory muscles. Experimental work on dogs indicates the possibility of added toxic effects following the use of large doses of atropine with curare. Clinically, however, no difficulty has been encountered with therapeutic doses of belladonna alkaloids, and it is claimed that such premedication is desirable. The value of intoxicostein in anesthesia is the development of adequate muscular relaxation. It is claimed that the amount of anesthetic and depth of anesthesia may be decreased.

Dosage.—In softening the convulsions of shock therapy or to produce relaxation in manipulative procedures: 0.5 unit per pound of body weight (but the initial dose for adults should be 20 units less than this total), administered intravenously at a uniform rate during one to one and one-half minutes. Larger doses may be necessary, but if the estimated dose fails to produce paralysis another full paralyzing dose should not be given for twenty-four hours. Preparations should always be made to cope with respiratory failure. Neostigmine, 2 cc. of 1:2,000, should be at hand for intravenous injection if required, and an airflow should be available on the tray to assist in artificial respiration in the event of obstructed breathing. In spastic and athetoid states in children: 0.5 to 1.5 units per pound of body weight administered intramuscularly at four day intervals. As a diagnostic agent in myasthenia gravis: one fifteenth to one fifth of the average adult dose, intravenously followed always in two or three minutes by the intravenous injection of 1.5 mg. of neostigmine methylsulfate with 0.65 mg. of atropine sulfate.

In order to obtain muscular relaxation during light (second plane) anesthesia with cyclopropane, nitrous oxide or barbiturates, 40 to 60 units of intoxicostein may be administered when the skin incision is made: 20 to 30 units may be added in three to five minutes, if needed. If the operation has lasted more than forty-five minutes, an additional dose of 30 to 40 units may be cautiously administered if such additional dosage seems indicated. In an alternative method as much as 100 units has been administered in a single intravenous injection at the beginning of or during anesthesia, but no additional quantities should be given following this large dose until some time has elapsed and then extreme caution exercised. The drug apparently may be used with any type of anesthetic agent, *although with ether only about one third of the dose otherwise employed should be used.* It must be remembered, however, that the use of intoxicostein as an adjuvant to surgical anesthesia is still in a stage which requires continued careful study.

Curare has been extensively used with sodium pentothal anesthesia, usually by separate injection. If a barbiturate solution (alkaline) is mixed with intoxicostein solution (acid) a precipitate is formed, which is redissolved when a sufficient amount of the barbiturate with its buffer has been added. The precipitate is the free barbituric acid derivative. If an intoxicostein solution is alkalinized with sodium carbonate, no loss in potency occurs during a twenty-four hour period and no precipitate forms when the alkalinized solution is mixed in any quantity with a barbiturate solution. Such mixtures have not been used clinically; the present method is to inject the solution separately and alternately through a Y-tube using the same needle. When by this method intoxicostein follows the barbiturate, a slight fine precipitate forms at the surface of contact of the two solutions. It has been the custom to allow such a precipitate to be injected slowly, as it presumably redissolves on mixing with the plasma.

Preparation.

Intocostein prepared from *Chondodendron tomentosum* extract is made by first extracting with alcohol a desiccated curare obtained from a heavy syrup of the bark and stems of *Chondodendron tomentosum*. The alcoholic extract is evaporated to dryness; a sterile filtered solution having a pH of 4.6-4.8 is made and adjusted to a standard potency of 20 units per cubic centimeter. The final solution contains sodium chloride 0.45 per cent and trichlorobutanol 0.5 per cent; sterilized by filtration and its pH again adjusted to 4.6-4.8.

In the preparation of intoxicostein from pure d-tubocurarine chloride crystals, the crystals are obtained from the desiccated curare or from the crude syrup.

Tests and Standards.

Dilute in a large pyrex test tube 0.25 cc. of intoxicostein with 25 cc. of distilled water and add 0.2 cc. of concentrated sulfuric acid and 2 cc. of 1 per cent potassium iodate solution. Mix and warm in a water bath at 50 C. for one-half hour. A yellow color is developed.

The physiologic activity of intoxicostein is determined on rabbits: the provisional unit is equivalent to the potency of 0.15 mg. of d-tubocurarine chloride.

E. R. SQUIBB & SONS, NEW YORK

Intocostein Solution: 10 cc. vials. Each cubic centimeter contains an amount of intoxicostein equivalent to 20 units: sodium chloride 0.45 per cent and chlorobutanol 0.5 per cent as a preservative.

NIKETHAMIDE (See New and Nonofficial Remedies, 1944, p. 330).

The following dosage form has been accepted:

GEORGE A. BREON & Co., KANSAS CITY, Mo.

Sterile Solution Nikethamide 25% W/V: 1½ cc. ampuls.

SULFADIAZINE (See New and Nonofficial Remedies, 1944, p. 178).

The following dosage form has been accepted:

AMERICAN PHARMACEUTICAL Co., INC., NEW YORK

Tablets Sulfadiazine: 0.5 Gm.

DIETHYLSTILBESTROL (See New and Nonofficial Remedies, 1944, p. 417).

The following additional dosage forms have been accepted:

GEORGE A. BREON & Co., KANSAS CITY, Mo.

Tablets Diethylstilbestrol: 5.0 mg.

Caplets Diethylstilbestrol: 5.0 mg.

PENICILLIN (See Supplement to New and Nonofficial Remedies, 1944, p. 18).

The following dosage form has been accepted:

SMITH-DORSEY COMPANY, LINCOLN, NEB.

Penicillin (Sodium Salt): 100,000 Oxford unit vials and 100,000 Oxford unit vials packaged with an accompanying 20 cc. vial of isotonic solution of sodium chloride.

CHAS. PFIZER & Co., INC., BROOKLYN

Penicillin Calcium: 200,000 Oxford Unit bottles.

SULFANILAMIDE (See New and Nonofficial Remedies, 1944, p. 184).

The following additional dosage form has been accepted:

THE SMITH-DORSEY Co., LINCOLN, NEB.

Sulfanilamide (Powder): 5 Gm. vials.

SULFATHIAZOLE (See New and Nonofficial Remedies, 1944, p. 191).

The following additional dosage form has been accepted:

THE SMITH-DORSEY Co., LINCOLN, NEB.

Sulfathiazole (Powder): 5 Gm. vials.

SATURDAY, OCTOBER 13, 1945

Several issues of The Journal have been delayed because of a strike of compositors. The negotiations have been successful and the delayed issues of The Journal will be sent to subscribers as rapidly as possible.

VIRUS DYSENTERY

In 1942 Baker¹ of the Rockefeller Institute, Princeton, N. J., isolated and described a filtrable virus which he believed was the cause of "scours" (pneumoenteritis) in cattle. This disease is recognized by fever, diarrhea and pneumonia; calves less than 1 month of age are particularly susceptible. While the death rate is usually low, the infected calves do not develop normally.

The suspicion that a virus might be the cause of this disease was first voiced by Nagel,² based on his failure to demonstrate bacteria in pneumonic lungs of "scours" calves. His attempts to demonstrate a virus, however, were inconclusive. Only 1 of the 4 calves inoculated with a Seitz filtrate of infected lungs developed evidence of disease, necropsy revealing an intercurrent infection. Similar inconclusive results were reported by Lamont, who was able to produce a disease in calves by simultaneous inoculation with a Berkefeld filtrate of infected lungs plus a hemophilus-like organism previously isolated from the lungs of a diseased calf. He, however, was unable to transfer this dual infection to a second calf.

In 1940 Horsfall and Hahn³ showed that it is often possible to demonstrate a latent infection in apparently normal mouse lungs by serial intranasal inoculations at seven to nine day intervals into normal mice. After the second or third serial passage of the inapparent infection the latent virus acquires a sufficient pathogenicity to produce typical pneumonia. Adopting a similar technique, Baker inoculated groups of virus-free young mice intranasally with 0.05 cc. of a 24 per cent suspension of

pulmonary tissue from "scours" calves. The initial group of mice did not show demonstrable signs or symptoms of disease. By the third serial passage from their apparently normal lungs, however, definite pulmonary lesions were produced, increasing to a lethal pneumonia by the eighth passage. Filtration experiments showed that the infectious agent in the mouse lungs readily passes through a Berkefeld N filter and is therefore presumably a virus.

Intranasal inoculation of calves with suspensions of these infected mouse lungs produced fever (105.8 F) and diarrhea after an incubation period of about three days, followed two days later with signs and symptoms of pneumonia. The diarrheal symptoms ceased about three days later, at which time the temperature fell to normal. Examination of various organs of the infected calves showed that the virus is present only in the lungs and intestine during the first day after onset of the fever. By the third or fourth day the virus is present also in the serum, liver, spleen, kidneys and mesenteric lymph nodes. During convalescence the virus may persist in the pulmonary tissues long after cessation of diarrheal symptoms. Mouse inoculation tests showed that the serum of normal calves will not neutralize this virus. The virus, however, is neutralized by the serum of calves recovered from the experimental mouse virus infection or convalescent from the natural "scours" disease.

A widespread epidemic of a similar disease characterized by diarrhea, nausea and vomiting occurred among the population of Philadelphia in 1943. Reimann and his associates⁴ of Jefferson Medical College made bacteriologic examinations of the stools and pharyngeal secretions of numerous patients. They found no bacteria that would account for the epidemic. About 100 young white mice were inoculated orally, intranasally or rectally with the supernatant fluid from centrifuged human diarrheal stools or with Berkefeld N filtrates from such stools. Pharyngeal washings from the same patients were also inoculated intranasally into mice. A few of the mice became sick and died, showing pneumonitis. Suspensions of the lungs and spleen from such mice were reinoculated by various routes into 100 fresh mice, with negative results. Intranasal inoculations of stool filtrates into 8 calves aged 4 weeks were also negative.

On account of these failures Reimann and his associates resorted to experimentation on student volunteers. Broth garglings and suspensions of diarrheal stools were passed through a Mandel filter. The resulting filtrates were nebulized and passed into a large box into which the volunteer's head was placed for five minutes. Twenty-one students inhaled nebulized stool filtrates. Eleven of them developed typical diarrheal symptoms after an incubation period of less than four

days. In 3 cases the diarrhea was accompanied by a mild nasopharyngitis. Thirty-two students inhaled nebulized filtered garglings. Of these, 17 developed diarrhea without nasopharyngitis. Symptoms did not develop in 6 students who inhaled nebulized patient's serum. In all, 53 per cent of the volunteers who inhaled infectious mists developed typical virus diarrhea, as compared with only 9 per cent of the non-volunteers, who acquired the disease during the same period of time from environmental exposure. Another group of 15 students swallowed 3 cc. of filtered garglings in double gelatin capsules. Five swallowed stool filtrates and 4 patients' serums similarly encapsulated. No symptoms developed from such oral administration.

Considering the circumstances under which the tests were made, the results suggest that the causative agent of the Philadelphia epidemic was an air borne filtrable virus, which entered through the respiratory tract. This "virus dysentery" is presumably similar to air borne "scours" of calves. Detailed studies of the new enterotropic virus are now in progress.

INULIN

Inulin, a vegetable starch consisting of polymerized fructose molecules, has appeared in various roles in human biology. The American Indians used roots and tubers containing inulin as a foodstuff; after the discovery of America these were for some time competitors of the potato in Europe. With the final displacement of the Jerusalem artichoke by the potato in agriculture the interest in vegetables containing inulin vanished for many years. Toward the end of the last century they were recommended as substitutes for ordinary starch and sugar in the dietary control of diabetes mellitus. However, when it was shown that the human body does not possess any efficient mechanism for metabolism of this type of starch, the medicinal interest in inulin waned. It reappeared in 1935 on the discovery that inulin parenterally introduced is excreted exclusively through the glomeruli.¹ Inulin clearance tests have been used since then in clinical and experimental work to ascertain the function of glomerular filtration of normal and diseased kidneys and to study the action of numerous endogenous and exogenous agents, particularly those with diuretic effects, on the renal function.

Barnett² found that infants 4 to 9 days old have a glomerular filtration rate of inulin from 20 to 40 per cent of that of the adult and attributed this low renal function of the newborn to incomplete development of the glomeruli. The inulin clearance is reduced

on a functional renal basis during the antepartum period of women with preeclampsia and hypertension,³ and on an anatomic basis in persons with chronic nephritis.⁴ The colorimetric methods for the quantitative determination of inulin in the blood and urine are now sufficiently simple, reliable and accurate, requiring in part not more than 0.2 cc. of blood for the single test, to make inulin clearance tests practicable in the average hospital laboratory.⁵

The preparation of a chemically pure solution of inulin, free from pyrogen, levulose and the water insoluble type of inulin, is at present the main difficulty in the way of the practical clinical use of this important renal function test. The intravenous injection of impure solutions of inulin may give rise to severe untoward reactions. Inulin solutions properly prepared are apparently harmless even when given in large amounts in single or repeated doses over prolonged periods.⁶ Experiments by Hueper⁶ have thrown an interesting light on the development of colloidoclastic phenomena in the blood following the intravenous injection of solutions of colloidal substances. It was found that, in contrast to the reactions following the introduction of solutions of several macromolecular carbohydrates with molecular weight above 30,000, no such reactions occurred on the injection of solutions of inulin, which possesses a molecular weight of 3,000 to 5,000 and which, as stated, is readily filtered through the glomeruli, while the larger molecular carbohydrates are at least in part retained by the glomerular filter.

Current Comment

ARMY MEDICAL OFFICERS IN THE VETERANS ADMINISTRATION

Apparently President Franklin Delano Roosevelt, toward the end of 1944, sent a directive to the Army and Navy medical departments which compelled them to assign a certain number of their officers to the Veterans Administration for use in veterans' hospitals. The number of physicians now so employed approximates 1,700 medical officers out of a total of 2,300 physicians in the Veterans Administration. Day after day letters are being received from these men complaining bitterly of their inability to obtain their release from this service either on the basis of a point system or by any other technic. Apparently the Veterans Admin-

istration requires at least 3,600 physicians to carry on its present activities, and it has only 2,300, of whom only 600 are men regularly in the Veterans service. Inquiries made directly of the Army and Navy medical departments do not indicate that the officers there on duty have any solution for the problem. They urge that release of the medical officers from the Veterans Administration would make it necessary to retain the wounded in army and navy hospitals instead of releasing them to the Veterans Administration and that it would then be necessary to retain in the armed forces many medical officers who under present circumstances can be released. The letters from the physicians who have been assigned to the Veterans Administration complain bitterly that they have not been assigned in most instances to care of the sick but that the majority of the work given them is the keeping of records, with routine examinations for the determination of the extent of disabilities. Retention in this type of medical service of physicians who volunteered their services to the nation in time of war, with the understanding that they would be actively engaged in military medical service, is contrary to common justice and apparently a violation of the mutual obligation that developed on enlistment of the officer in a branch of the military service. The resentment and bitterness felt by these men against their government and against the officers of the armed forces who assigned them to these positions would seem to be well warranted. There has been disregard of their rights. True, the Congress has not yet declared the emergency at an end and these officers are still bound by their oath on being commissioned in either the Army or Navy medical departments. Nevertheless they feel that they are being held through a subterfuge in a service for which they did not enlist and in which they could not now be retained except by a tacit disregard of their rights.

LORD DAWSON AND THE POSTMORTEM EXAMINATION

Lord Dawson, who was physician to the London Hospital and twice president of the British Medical Association, died in London on March 7. In his will he left specific directions relative to postmortem examination. Lord Dawson felt that a postmortem examination should be made on his own body unless conditions arising out of the war made this too difficult or unless the doctors who were in attendance on him in his last illness thought that any service to knowledge could not follow such an examination. Here are his own words:

I do this because I think the public do not sufficiently realise the importance of post-mortem examinations being made and the advantages to knowledge and therefore to future generations which will accrue. We do not hesitate to have operations performed on our bodies when we are alive and circumstances require it. Why then should we mind operations (which are done with the same care, the same gentleness, and, I may add, the same reverence) being done to our bodies when we are dead? Surely this is rightful service which the dead should give to the living. The benefit of such service to the living is very great.

The message should be an inspiration to every physician and particularly to interns and residents in our great hospitals on whom falls, in most instances, the responsibility for securing consent to postmortem examinations on patients who die in the hospital.

THE INTERVIEW WITH NARCOSYNTHESIS

Hart and his associates¹ disagree with Grinker and Spiegel in differentiating the narcotic effects of barbituric acid derivatives as distinct from hypnosis. They feel that interview with the use of hypnotic drugs is largely another hypnotic therapy. In fact, barbiturates facilitate hypnosis for many subjects. These authors prefer intravenous sodium amytal to pentothal because with the former the milder levels of diminished awareness may be prolonged. There is also no difficulty with "hangover" effects from sodium amytal if sufficient caffeine with sodium benzoate is used at the end of the treatment. They have also observed that one may suggest a selective recall of actions and discussions under amytal narcosis, as with hypnosis, more readily than with pentothal narcosis, largely because the lighter levels of narcosis are better controlled. In the interview with sodium amytal 1 Gm. of sodium amytal is dissolved in 30 or 40 cc. of distilled water and is placed in a large syringe with a small gage intravenous needle. Caffeine with sodium benzoate $7\frac{1}{2}$ grains (0.5 Gm.) should always be at hand in a hypodermic syringe in case of untoward reactions or too deep a narcosis. The caffeine is injected subcutaneously at the completion of the interview in order to assure one against prolonged deep narcosis and to facilitate the return of awareness. The sodium amytal should be administered very slowly, 1 grain (0.06 Gm.) or less per minute. The interview consists in strong and repeated suggestions, reconstructing a combat situation. In the treatment of more than 500 cases they had only 1 instance of respiratory arrest, and that took place after 4 grains (0.26 Gm.) of sodium amytal. However, the administration of 15 grains (1 Gm.) of caffeine intravenously was followed by a prompt return of respiration. The interview with amytal was found to be effective as therapy for combat cases of recent origin, for recovery of forgotten or painful battle experiences and for the reliving of emotionally traumatic situations. Battle dreams, sleeplessness, irritability, associability and negativistic reactions subside promptly after an effective treatment. More lasting effects can be established by interpretation of this material during the next two or three days after the treatment. With the aid of this only two or three treatments were as a rule necessary. The sodium amytal interviews were found particularly valuable where faking or conscious distortions were suspected. This therapy was also useful in the treatment of conversion symptoms, particularly in demonstrating functional limps and backaches. Skill in the employment of amytal, the authors assert, is not difficult to acquire. The interview with hypnotic drugs is another valuable and rapid technic for diagnosis and treatment in psychiatric states.

MEDICINE AND THE WAR

MEDICAL PROBLEMS OF THE VETERANS ADMINISTRATION

MAJOR GENERAL PAUL R. HAWLEY

In undertaking the reorganization of the Medical Service of the Veterans Administration, the Acting Surgeon General is anxious to have the approval and support of the medical profession; only in this way can the program succeed.

While, so far as the patient is concerned, medical care is one complete function, it must be divided administratively into his hospitalization and his outpatient treatment. In the majority of cases, perhaps, complete medical care is furnished by outpatient treatment; but there are many other cases in which outpatient treatment is either preliminary to hospitalization or supplements the care given in hospitals.

It is impossible to undertake the medical care of the veteran with a permanent, full time, paid corps of medical persons. That was tried when the proportion of doctors among the population was higher than it is now and perhaps higher than it will be for the next ten or fifteen years. It failed for several reasons: first, because it was impossible to get the proper caliber of medical personnel for the compensation given them; second, because hospitals were built in inaccessible places, where their staffs lost touch with the advance in medicine, no provision having been made for graduate training and for keeping these physicians in touch with medicine and surgery; third, because no inducement was given to physicians who entered the service to improve themselves of their own volition.

There are but few physicians in the Veterans Administration who have been certified by a specialty board. Occasionally, however, one is encountered; and since he has accomplished this distinction without the encouragement of his service, he is to be admired.

General Bradley has elevated the status of the Medical Service to that of a major service, responsible directly to the Administrator of Veterans' Affairs. He is fully alive to the great medical problems confronting his administration and will support every effort to improve his medical service, including encouragement of professional study.

The requirement at the present time is for about 3,600 physicians. There are in the administration 2,300, of whom 1,700 are on loan from the Army and the Navy. If the entire load of only our hospitals and of physical examinations is to be carried by full time physicians, 1,500 more are needed. The large majority of those lent by the Army and the Navy are unhappy and dissatisfied, for very evident reasons. Obviously, therefore, the situation is critical. It is impossible to weather this storm with the means at our disposal at the moment.

In asking the assistance of the civilian profession, the present administration wants to do everything it can to make the service that they will give worth while to them individually and to the profession as a whole. The pay offered the physician probably will not be as much as his service would command outside. However, a study is being made of the scale of salaries and fees, with the idea of revising them upward so that they will more nearly approach what the services are worth. If it is objectionable to the civilian profession to become an employee of the hospital, then we must have two accounts—one for the hospital and one for the physician.

Most of the leaders in the profession are interested in teaching, but the facilities for graduate training of physicians do not seem to be adequate in certain places in the country; so the administration would like to have close liaison with teaching institutions.

Over and above the financial return and the opportunities for teaching, there is little to offer the well qualified physician whom it is hoped to interest. Consequently the administration no doubt will have to appeal to the unselfishness of the profession,

realizing that it will contribute more than it receives and asking it to charge the deficit to a fine public service rendered in the care of the veteran.

In the outpatient care—and by that term is meant any care or treatment given to the veteran who is not actually admitted to a hospital—it is hoped to get something started very rapidly.

Care must be used in appointing as consultants only those physicians who are highly regarded by the rest of the profession so that these appointments will be a mark of quality. We want no one to be ashamed to say that he has been appointed a consultant by the Veterans Administration. It is proposed to extend this principle to the small communities where physicians must be designated to take the outpatient service. It is a matter of law that the veteran go to a veterans' physician, but there is nothing in the law to say that all qualified physicians in a community cannot be designated to take care of veterans.

The idea should be conveyed even to the smallest component society of the American Medical Association that here is a public duty which should be considered seriously, and that the local society must bear this in mind in its recommendations.

In regard to clinics for neuropsychiatric patients: There are not enough psychiatrists, especially in the smaller communities, to establish mental hygiene clinics. Contact has been made with the American Psychiatric Society to try to offer some facilities for a program for the training of doctors in this specialty. In the smaller community the administration may have to depend, not on fully qualified psychiatrists, but on family physicians who are given an opportunity to take short courses in psychiatry.

The paper work, that is, the filling out of forms connected with the care of the veteran, seems to frighten the physician. Perhaps a committee could simplify these procedures so as to make it less burdensome for the man who undertakes the work.

Another great obstacle is the policy, fostered and encouraged by several groups interested in the veteran, that the most essential thing in the care of the veteran is to keep him close to home. When one speaks of moving a veteran away from his home to give him better care, one encounters strenuous objection. This would make specialized care of the veteran impossible because there are not enough specialists in many areas to give the kind of care which the veterans should have. Perhaps the best person to reeducate the family on this is the family physician. He can do much to persuade the family to consent to moving the veteran for better specialized care.

General Bradley asked Congress to postpone action on the bill to create a permanent medical corps for the Veterans Administration until he could study it, and the draft has been completely rewritten. At first I was opposed to any permanent corps, but I have had to compromise my own thought in the matter. The Veterans Administration has thousands of beds in inaccessible places which it will have to use, and it will no doubt have to have a permanent corps to staff these hospitals. It is hoped that such mistakes in locations will not be repeated. Then there is a certain kind of administrative work on rating boards for which it is almost impossible to procure part time service. Full time people for this work probably will be necessary, but the corps will not be anywhere near large enough to carry the entire veterans' load, and no attempt will be made to build up a large permanent organization.

The general provisions of this bill have been limited to medical people, including only one small corps of allied professional people, such as the Public Health Service has. Pathologists, chemists and research workers may be required in addition to physicians, dentists, nurses, physical therapists, occupational therapists and a small group of pharmacists that have been included.

The promotion of people in the allied professions and the allocation of grades to them have been made comparable to the amount of training it takes to qualify them for their profession. The scale of pay and retirement privileges are the same as for the Army, the Navy and the Public Health Service. One additional feature has been added: When an officer has been certified by one of the specialty boards and has been rated as a specialist by the Surgeon General, his pay shall be increased 25 per cent over that to which his grade and length of service would entitle him. This is to encourage professional advancement.

One great trouble with the Veterans Administration has been its centralization. The administrator is now decentralizing the

administration to thirteen districts. There must be a medical staff in each district. There the requirement is for full time people. The principal duties of the medical staff of the districts is the supervision of the medical service, liaison with the civilian profession and appointment of proper consultants. This phase of the reorganization will probably take about two years. One district at a time will be established.

I should like to see veterans' hospitals built in such a way that, as their need for the care of veterans decreases, they can be fitted into the need of the people as a whole. In the years to come they could perhaps be turned over to communities. I am in favor of the care of the veteran in the existing civilian institutions to the greatest possible extent.

NAVY

NAVY REDUCES POINT SCORE FOR MEDICAL OFFICERS

Four thousand medical officers of the Naval Reserve will become eligible for separation to inactive duty by Jan. 1, 1946 under provisions of an ALNAV recently signed by the Secretary of the Navy. The new order, effective November 1, establishes a critical score of 53 points for male medical officers, a reduction of 7 points from the figure in effect since September 15.

Present strength of the Navy Medical Corps (Regulars and Reserves) is 13,700. This is exclusive of a relatively small number of active officers on the retired list, interns, women medical officers and male officers assigned to duty with the Veterans Administration. All but approximately 2,000 are in the Naval Reserve.

Under the 60 point score discharge system effective since September 15 it was estimated that 1,700 medical officers would have been eligible for discharge by January 1. Lowering of the score will increase this total by nearly 150 per cent.

HOLD MEETING AT NAVAL HOSPITAL

Rear Admiral W. J. C. Agnew (MC), U.S.N., assistant chief of the Bureau of Medicine and Surgery, who is making an inspection tour of West Coast activities, attended the recent autumn meeting of the Northern California Society of Neurology and Psychiatry at the United States Naval Hospital, San Leandro, Calif.

Capt. W. F. Kennedy (MC), U.S.N., medical officer in command of the hospital, opened the one day meeting and conducted a hospital inspection which featured a demonstration of rehabilitation methods, directed by Lieut. Comdr. F. J. Hamilton (MC), U.S.N.R.

Presided over by Capt. Lawrence R. Gowan (MC), U.S.N.R., chief of the Neuropsychiatry Department, the evening program was given over to preliminary reports on research studies in epilepsy by Lieut. Comdr. Knox H. Finley (MC), U.S.N.R., Lieut. Comdr. Thomas W. Richards, Hospital Corps, U.S.N.R., and Lieut. Charles M. Jessico (MC), U.S.N.R. Etiologic Factors in the Production of the Neuroses of War was discussed by Comdr. George H. Gerow (MC), U.S.N.R.

NAVY TO RELEASE NURSES

Under the Navy's point system, about 2,000 Naval Reserve nurses will be released by February 1946, according to Capt. Sue S. Dauser, U. S. N., superintendent of the Nurse Corps.

The V-J day strength of the Nurse Corps was 11,000. Already 800 nurses with the 35 points required to be eligible for discharge are beginning to move through the five personnel separation units for Waves and Navy nurses, situated at Washington, D. C., New York, Memphis, Tenn., Great Lakes, Ill., and San Francisco. By September 1946 it is estimated that about 7,000 will have been released under the point system.

Captain Dauser also announced that as soon as the patient loads diminish sufficiently the Navy will consider the release of all married nurses, regardless of the number of points. Approximately 700 nurses would be affected by this ruling.

NAVY AWARDS AND COMMENDATIONS

Lieutenant Commander Ernest A. Zinke Jr.

The Bronze Star was recently awarded to Lieut. Comdr. Ernest A. Zinke Jr., formerly of Holtville, Calif., "for outstanding work in the care of the injured when a heavy cruiser was attacked by enemy planes in the Southwest Pacific." Dr. Zinke graduated from the College of Medical Evangelists, Loma-Linda, Calif., in 1938 and entered the service May 15, 1941.

Lieutenant James W. Tedder

Lieut. James W. Tedder, formerly of New Orleans, was recently awarded the Bronze Star for heroic and meritorious service to survivors of a torpedoed, sunken ship in Lingayen Gulf during the invasion of Luzon in the Philippines last January. Dr. Tedder graduated from Tulane University of Louisiana School of Medicine, New Orleans, in 1932 and entered the service Jan. 2, 1943.

Lieutenant Commander Alvin L. Mathis

Lieut. Comdr. Alvin L. Mathis, formerly of Elmhurst, Ill., was recently awarded the Silver Star. He has served with the First Marine Division in the Pacific and was cited for intrepidity and initiative in administering to and evacuating wounded from beyond the front lines on Peleliu last September 17. Dr. Mathis graduated from the University of Illinois College of Medicine, Chicago, in 1930 and entered the service March 26, 1943.

PUBLIC HEALTH SERVICE.

RELEASE OF MEDICAL OFFICERS FROM THE PUBLIC HEALTH SERVICE

The Public Health Service has adopted a point system to determine the order of release of reserve medical officers who desire to return to civilian practice. Points will be calculated on the following basis:

Each year of age	½ point
Each month of service since June 30, 1939	½ point
Each month of service outside the continental United States	½ point
Dependents (regardless of number)	10 points

Physical disabilities, individual hardships and urgent need for an officer's services in a community, medical school, teaching hospital or health department will also receive consideration.

As the war activities of the Public Health Service have decreased, release of officers has been effected. Those with the greatest number of points have received and will continue to receive prior consideration. The rate of future releases will necessarily be gradual over the next few months because of the work of the service in connection with demobilization and of the necessity of maintaining activities which will be carried at a peacetime level. At the present time there are only 987 reserve medical officers on active duty, and it is anticipated that practically all who desire will be separated from the service not later than Sept. 1, 1946.

ORGANIZATION SECTION

Washington Letter

(From a Special Correspondent)

Oct. 8, 1945.

Praise for Monmouth County, N. J., Medical Plan

Major Gen. Paul R. Hawley, acting Surgeon General of the Veterans Administration, has expressed his gratification over the Monmouth County, N. J., plan of cooperation with the Veterans Administration to provide medical service for ex-GIs in doctor-nurse shortage areas. He urged other counties and communities to work out their own plans for cooperating with the agency to serve the returning veterans. The Monmouth plan was presented by Dr. W. G. Herrman, past president of the Medical Society of New Jersey, and Dr. Granville Jones, president of the Monmouth County Medical Society. According to the plan the Veterans Administration will agree to certify all county medical society members to treat veterans. The executive committee of the society will select three screening clinics, each made up of five specialists, and all county veterans desiring medical treatment will appear before one of the clinics. The kind of medical service required will be diagnosed and, except for unusual ailments, veterans will be allowed to choose their doctors. Most veterans, it is expected, can be treated as outpatients or at the home or in a county hospital, but some will require protracted hospitalization in veterans' hospitals. A special disciplinary board will pass on complaints by veterans, physicians or Veterans Administration representatives. These and other features of the plan will enable the veteran to be treated as a member of his community rather than as a segregated individual. He will receive medical and hospital care a reasonable distance from home, with medical fees and expenses paid by the administration. Under the present Veterans Administration setup the outpatient service hardly exists, and a veteran must remain in an administration facility to get treatment. For three months the screening committee, doctors and county hospitals will donate their services to the agency. The fixed fee schedule will be accepted by participating doctors until the experiment is accepted as an official activity of the Veterans Administration. The present fee is regarded as too low.

Revamped Hospital and Health Center Bill Prepared

A revised bill providing federal aid for hospital and health center construction is ready for approval by the Senate Education and Labor Committee. Originally introduced by Senator Hill (Dem.) of Alabama and Senator Burton (Rep.) of Ohio, it was rewritten by the committee to provide federal grants totaling \$75,000,000 a year for five years, and to appropriate \$5,000,000 for a survey of national hospital and health center needs. Funds would be distributed on a population and per capita wealth basis. Fifteen of the poorest states, mostly in the South, would get 47.8 per cent of the funds, sixteen middle bracket states 18 per cent and eighteen of the wealthiest states 31 per cent, with territories allotted 32 per cent. Originally it was planned to match funds for public and nonprofit hospitals on a 50-50 basis. The federal contribution as it is now planned would be 33 per cent for richest states and 75 per cent for the poorest.

Continued Discussion on Improvement of Artificial Limbs

Considerable discussion continues to be devoted in Congress to improvement of artificial limbs for servicemen. The Veterans Administration reveals that it is organizing a new section to study the problem of providing the best artificial limbs for war amputees, headed by Walter M. Bura of Miami, Fla., an amputee and at present civilian adviser to the Surgeon General. Meantime the agency, through Col. J. C. Harding, acting assistant to the Surgeon General, has answered criticism that the agency was paying \$125 for artificial limbs which it costs \$35 to make. On top of all this members of the House Subcommittee to Investigate and Aid the Physically Handicapped have

agreed informally to recommend to Congress that research on artificial limbs be undertaken by a single federal agency. It is expected to recommend in the next fortnight an appropriation of around \$500,000 annually for federal research on artificial limbs and creation by the artificial limb industry of a fair trade code enforceable by the Federal Trade Commission. Also expected is a recommendation from the committee that all skilled artificial limb craftsmen be released from the armed forces.

Army Ponders Fate of 7,959 Medical Students

The Navy has demobilized its medical students, ending its medical training program with the war, although students were notified they would be commissioned and placed on reserve status if they wished to continue studies and graduate at their own expense. However, the House Military Affairs Committee is now concerned over some 7,959 medical students whose studies are being continued at Army expense. The committee is faced with these alternatives: Should Congress require them to stay in the Army long enough to complete their free education or long enough to pay for it or should the students be demobilized to a pay as you go status? The Army has ordered that the War Department carry on the training program, in which 300 new students were enrolled this month. About 10,000 have graduated since the program started. All enlisted as privates, and school fees and expenses were paid. They get subsistence pay of \$90 a month, which adds up to around \$9,000,000 a year for 7,959 students. With summer vacations and holidays omitted, they finish a four year medical course in thirty-six months.

Veterans Administration Seeks Aid on Claims

Now under negotiation is a plan whereby the medical profession would assist the Veterans Administration in medical work involved in clearing up a heavy backlog of veteran claims. As the full force of war casualties is now hitting the agency, more than a million pension claims have already been filed. On September 20, 73,453 veterans were under hospital treatment and 9,610 were receiving domiciliary care. The hospital figures had been climbing slowly since Jan. 31, 1942, when 58,576 patients were listed.

Medical Legislation

Health Programs for Government Employees

The House has passed H. R. 2716 to provide for health programs for government employees. During the discussion of this bill on the floor of the House, numerous questions were raised concerning the relationship of this bill to proposals to socialize the practice of medicine. After the assurance had been given that the bill had no relation whatever to such proposals, it was passed.

Miscellaneous

Another bill to provide for the general welfare by enabling the several states to make more adequate provision for the health and welfare of mothers and children and for services to crippled children has been introduced by Representative Patterson, California, H. R. 4059. It is identical with the Pepper bill, S. 1318.

Representative Priest, Tennessee, has introduced H. R. 4110, proposing that no new graduate or student nurse shall be admitted for training or courses under the act providing for the training of nurses after October 15, 1945, and that not more than 30,000 student nurses shall be admitted for training after June 30, 1945 and prior to Oct. 16, 1945.

H. R. 4070, introduced by Representative Spence, Kentucky, will provide for water pollution control activities in the United States Public Health Service. It is pending in the House Committee on Rivers and Harbors.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Dr. Graves Honored.—On September 14 the faculty of the Medical College of Alabama, Birmingham, gave a farewell dinner in honor of Dr. Stuart Graves, who is now dean emeritus and professor of pathology emeritus, and Mrs. Graves. Dr. Ralph McBurney, professor of bacteriology, and oldest full time professor on the Tuscaloosa school faculty in point of service, was toastmaster. Dr. Graves, who was presented with a gold mounted fountain pen and pencil set, will not end his work in medical education with the transfer of the faculty of students of the School of Basic Medical Sciences to the Birmingham school. Although approaching the age of retirement he will continue to occupy an office on the ground floor of Nott Hall, which is being remodeled and renovated for the department of biology. He will act as director of admissions for the Medical College of Alabama and as adviser to premedical students on the university campus. At the request of Dr. Roy R. Kracke, dean of the new four year Medical College of Alabama (*THE JOURNAL*, Aug. 11, p. 1116), Dr. Graves will also be editor of the *Medical Bulletin* and act as chairman of the committee on student welfare in the Medical College of Alabama, commuting at times to Birmingham. He has also been made a member of the university committee on premedical studies and the university committee on student health.

FLORIDA

Dr. Griffiths Goes to Haiti.—Dr. Thomas H. D. Griffiths, former Dade County health commissioner, has been appointed director of health for the republic of Haiti, according to the *Miami Herald*. He was scheduled to leave September 22 by plane for his new post. Before coming to Dade County in November 1942 Dr. Griffiths had retired from the U. S. Public Health Service after thirty years of service. He has been living at Fort Lauderdale for the past year.

Henry Hanson Honored.—More than 200 employees of the state board of health gathered September 15 to present to Dr. Henry Hanson a finger ring containing three diamonds. Presentation was made by Dr. George A. Dame, Jacksonville, director of the state bureau of local health service. The gift was made possible by members and employees of the state board of health and marks the retirement of Dr. Hanson as state health officer (*THE JOURNAL*, September 22, p. 291).

District Medical Meetings.—The Florida Medical Association announces the meeting schedule of the following district societies: Northwest Medical, Tallahassee, October 15, *Floridan Hotel*; the Northeast Medical, Ocala, October 16, *Highlands Hotel*; Southwest Medical, Tampa, October 17, *Hillsboro Hotel*; Southeast Medical, Miami, October 18, *Coral Gables Country Club*. Activities of current interest of the profession will be discussed by the various officers of the state medical association.

MINNESOTA

Supreme Court Voids Medical Board.—The Minnesota Supreme Court recently declared unconstitutional a provision of the workmen's compensation law, passed by the 1943 legislature, which provided for creation of a medical board to determine controverted or disputed medical issues in occupational disease cases. The section voided by this action of the Supreme Court provided for a medical board of three doctors of medicine selected from a panel of fifteen nominees chosen by the dean of the University of Minnesota Medical School, Minneapolis, the council of the Minnesota State Medical Association and the governor of Minnesota. The medical board was authorized to examine the employee and file its "findings and conclusions" with the industrial commission, signed by all the members of the board participating. The "findings" were to state, among other things, whether the employee had been afflicted with an occupational disease within the provisions and definitions of the occupational disease law. Based on the premise that there were no provisions under the law that a transcript of the evidence on which the board's findings were based be filed with its report, the Supreme Court ruled the medical board as set up to be unconstitutional for the reason

that it denied a claimant for compensation the right of full review guaranteed him by the workmen's compensation law under the "due process" clause in the statute. According to *Minnesota Medicine*, with the elimination of the medical board the statute, as it now stands, will permit the industrial commission or a referee within the commission, according to established practice, to take testimony of one physician for each party on the question of occupational disease. If the commission or the referee hearing such evidence is unable to determine whether a claimant suffers from an occupational disease within the provisions of the statute, then the commission or the referee conducting the hearing may, on his own motion, designate a neutral physician in good standing to examine the injured person and report his findings, which, in addition to other evidence, will be weighed by the commission or referee as competent evidence in determining this issue.

OHIO

James Doull to Direct International Health Relations.—Dr. James A. Doull has resigned as Elisabeth Severance Prentiss professor of public health at Western Reserve University School of Medicine, Cleveland, effective March 31, 1946, to join the regular corps of the U. S. Public Health Service and be in charge of international health relations in the Office of the Surgeon General. The appointment is said to be in anticipation of the establishment of a new national health organization in the near future to take over and extend the functions of the health sections of the league of nations. The resignation vacates the chair in public health established recently in the school of medicine by the university with the support of a bequest by the late Mrs. Elisabeth Severance Prentiss. Dr. Doull had previously been head of the department of hygiene and bacteriology, now divided into the department of public health and the department of microbiology (*THE JOURNAL*, July 28, p. 963). Dr. Doull has been at Western Reserve University since 1930.

UTAH

State Medical Election.—New officers of the Utah State Medical Association include Drs. Ray T. Woolsey, Salt Lake City, president; Lester A. Stevenson, Salt Lake City, president-elect, and David G. Edmunds, Salt Lake City, secretary.

WASHINGTON

Edward Turner Named Dean of New Medical School.—On September 29 Dr. Edward L. Turner, Bradford, Pa., was appointed dean of the new Medical School of the University of Washington (*THE JOURNAL*, February 3 p. 288; April 21, p. 1067). He is expected to start his work of organizing the medical school about December 1; he will also make plans for the proposed school of dentistry. Dr. Turner graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1928. He was associated with the American University of Beirut, Syria, for about ten years as head of the department of physiology, head of the department of medicine and later as acting dean of the medical school. From 1938 to 1944 Dr. Turner was president of the Meharry Medical College, Nashville, having served earlier as professor and head of the department of medicine.

GENERAL

George Dunham Resigns.—Dr. George C. Dunham has resigned as president of the Institute of Inter-American Affairs because of ill health. He will continue his service with the institute as chairman of the board of directors. Col. Harold E. Gotaas, S. C., A. U. S., formerly executive vice president of the Institute of Inter-American Affairs and director of the Division of Health and Sanitation, will succeed Dr. Dunham. Col. John D. Yeagley, M. C., A. U. S., associate director of the Division of Health and Sanitation of the institute, has been appointed director to succeed Colonel Gotaas.

Medical Illustrators Meeting.—Officers of the Association of Medical Illustrators met in New York recently to discuss certain proposed activities and the final draft of the new constitution and by-laws. The meeting was held in conjunction with the session of the Biological Photographic Association. Elon Clark of Duke University School of Medicine, Durham, N. C., is the chairman of the fifteen member board of governors set up by the Association of Medical Illustrators. Mr. Tom Jones, University of Illinois College of Medicine, Chicago, is president and Mr. Willard C. Shepard, Philadelphia, vice president; Muriel McLatchie, Boston, secretary and Elizabeth Brodel, New York, treasurer (*THE JOURNAL*, August 4, p. 1040).

Reduced Fares to Ophthalmology Congress.—The Pan American Airways System is offering a 15 per cent reduction on fares to delegates attending the Pan American Congress of Ophthalmology meeting at Montevideo, Uruguay, November 26-December 1 (*THE JOURNAL*, September 15, p. 224). The fare from Miami to Montevideo via the East Coast is \$486 one way, \$874.80 round trip, and via the West Coast \$504 one way, \$907.20 round trip. For any delegates who may be interested in making a circle trip around South America the fare will be \$891. All these fares are subject to the 15 per cent United States transportation tax. However, as already mentioned, these fares are also subject to 15 per cent discount.

Hospital Review to Substitute for National Meeting.—A series of publications containing data of both contemporary importance and lasting interest to hospital administrators and the hospital minded will take the place of the 1945 convention of the American Hospital Association. Entitled in its entirety as "The 1945 Hospital Review," the series will deal with current developments in problems of hospitals and outlooks for the future. To be distributed in October, the first work of the series, "The Individual Hospital" will be composed of three book sections and a preface. The book sections include "Measuring the Community for a Hospital," "Organization of Governing Board and Medical Staff" and "Administrative Aspects of Hospital Construction," all prepared by Dr. Warren P. Morrill, Chicago, research director of the association. The preface to these sections will contain contemporary definitions of the hospital in relation to the physician, the trustee and the administrator. The definitions are being contributed by recognized spokesmen in these fields. "Economic Issues Facing Hospitals," treated in six book sections, will comprise the second in the series. Public leaders and officers and headquarters personnel of the association will prepare material on economic issues facing hospitals, U. S. Senate bill 191, government payment for hospital care of indigents, care of the veteran in community hospitals, the Blue Cross prepayment plans and the Commission on Hospital Care. The third publication, "Activities and Business of the American Hospital Association," will include addresses by the outgoing and incoming presidents, Drs. Donald C. Smeizer, Philadelphia, and Peter D. Ward, St. Paul, respectively, in addition to reports of the association's bodies and a summary of its activities during the year. Transactions of the house of delegates meeting in Chicago, November 5-7, will also be published in the third book.

Tenth National Assembly of College of Surgeons.—The tenth (Victory) National Assembly of the United States chapter of the International College of Surgeons will be held December 6-8 at the Mayflower Hotel, Washington, D. C., under the general chairmanship of Dr. Custis Lee Hall, Washington. The speakers will include:

- Dr. Garnet W. Ault, Washington, D. C., Ulcerative Colitis.
- Lieut. Col. Wilbert H. McGaw, M. C., Pneumographic Differential Diagnosis in Internal Derangement of the Knee Joint.
- Capt. Winchell M. Craig (MC) and Capt. Joseph S. Barr (MC), Recounting of Spinal Cord Injuries.
- Dr. Edgar Davis, Washington, D. C., Tumors of the Lung.
- Dr. Charles Stanley White, Washington, D. C., Amino Acids in Surgery.
- Dr. J. Ross Veal, Washington, D. C., Circulatory Disturbances of the Lower Extremity.
- Dr. Elmer Hess, Erie, Pa., Conservative Renal Surgery.
- Dr. Albert A. Berg, New York, Terminal Ileitis.
- Lieut. Col. Benvenuto R. Dino y Regidar, M. C., Philippine Army, Salvaging Medical Education in the Philippines.
- Dr. Emil J. C. Hildenbrand, Washington, D. C., Refrigeration Anesthesia.
- Dr. Roland M. Klemme, St. Louis, Major Neuralgias.
- Dr. Moses Behrend, Philadelphia, Phlebitis, Embolism and Thrombosis.
- Drs. James W. Watts and Walter Freeman, Washington, D. C., "Psycho-surgery" for the Relief of Unbearable Pain.
- Dr. Clark D. Brooks, Detroit, Problems in Gallbladder Surgery.
- Major General Paul R. Hawley, M. C., Washington, D. C., Surgery in the European Theater of Operations.
- Lieut. Col. Brian B. Blades, M. C., Washington, D. C., Recent Advance in the Treatment of Chronic Empyema.
- Dr. Eduardo Cáceres, Lima, Peru, Cancer of the Larynx.
- U. S. Senator Allen W. Bartley, Washington, D. C., The World Today.
- Dr. James C. Masson, Rochester, Minn., Cancer of the Uterus: When Surgery, When X-Ray?
- Dr. Edward V. M. Martin, St. Louis, Surgery of the Thyroid Gland.
- Dr. Frank E. Adair, New York, Carcinoma of the Breast.

Other speakers on the program will include Col. Alfred R. Shands, M. C., and Col. Leonard T. Peterson, M. C. Dr. Herbert Acuff, Knoxville, Tenn., is president and Dr. Louis J. Gariopy, Detroit, secretary of the United States chapter of the college.

Certification in Allergy.—The American Board of Pediatrics at its meeting in New York in April took final action establishing certification in allergy as a subspecialty of pediatrics. Certification in pediatrics by the American Board of Pediatrics is a prerequisite for such certification in allergy. Those who are already specialists certified by the pediatric board and who wish to be certified in allergy must make formal application to the secretary of the American Board of Pediatrics, Dr. C. Anderson Aldrich, 115½ First Avenue S.W., Rochester, Minn. Those who are not yet certified in pediatrics who desire certification in allergy as well should indicate this in their application to the board of pediatrics as examination in the two subjects may be held at the same time. The application fee for certification in allergy will be \$25 in addition to the application fee for certification in pediatrics. An Advisory Committee on Allergy has been appointed to act with the board of pediatrics in all matters pertaining to the selection and examination of applicants for subspecialty certification. This committee is identical with the Advisory Committee on Allergy of the American Board of Internal Medicine. The present members of this committee are Drs. Harry L. Alexander, St. Louis; Robert A. Cooke, New York; Leslie N. Gay, Baltimore; Harry L. Huber, Chicago; George Piness, Los Angeles, and Francis M. Rackemann, Boston. In December of this year Dr. Oscar M. Schloss, New York, will be appointed as a pediatric member of this advisory committee to take the place of the retiring member. The Advisory Committee on Allergy has already outlined the requirements for applicants who desire examination in the subspecialty of allergy as follows:

Two years, full time, in a satisfactory allergy clinic and its hospital (including training both in allergy and in pediatrics) or

One year, full time, in the allergy clinic and its hospital and two additional years of full attendance on such an allergy clinic and its activities or

Five years, full attendance, on such an allergy clinic and its activities or

Special training under qualified preceptors, solely or in combination with aforementioned types of training, and such other training as might be felt adequate to prepare an individual for the practice of allergy.

It was further the opinion of this committee that clinics for such training should fulfil the following qualifications:

They should be in hospitals that have been accepted by the Council on Medical Education and Hospitals of the American Medical Association and by the American Board of Pediatrics for training and certification in pediatrics and for residencies in pediatrics or medicine.

The director of the allergy clinic should be a specialist certified in allergy by the American Board of Internal Medicine or the American Board of Pediatrics.

When accepted, the certified specialist will receive from the American Board of Pediatrics a certificate in allergy and will be listed as a specialist in allergy in the official directory of the Advisory Board for Medical Specialties.

LATIN AMERICA

Health Activities in Latin America.—*School of Hygiene Dedicated.*—Dr. Marcos Charnes writes that the School of Hygiene of Chile was organized in 1944 through the cooperative efforts of the University of Chile, the Public Health Service of Chile, the Bacteriologic Institute of Chile and the Rockefeller Institute. A news item in *THE JOURNAL*, July 28, page 965, stated that the U. S. Public Health Service participated in the organization.

Health Center.—A health center was opened in Lima as an experimental center for small units to be constructed throughout the country. The center is located in the Rimac district of Lima, one of the poorer districts of the city, and was erected by the Inter-American Public Health Service in cooperation with the Peruvian Ministry of Public Health.

Physicians Threaten to Suspend Research.—According to the *Chicago Tribune* the military government of Argentina encountered new troubles in September, when a group of physicians threatened to suspend their scientific activities and a local union took sides with striking transport company employees the government had ordered back to work. The *Union Obrera* local threatened a sympathy strike to support the transport workers "when circumstances demand." The Argentina Medical Association resolved in a meeting to ask its board of directors to "suspend the association's scientific activities until constitutional normalcy is restored." The physicians' resolution said an "atmosphere of liberty, confidence, security, and tranquillity are absolutely indispensable" to investigation for scientific progress and declared "it is notorious that such conditions do not exist presently in Argentina." The action followed a similar protest by the nation's lawyers, who halted their activities and caused a virtual standstill in Argentina's courts.

Deaths

Walter Bradford Cannon * Boston, renowned physiologist, died October 1 at his summer home in Franklin, N. H., of bronchial pneumonia and leukemia.

Dr. Cannon was born in Prairie du Chien, Wis., Oct. 19, 1871. He graduated at Harvard in 1900, having been a member of the faculty in 1899 and serving successively as instructor in zoology, instructor in physiology and assistant professor. He had been George Higginson professor and head of the department of physiology since 1906, retiring in 1940 with the title emeritus.

In his book on "The Wisdom of the Body," Dr. Cannon said that his first research when a student of medicine was a study of the phenomenon of swallowing. Thus began a long career of physiologic investigation. For his distinguished achievements he was awarded the Baly Medal of the Royal College of Physicians in 1931 and the gold medal of the National Institute of Social Sciences in 1934. In 1941 he was the first recipient of the Friedenwald Medal of the American Gastro-Enterological Association in "recognition of his pioneer utilization of the x-rays in gastroenterology, and his important contributions to the mechanics of digestion, to the elucidation of the sensations of hunger and thirst, and to the development of the science and practice of gastroenterology." He had been awarded many honorary degrees and held membership and fellowship in numerous scientific groups in this country and abroad. He had delivered such prominent lectures as the Lineacre at Cambridge University, Herter, Beaumont, Caldwell, Kober, Newbold, George Brown, Welch and Jones, serving at one time as Croonian lecturer of the Royal Society and Hugglings Jackson lecturer at McGill University. From 1929 to 1930 he had been Harvard exchange professor to France and for a time in 1935 visiting professor to Peiping Union Medical School. From 1906 to 1908 he was secretary of the Section on Pathology and Physiology of the American Medical Association. In 1925, when the Association created a Council on Physical Therapy, Dr. Cannon was named one of its members. Serving as president of the Medical Research Society of the American Red Cross, France, 1917-1918, and as a lieutenant colonel in the medical corps of the U. S. Army during World War I, the medical corps of the U. S. Army during World War I, Dr. Cannon subsequently received the Decorations of the Companion of the Bath (British) and the Distinguished Service Medal for his services as director of physiologic research for the American Expeditionary Forces in France. In later years he was president of the American Association for the Advancement of Science, a member of the board of scientific directors of the Rockefeller Institute for Medical Research, vice president for America of the International League Against Epilepsy, member of an advisory committee to a council created in 1936 to administer the program of research in child neurology for the Friedsam Foundation, member of the Medical Fellowship Board of the National Research Council and, in 1943, president of a newly formed group called the American-Soviet Medical Society. In 1943 he was also elected a member of the Academy of Science of the U. S. S. R. In 1931 special ceremonies, including the unveiling of a portrait,

were held at Harvard to mark his completion of twenty-five years as professor of physiology.

Dr. Cannon always maintained an interest in medical education; early in his career he suggested the "case method" of teaching medicine. His research during World War I resulted in new concepts for the treatment of shock. Much of his work dealt with organic conditions as affected by emotion, and his investigations resulted in the established practices for controlling these disturbances. His prolific contributions to scientific literature reflect his diversified interests, his frequent articles describing movements of the stomach and intestine, internal secretions, effects of emotional excitement, surgical shock, organic stabilization, chemical mediation of nerve impulses, medical education and the defense of medical research. The books written by Dr. Cannon have been exceptional. The list includes *A Laboratory Course in Physiology*, 1910, *The Mechanical Factors of Digestion*, 1911, *Bodily Changes in Pain, Hunger, Fear and Rage*, 1915, revised edition, 1929; *Traumatic Shock*, 1923, *The Wisdom of the Body*, 1932, revised edition published in 1939, *Digestion and Health*, 1936, and *Autonomic Neuro-Effector Systems*, with Arturo Rosenblueth, in 1937. Just recently his autobiography, called "The Way of an Investigator," was published. It reflects the geniality, the philosophy and the inspiration that were the basic factors in a career that achieved greatness.

WALTER BRADFORD CANNON, M.D., 1871-1945

Bernard Isaac Comroe * Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1929; born in York, Pa., Oct. 22, 1906; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; member of the American Rheumatism Society and the Philadelphia College of Physicians; associate in medicine at his alma mater, where he was chief of the medical division of the student health service; on the faculties of the dental school and graduate school of the University of Pennsylvania; senior ward physician at the Hospital of the University of Pennsylvania, where he served an internship and a residency; during his senior year at the University of Pennsylvania, awarded the Spencer Morris prize, the alumni medal and prize and the Charles A. Oliver Memorial prize; responsible for circulating a bulletin containing news concerning the University of Pennsylvania School of Medicine and Hospital, which was sent to graduates of the school serving in the armed forces throughout the world during World War II; author of *Arthritis and Allied Conditions*; joint author of *Internal Medicine in Dental Practice*; editor of many editions of *Medical Technique Book of the Hospital of the University of Pennsylvania*; died at his home in Overbrook Hills, September 14, aged 38.

Charles Melville Bacon * Chicago; Rush Medical College, Chicago, 1914; associate in medicine at the University of Illinois College of Medicine; at one time clinical assistant in pediatrics and clinical associate in medicine at his alma mater; for many years medical director for Marshall Field & Company; served during World War I; on the staff of the Presbyterian Hospital, where he died July 12, aged 59, of coronary thrombosis.

Herbert Kitto Beauchamp * Phoenix, Ariz., Medical College of Indiana, Indianapolis, 1904; at one time one of the physicians in charge of the Territorial Asylum for the Insane; died May 24, aged 69.

James Milton Bonham, Hobart, Okla.; Kansas City (Mo.) Medical College, 1901; member of the American Medical Association; fellow of the American College of Surgeons; past president of the Rotary Club and chamber of commerce; district chairman of Procurement and Assignment of Physicians for western Oklahoma; on the staff of the General Hospital, where he died July 14, aged 75, of virus pneumonia complicated by hepatitis.

Ellsworth T. Busching, Wyoming, Ohio; Medical College of Ohio, Cincinnati, 1893; medical examiner for the Metropolitan Life Insurance Company for many years; at one time member of the board of education and board of health of Elmwood Place; died June 3, aged 77.

David W. Byrd, Norfolk, Va.; Meharry Medical College, Nashville, Tenn., 1900; one of the founders and past president of the National Medical Association; on the staff of the Norfolk Community Hospital; died July 6, aged 76, of coronary occlusion.

Eugene A. Callahan, Carlisle, Ark.; University of Arkansas School of Medicine, Little Rock, 1903; member of the American Medical Association; served as president of the Arkansas State Medical Board and of the Alumni Association of his alma mater; vice president and chairman of the board of the Citizens Bank in Carlisle; a member of the Arkansas Selective Service Board of Appeals; died May 29, aged 67.

Stark Michael Casper @ Louisville, Ky.; University of Oklahoma School of Medicine, Oklahoma City, 1923; interned at the SS Mary and Elizabeth Hospital, where he served on the staff for many years; died June 17, aged 48.

James Christopher Clarke, Los Angeles; McGill University Faculty of Medicine, Montreal, Que., Canada, 1909; served during World War I; died June 7, aged 62.

Wendell Phillips Collette, Norfolk, Va.; Howard University College of Medicine, Washington, D. C., 1929; member of the staff of the Norfolk Community Hospital; died July 16, aged 43.

Stanton Kemble Crawford, Lakewood, Ohio; University of Wooster Medical Department, Cleveland, 1888; served on the staff of the Lakewood Hospital; died July 22, aged 83, of coronary thrombosis.

James Claude Cunningham @ Little Rock, Ark.; Maryland Medical College, Baltimore, 1903; emeritus professor of obstetrics and gynecology at the University of Arkansas School of Medicine; died June 18, aged 64.

Alexander C. Dockstader, Hastings, Minn.; the Hahnemann Medical College and Hospital, Chicago, 1880; died July 16, aged 90.

Leonidas L. Duncan, Hollow Rock, Tenn.; University of Tennessee Medical Department, Nashville, 1891; member of the American Medical Association; died in the Baptist Hospital, Memphis, June 25, aged 83.

George Craig Eggleston, Amelia C. H., Va.; Medical College of Virginia, Richmond, 1893; member of the American Medical Association; died in the Stuart Circle Hospital, Richmond, June 14, aged 73.

James S. Fitzhugh, Central City, Ky.; Hospital College of Medicine, Louisville, 1902; member of the American Medical Association; formerly McLean County physician and health officer; died June 18, aged 74.

Frederick William Fletcher, Hinton, Iowa; John A. Creighton Medical College, Omaha, 1912; member of the American Medical Association; also a graduate in pharmacy; served during World War I; died in a hospital at Sioux City September 12, aged 65, of cerebral hemorrhage following an illness of over two years of endarteritis obliterans.

Alfred M. Ganaway, Nashville, Tenn.; Northwestern Medical College, St. Joseph, Mo., 1892; served during World War I; formerly associated with the Indian Service; died June 23, aged 77.

Joseph Glamkowski @ Brooklyn; Long Island College Hospital, Brooklyn, 1920; served as president of the North Brooklyn Medical Society and as treasurer of the Brooklyn Academy of Pediatrics; chief pediatrician at St. Cecilia's Hospital and on the visiting staffs of St. Catherine's and Greenpoint hospitals; died June 17, aged 50.

Louis Julius Hajdusek, Chicago; Chicago College of Medicine and Surgery, 1912; died July 30, aged 58.

William Clinton Haydon, Princeton, Ky.; Southwestern Homeopathic Medical College and Hospital, Louisville, 1905; member of the American Medical Association; died June 24, aged 64.

Charles Howard Lisle, New Hampshire, Ohio; Starling Medical College, Columbus, 1903; on the staff of the Memorial Hospital in Lima; died June 19, aged 68.

Daniel Erastus Little @ Eufaula, Okla.; Ohio Medical University, Columbus, 1903; served during World War I; county superintendent of health; died in Oklahoma City May 31, aged 66.

Otto Wilber McClusky, Chemawa, Ore.; Rush Medical College, Chicago, 1905; instrumental in building the hospital at Carrington, N. D.; served during World War I and as physician and surgeon in the Civilian Conservation Corp.; physician and surgeon for the Indian School, where he was in charge of the 50 bed hospital; died in the Deaconess Hospital, Salem, August 16, aged 71, following a cerebral hemorrhage.

James Jackson Ragan Jr., Baltimore; Johns Hopkins University School of Medicine, Baltimore, 1943; interned at the Johns Hopkins Hospital; died May 18, aged 26.

Isaac J. Sparks, Amarillo, Texas; Dallas Medical College, 1904; also a minister; past president of the Lamb-Bailey-Hockley-Cochran Counties Medical Society; died in Fort Worth June 6, aged 72.

Clarence C. Weist, Columbus, Ohio; Starling Medical College, Columbus, 1898; died in the Grant Hospital June 13, aged 67.

DIED WHILE IN MILITARY SERVICE

George Bruce Crist, Frederick, Md.; University of Maryland School of Medicine, Baltimore, 1914; member of the American Medical Association; served during World War I; entered the medical reserve corps of the U. S. Army as a captain on Dec. 24, 1923; began active duty as a major on Aug. 14, 1941; died in Fredericksburg, Va., April 8, 1944, aged 52, of coronary occlusion.

John Francis Geraghty @ Passed Assistant Surgeon, Lieutenant, U. S. Navy, Lansdowne, Pa.; Jefferson Medical College of Philadelphia, 1941; interned at the Philadelphia General Hospital; began active duty as a lieutenant (jg) in the medical corps of the U. S. Navy on July 13, 1942; promoted to lieutenant; died in Luichow Peninsula, China, June 24, aged 30, of an injury, type unknown.

George Lewis Greaser, Altoona, Pa.; Jefferson Medical College of Philadelphia, 1939; served an internship at the Charles S. Wilson Memorial Hospital in Johnson City, N. Y.; began active duty as a first lieutenant in the medical reserve corps of the U. S. Army on July 1, 1941; major, medical corps, Army of the United States; died in England June 11, 1944, aged 32, in an aircraft accident.

Alfred Labenski, Nanticoke, Pa.; Jefferson Medical College of Philadelphia, 1939; interned at the Mercy Hospital in Wilkes-Barre; entered the medical corps, Army of the United States, on May 21, 1942, as a first lieutenant; promoted to captain; died in the Walter Reed General Hospital, Washington, D. C., Aug. 19, 1943, aged 34, of adenocarcinoma of the left kidney with metastases.

Howard Bloom Mason, Freehold, N. J.; Syracuse University College of Medicine, 1925; member of the American Medical Association; fellow of the American College of Surgeons; member of the board of education of Freehold; interned at the Syracuse Memorial Hospital in Syracuse, N. Y., and the New York Post-Graduate Medical School and Hospital in New York; served as surgeon at the Fitkin Memorial Hospital in Neptune and consulting traumatic surgeon at the New Jersey State Village for Epileptics in Skillman; commissioned a lieutenant commander in the medical corps, U. S. Naval Reserve, on July 16, 1942; assigned to the U. S. Naval Hospital, Naval Operating Base in Norfolk, Va.; served in the Pacific, where he saw action at Leyte and Iwo Jima; died in the U. S. Naval Hospital in St. Albans, N. Y., July 14, aged 44, of arteriosclerotic coronary heart disease.

Howard Myers Scull, Langhorne, Pa.; University of Pennsylvania School of Medicine, Philadelphia, 1939; served an internship at the Presbyterian Hospital in Philadelphia; entered the medical reserve corps of the U. S. Army as a first lieutenant on June 14, 1939; began active duty on July 1, 1941; captain, medical corps, Army of the United States; died in the European area July 4, 1944, aged 30, in an airplane accident.

Current Medical Literature**AMERICAN**

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Periarterial Infiltration in Migraine.—According to Patzer and his associates, because of its prolonged action it was thought that eucupine (isoamylhydrocupreine) might prove useful in periarterial infiltration for the relief of migraine. The technic of infiltration is simple. The superficial temporal artery of the involved side is located external to the zygoma, and approximately 2 cc. of 0.1 per cent eucupine in 1 per cent procaine solution is injected. Often it is necessary to inject subsidiary painful points which are discovered by palpation. The results were beneficial in two ways. The majority of the patients had immediate relief, though failures were encountered, and the frequency of attacks was decreased as a rule.

Status Thymicolymphaticus.—In the past six years, according to Carr, there were seen at San Francisco coronor's office 520 cases of sudden death in children below 10 years of age. Among these were 105 children who died apparently of suffocation. Among these there were 49 cases in which death was associated with pathologic changes in the thymus and the lymphatic system. This group offers examples of death from asphyxia following tracheal compression from an enlarged thymus gland, deaths from partial obstruction by an enlarged thymus during or following anesthesia, cases showing a combination of thymic enlargement, lymphatism and anaphylaxis, and cases of adrenal insufficiency associated with thymus hyperplasia. The widespread belief that an enlarged thymus in itself will not cause asphyxia by tracheal and auricular compression and distortion can be disproved at necropsy whenever studies are done on cases of sudden death in children. However, when once accepted, status thymicolymphaticus and related terms become far too easy to use. Instead of being reserved for specific cases to which they properly apply, such diagnoses are generically used to explain many sudden deaths in children when there is no other obvious cause. Such diagnostic abuses have in the main been responsible for the disrepute of the thymic status. Orderly necropsy proceedings will reestablish the relationship of enlarged thymus glands, lymphatism, adrenal hypoplasia and such conditions, either isolated or related, as true causes of death.

Salicylate Therapy in Rheumatic Fever in Children.

Taran and Jacobs present observations on the use of massive doses of sodium salicylate in 64 children with active rheumatic disease. Their observations suggest that large doses of salicylates sufficient to raise the plasma salicylate level to from 350 to 450 micrograms per cubic centimeter produce a prompt and effective subsidence of all clinical and laboratory evidence of rheumatic activity in children with rheumatic polyarthritis. The oral route of administration is as effective as the intravenous. Experience further suggests that massive doses of salicylates in acute rheumatic carditis are equally effective in promptly suppressing all clinical and laboratory evidence of rheumatic activity. The intravenous route of administration seems to be hazardous. The usual small doses of salicylates have no therapeutic value in rheumatic carditis in children.

Poliomyelitis and Recent Tonsillectomy.—In 1943 the state of Utah experienced the most severe epidemic of poliomyelitis in its history and suffered more cases per capita of population than any other state. Because of limited facilities for contagious diseases only those patients were hospitalized who were reported by the local physician to have bulbar or respiratory involvement to the exclusion of the spinal cases.

This resulted in the admission of practically all of the clinically recognizable bulbar and respiratory cases. Of a total of 400 cases 136 were hospitalized. The frequency with which a history of recent tonsillectomy was encountered in cases of the bulbar or bulbo-spinal type was the reason that a questionnaire was sent to 334 doctors in the state requesting the following information: 1 The number of tonsillectomies on children between 3 and 16 years of age done by them in July, August and September of 1943. 2 The number of cases of polymyositis following recent tonsillectomy in these three months. 3 The age, sex and name of the child. 4 The interval between operation and the onset of symptoms. 5 The doctor's name, if he wished, or 6 The country in which he practiced. It was observed that 43 per cent of the bulbar and bulbo-spinal cases were preceded by a tonsillectomy within thirty days of the onset. The incidence of polymyositis in recently tonsillectomized children was found to be 26 times greater than in the general child population. The incidence of the bulbar and bulbo-spinal type of polymyositis was found to be sixteen times greater in recently tonsillectomized children than in the general child population.

Effectiveness of Caffeine Against Fatigue.—Huidobro and Amenbar point out that Foltz and his co-workers have demonstrated that caffeine increases in human subjects not only the capacity for muscular work in rested persons but also the speed of muscular recuperation in fatigued persons. In human experiments it is impossible to determine whether the caffeine achieves its effect through a central mechanism, through action on the neuromuscular junction or through stimulation of the muscle directly. Experiments on frogs indicate that the xanthine derivatives have a direct action on muscle itself and that they are even capable of producing an increase of muscular contraction when a muscle is stimulated indirectly through its nerve. Studies were made by the authors on cats anesthetized with dial or pentobarbital sodium or on cats which had undergone decerebration to determine the effect of caffeine injected intra-arterially in doses of 0.007 to 0.035 Gm. Observations were made on the contractions of skeletal muscles on the neuromuscular synaptic mechanism and on the superior cervical ganglion stimulated by acetylcholine. It was found that caffeine produces an increase in the tension developed by muscle which is being stimulated indirectly. Caffeine can produce tension in normal muscle as well as in denervated muscle. When denervated muscle is stimulated directly, caffeine can also increase the amplitude of contractions. Caffeine is able to augment not only the amplitude of contractions of a muscle stimulated by means of acetylcholine but also those of the contracting membrane similarly stimulated by the latter drug. The enhancing action of caffeine on the contractions of the contracting membrane stimulated by acetylcholine is due to the effect the caffeine

exerts on the ganglion. Caffeine augments the action of neostigmine. The mechanism of the action of caffeine on the neuromuscular junction consists in lowering the excitatory threshold of acetylcholine.

Etiology of Hunner Ulcer.—In his investigations on the pathologic aspects of Hunner ulcer Powell was impressed by the similarity of the microscopic picture of progressive chronic lymphatic edema and the classic histologic description of clusive ulcer. In a study of vesical lymphatics he gained the impression that the microscopic picture in a typical case of clusive ulcer is identical with a hypothetical case of chronic lymphatic edema in that area. Histologic sections of dogs' bladders with partial lymphatic obstruction were not unlike those in the majority of reported cases of clusive ulcer. The pathologic process can be better appreciated grossly at the time of operation than later when the tissues are fixed and shrunken. The history in most instances indicates a chronic process over a long period, averaging five to ten years. Probably the majority of patients with the same early history overcome their lymphatic disturbance and recover. Only the rare case with several mechanisms coming into play proceeds to the end result of Hunner ulcer.

*Fatality of Gas Gangrene in Relation to Treatment. M. G. MacFarlane.—p. 803.
Staphylococcal Pyopericardium Treated with Penicillin. H. B. Noiman and R. M. Ainsworth.—p. 806.

Effects of Protein Diet on Infective Hepatitis.—Darmady reports 61 cases of infective hepatitis, of which 32 were treated with high protein diet with superadded vitamin B complex and 29 by a classic low fat diet in which the protein was not augmented. Those on the experimental diet did not show improvement over those in the control series. This is in striking contrast to the claims made by Beattie, who has stated that it is possible to reduce the time spent in the hospital with hepatitis by as much as 37 per cent by dietetic measures alone. He further states that, roughly, the average stay in the hospital is inversely proportional to the daily intake of protein. The author cites factors which suggest that the effect of protein is maximal as a protective but not as a restorative measure and that, as protein deficiency is not found in the Royal Air Force, this may be the reason for the similarity of the two series. It is clear that no harm arises as the result of the increased protein.

Fatality Rates of Gas Gangrene.—MacFarlane says that, out of a total of 295 reports of anaerobic infections on army form I 1241 between the beginning of the campaign in Sicily and June 1944, 185 reports have been considered to be typical of cases of gas gangrene. The reduction in the death rate when antitoxin and bacteriostatic drugs were used in addition to surgical measures affords a striking testimony to the value of the combined method of treatment. However, the ancillary measures had their limitations in cases in which surgical excision was impossible. There was no significant difference in the death rate between those who received penicillin systemically and those who did not, even among cases in which a decrease might legitimately be expected if effective chemotherapy could compensate for inadequate surgical excision. This implies not that penicillin is without value in the treatment of gas gangrene but simply that its value as a specific treatment in the sense that the death rate was lower among those treated is not proved. Whether penicillin controlled the bacterial infection is another matter and one difficult to assess when several measures were often employed. It seems possible that when there is a failure of circulation through the infected area the local application of penicillin might be the more effective route. In a number of cases the immediate cause of death was renal failure rather than a fulminating toxemia, and there is a similarity between this type of case and the crush syndrome. The hypothesis that a toxic substance is absorbed from muscle damaged by trauma or ischemia is not new, but lately, with the recognition of the crush syndrome and the occurrence of massive limb wounds, it has aroused much interest. It is not unlikely that a necrotic bacterial toxin, such as *Clostridium welchii* alpha toxin, might accelerate or augment the liberation of a "muscle toxin" and thus have a potent secondary effect in addition to a direct action on a vital organ. The combined method of treatment with surgical measures, intravenous antitoxin and bacteriostatic drugs was highly effective in reducing the death rate in cases of gas gangrene of the leg or arm. The death rate in cases of gangrene of the thigh, buttock or shoulder region was approximately 40 per cent in spite of such treatment, even among those who received penicillin systemically.

Penicillin in Noma.—Pernetta and his collaborators report a case of noma in a child 3 years of age with generalized tuberculosis and with *Ascaris lumbricoides* infection. The treatment consisted in intramuscular injections of 10,000 Oxford units of penicillin every three hours and daily local injections of a solution of 5,000 Oxford units in isotonic solution of sodium chloride for three consecutive days. The total dose of penicillin administered was 300,000 Oxford units. Spread of noma was arrested after the first injection, the necrotic tissues sloughed away and the wound rapidly healed.

Genital Diphtheria Transmitted by Sexual Intercourse.—Vogelsang and Melsom report the case of a man, aged 32 who consulted one of the authors for a genital sore on the fore skin, which had a grayish white appearance and was indurated. *Treponema pallidum* could not be found and Wassermann, Kahn, Meinicke and Müller reactions were negative. Two weeks later the foreskin and penis showed considerable swelling, and phimo-sis had set in. The patient had similar sores on one finger and on the thigh. Bacteriologic examinations revealed diphtheria bacilli in all three sores. The fauces were injected and also yielded diphtheria bacilli. The man's mistress was found to have a genital sore and erosions which were free from *Treponema pallidum* but contained diphtheria bacilli. Her throat and nose showed no signs of diphtheria. It is supposed that in the man autoinoculation with diphtheria bacilli proceeded from fauces to penis and subsequently to other sites. The lesion on the penis seems to have appeared from four to five days earlier than the vulvar lesion in the woman, and it is assumed that the infection was transmitted from the man to the woman.

Book Notices

Microbial Antagonisms and Antibiotic Substances. By Selman A. Waksman, Professor of Microbiology, Rutgers University, New Brunswick, N. J. Cloth. Price, \$3.75. Pp. 350, with 35 illustrations. New York: Commonwealth Fund; London: Oxford University Press, 1945.

The application of antibiotics to the management of human disease has stimulated a tremendous interest in the subject of microbial antagonisms. It is indeed fortunate that Professor Waksman has responded to the renewed interest in this field with an authoritative and comprehensive survey of the subject. Knowledge of the antagonistic interrelationships of microbes is not recent. These phenomena have attracted the attention of soil biologists for many years. The author's original observations are well known to students in this field. His purpose in this monograph is to present a review of the antagonistic activities of micro-organisms, with emphasis on these associations as they occur in nature and their relation to human, animal and plant diseases, and to discuss the chemistry and mode of action of the known antibiotics and their application to the control of disease.

The subject matter is presented in fourteen chapters. The introductory chapters are concerned with microbial antagonisms as they occur in nature. This is a fascinating exposition of biologic processes and reveals how the very existence of man is dependent on these antagonisms. The nature of these antagonistic relationships is discussed, and then there are presented methods for isolating antagonistic micro-organisms and measuring the antibiotic action. A large number of antibiotic substances have been obtained from various sources, many of them not being clearly defined at present. This information is detailed in four chapters and includes antagonists from bacteria, actinomycetes, fungi and microscopic animal forms. It is of interest that some micro-organisms, including viruses, are capable of destroying viruses. The practical significance of this knowledge is obvious, but this aspect of the subject has been little explored. There is an excellent summary of present knowledge of the chemistry of antibiotic substances followed by a discussion of the mode of action. Though the practical application of these substances to the control of human, animal and plant diseases is presented, the information will prove to be of little immediate use to the clinician.

The text is presented in a scholarly fashion and it is unusually well documented. A bibliography of 1,016 references is appended. It is particularly gratifying to see the subject developed along historical lines. The illustrations are first rate. The volume concludes with a helpful classification of antibiotic substances and a glossary. There is a general index as well as an index of micro-organisms. This monograph will be read by many students and investigators working in this field. Precise information concerning the treatment of human disease is not available for the clinicians, and therefore the monograph cannot be recommended for this purpose. On the other hand, the well informed physician will profit by a careful reading of the book.

Essentials of Body Mechanics in Health and Disease. By Joel E. Goldthwait, M.D., F.A.C.S., LL.D., Lloyd T. Brown, M.D., F.A.C.S., Loring T. Swalm, M.D., and John G. Kuhns, M.D., F.A.C.S. With a chapter on the Heart and Circulation as Related to Body Mechanics by William J. Kerr, M.D., F.A.C.P. Fourth edition. Cloth. Price, \$5. Pp. 337, with 128 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1945.

The senior author of this standard volume is a pioneer in the teaching and practice of this important subject. The national need for physical fitness has been shown in the mobilization of the nation's strength for war. In the armed forces the aim has been to secure strength, agility and endurance. Good body mechanics is essential in obtaining and maintaining all three. The large number of rejections in selective service examinations proves the importance of the subject. Medical examiners agree that most of the defects causing rejection are preventable. Some deformities and defects of adults could have been prevented by training in good body mechanics during childhood. Many of those rejected for various physical deformities could be rehabilitated or brought to greater usefulness and efficiency by appropriate training. It is possible through training in cor-

rect body mechanics to accelerate the return of both good function and health by teaching the body to work more efficiently. The proper training for the greatest physical efficiency and the early recognition and treatment of defects which lead to disease are among the chief concerns of the physician. Life expectancy has increased greatly during the past two decades. It is the duty of the physician to keep older persons as useful as possible and free from pain. Aging is a physiologic process which cannot be prevented. However, much can be done to minimize disability, to delay the appearance of disease and to keep functional and mental capacity at a high level. In this attempt the principles of treatment outlined in this book will be found helpful. In this edition many new illustrations have been added. The chapter on disabilities of the feet has been rewritten. The entire book has been reviewed and revised.

A Synopsis of Medicine. By Sir Henry Letheby Tidy, K.B.E., M.A., M.D. Eighth edition. Cloth. Price, \$7.50. Pp. 1,215. Baltimore: William Wood & Company, 1945.

At first glance one wonders whether there is a worthwhile indication for any synopsis of medicine. However, the fact that this book has lived successfully for twenty years and is in its eighth edition seems to justify its place in the medical library. The author makes no pretense of substituting this work for a textbook but recommends it to medical students who are facing examinations, to the hurried general practitioner and to the examiner or teacher who must prepare a lecture hurriedly. This edition follows Osler's *Principles and Practice of Medicine* essentially in synopsis form. The etiology, symptoms, pathology and treatment are summarized completely and thoroughly. Since the last edition there have been many changes made, especially in therapy, mainly because of the use of the sulfonamides and penicillin. Also rewritten are many diseases in which radical changes and progress have occurred in the six years since the seventh edition was published. For the limited use that a synopsis of medicine has, this book is highly recommended.

Trichomonosis vaginalis. Por Manuel Luis Perez y Oscar Blanchard. Paper. Pp. 173, with 26 illustrations. Buenos Aires: Libreria y Editorial "El Ateneo," 1944.

Among the subjects covered in this book are the history of *Trichomonas vaginalis*, vaginitis as a clinical and pathologic entity; anatomy, physiology and physiopathology of *Trichomonas vaginalis*; methods of identification of the organism; experimental infection in both animals and human beings; clinical symptoms and signs; differentiation between vaginal trichomoniasis and intestinal and buccal types; associated pathogenic organisms; complications of *Trichomonas vaginalis* vaginitis; treatment of the condition, and extravaginal complications and genitourinary disturbances in men as the result of vaginitis. The authors have reviewed practically every article written on the subject of *Trichomonas vaginalis* vaginitis, and this, of course, includes a huge number of papers contributed by Americans. The book is written in easily understandable Spanish and it is beautifully illustrated not only in black and white but also in color in the form of drawings and photographs. The publishers have done their part magnificently because the paper is of excellent quality, the typography is clear and the illustrations have been faithfully and clearly reproduced. This monograph should be in the library of every gynecologist.

Nutritive Values of Wartime Foods (Tables Compiled for the Accessory Food Factors Committee). Medical Research Council War Memorandum No. 14. Paper. Price, 1s. Pp. 59. London: His Majesty's Stationery Office, 1945.

This pamphlet comprises a number of tables of foods grouped in the commonly used categories of cereals, meats, dairy products and so on. The nutritive values of the foods listed are given with respect to the three basic components as well as iron, calcium and vitamins A, B₁ and C. These are computed on an "edible portion" and "as purchased" basis. The figures given represent the first compilation of such figures on British foods for use in evaluating dietary data. The values represent data secured from governmental and private individuals. They have been gathered and appraised by the Committee on Accessory Food Factors.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

PENICILLIN FOR SINUSITIS

To the Editor:—What is the status of penicillin in chronic sinusitis? What of its use locally?

J. Clark Cooper, M.D., Villisca, Iowa.

ANSWER.—The value of penicillin as a local therapeutic agent in chronic sinusitis has not yet been fully determined. In general two requirements should be fulfilled in order to anticipate a favorable effect: The infection must be due to bacteria against which penicillin is effective, which are mainly staphylococci, *Streptococcus hemolyticus*, pneumococci and the anaerobic streptococci; and the penicillin solution must be brought into contact with the infected areas for a long enough period to permit a favorable action. Factors which are likely to impede or prevent a satisfactory effect of penicillin are the presence of irreversible hypertrophic changes in the mucosa creating interference with the normal mechanism of drainage and the presence of such bacterial organisms as the gram negative bacillary types. Acute exacerbations of a chronic sinusitis have responded well to parenteral administration of penicillin. Chronic suppuration which has been localized chiefly to the maxillary antrum and anterior ethmoids has sometimes responded well following removal of the pus and instillation of penicillin solution. Empyema in which the predominant organisms were of the gram negative bacillary types have also sometimes responded well to such treatment.

The results so far reported indicate that penicillin will have a definite value as a local therapeutic agent.

COUGH ASSOCIATED WITH EATING

To the Editor:—A woman aged 19 developed a severe cough two months ago, which comes on during or immediately after eating. Physical examination is negative except that she is a stammerer. Films and competent fluoroscopy examination carefully repeated are negative. A good eye, ear, nose and throat specialist finds some small local throat condition which he ascribes to postnasal drip which might be causative; however, treatment of this condition has produced no results. The pulse rate is 70; blood pressure, urine, serologic reaction, heart, diaphragm, abdomen and history are normal.

Leland H. Anderson, M.D., Aurora, Ill.

ANSWER.—The question does not state definitely whether the x-ray examination included fluoroscopy of the esophagus. Patients with cardiospasm may complain primarily of a troublesome cough after eating. Assuming that this possibility has been excluded and with no evidence of an organic connection between the esophagus and the tracheobronchial pulmonary system, the possibility of a faulty mechanism of deglutition must be considered.

The usual mechanism for production of cough on swallowing is the entrance of food into the larynx. This is normally prevented by the contracture of the thyrohyoid muscle, which raises the trachea and brings its opening under the shelter of the epiglottis and the root of the tongue. The elevation of the larynx is the important safeguard. When the larynx is fixed by disease or its movement is hindered, swallowing is difficult or impossible. Coincidentally with the upper movement of the larynx the vocal cords are approximated. A short inspiration (inspiration of swallowing) occurs at the commencement of swallowing and is followed by complete inhibition of respiration, which persists to the end of the second stage of swallowing. The fact that the patient is a stammerer may be important. Stammering is a disturbance of muscular function and coordination probably emotional in origin and thus related to the psychoneuroses. Speech employs muscle groups concerned in the elemental processes of sucking, chewing, breathing, swallowing and vomiting. Possibly under certain conditions of emotional strain incoordination of the muscles of deglutition may occur sufficient to allow particles of food to enter the larynx and thus initiate the cough reflex. Therapy would entail a thorough examination by a competent otolaryngologist and a neuropsychiatrist. The possibility of chewing more solid foods in an effort to produce a pasty bolus less likely to spill into the trachea might be considered. Perhaps the effect of eating alone might be given a trial.

INELIGIBLE BLOOD DONORS

To the Editor:—The traveling Red Cross blood bank unit has been in this village on two occasions. Following each such collection the local chairman of the Red Cross has received a list of names of donors who should not be used again. What is there in the processing of plasma that should cause the processing plant to recommend against certain persons being accepted as donors?

Edmund J. Quirk, M.D., Chelsea, Mich.

ANSWER.—The list described is not compiled by the plasma processing laboratory. It represents the persons who, in the opinion of the physician in charge of the mobile unit, should not be blood donors on account of various physical conditions, such as heart disease, high blood pressure, anemia, gastric ulcers, underweight or history of malaria. The list, simply made up as names and without reasons or diagnoses, is sent to each local chapter so that the soliciting of ineligible persons as donors for future mobile unit visits can be avoided. The only persons whom the processing laboratory recommends not to take as future donors are those whose blood is serologically positive for syphilis, but the names of these persons are not included in the list to which reference is made.

DERMATITIS AND THE MENOPAUSE

To the Editor:—During the last three years I have encountered a few cases of an identical skin condition. The affected patients are physically healthy women of a rather nervous type in the midst of the menopause, and without important vasomotor symptoms. They present an erythematous papular dermatitis with a tendency to chronicity localized on and around the ear lobules and extending into the external auditory canal. Improperly handled, patches of dermatitis madidans or crustosa appear. Itching is a most annoying factor, especially in the auditory canal. From the ear it tends to spread retroauricularly toward the scalp and preauricularly to the cheeks and neck, with occasional papules over the sternum and the limbs. Local treatments used routinely have no effect. A high dose of estrogen given intramuscularly in an empirical dose twice weekly brought about complete clearing in three to four weeks. A mild cream was used locally. Itching subsided within two or three days after the first injection. The doses that I used were 50,000 international units of estrogen (I used Progyon B) as the initial dose, with doses of 10,000 units to follow.

Charles J. Mehlmann, M.D., New York.

ANSWER.—The dermatologic condition, according to the data in the query, suggests a contact dermatitis due possibly to some cosmetic preparation or some other external agent perhaps carried by fingers. It is difficult to decide whether these cases started simply as an eczema, so called, of the ears, or whether there was a monilia infection in the beginning, or whether there was a seborrheic factor in the scalp as a starting point.

It is impossible to explain why the high doses of estrogen should effect such a change. Some women about the time of the menopause will have conditions of various organs respond favorably to additional estrogen. It would be difficult to decide which of three factors was the more important: (1) the effect of the estrogen, (2) the effect of planned treatments with a hypodermic needle, in other words, the psychotherapeutic effect, or (3) the use of a mild soothing cream externally, perhaps as a contrast to the many different, often strong agents which are sometimes used to help such conditions.

TREATMENT OF FILARIASIS

To the Editor:—I should like references to the best opinions on the treatment of patients infected with the filaria organism.

Robert D. McCradie, M.D., Oakland, Calif.

ANSWER.—There are several types of filarial organisms, the most common of which is *Wuchereria bancrofti*. This organism is responsible for practically all of the infections in the service men. The treatment of these early infections is entirely symptomatic, but because of their mildness little or nothing is needed. The main symptoms are retrograde lymphangitis, tender lymph nodes and occasional lymph edema. All are transient. There are no chemotherapeutic agents of any proved value.

WATERY CYSTS OF THE CONJUNCTIVA

To the Editor:—In the query on Watery Cysts of the Conjunctiva in The Journal, Aug. 25, 1945, page 1260, what Dr. Thompson describes conforms to the appearance of the condition called lymphectasia. Lymphectasia results from dilatation of the lymph channels of the conjunctiva. The cysts appear as small transparent beads. They cause little or no trouble. If treatment is required they may be opened or excised.

SODIUM RESTRICTION IN THE DIET FOR HYPERTENSION

ARTHUR GROLLMAN, M.D., PH.D.

T. R. HARRISON, M.D.

M. F. MASON, PH.D.

JAMES BAXTER, M.D.

JOSEPH CRAMPTON, M.D.

AND

FRANCIS REICHSMAN, M.D.

DALLAS, TEXAS

In connection with studies of experimental hypertension the effects of various types of diet on the blood pressure have been studied, including alterations in the content of vitamins, proteins, minerals and certain other dietary constituents. In the course of these investigations it was noted that diets very low in sodium content appeared to exert a hypotensive effect which was abolished by the addition of sodium chloride. The association of a low sodium content of the diet with a hypotensive response was so striking that the studies were extended to a series of patients. The results thus far obtained would appear to indicate that in certain patients this form of therapy is decidedly beneficial. The experimental basis for this work is reported elsewhere,¹ the present paper being confined to our observations on human patients only.

OBSERVATIONS ON PATIENTS

Thus far 6 subjects have been investigated while rigidly controlled in the hospital. The blood pressure was taken twice daily, at least five readings being made each time, and the results averaged. For the sake of convenience the six readings taken during each three day period have been averaged and are recorded in the accompanying charts.

The diets used in the patients were made up of foods which are naturally low in sodium content. A typical menu for a week is shown in the table. In order to provide an adequate protein intake and at the same time achieve drastic sodium restriction, it was necessary to dialyze the milk consumed by the patients. In this way it was possible to administer a 2,000 calory diet daily which contained less than 1 Gm. of sodium chloride.

In 2 of the 6 patients the blood pressure declined to essentially normal levels and promptly rose again to the pretreatment values when 20 Gm. of sodium chloride was added daily to the diet which had previously

resulted in a reduction of their blood pressures (charts 1 and 2). Subsequent cessation of the use of this added sodium chloride again resulted in a decline in blood pressure, as had been noted previously.

A third patient (chart 3) displayed a moderate decline in blood pressure, but the values did not at any time approach the normal.

Another subject (chart 4) had no decline in blood pressure despite the use of the diet for several weeks.

The fifth patient had carcinoma of the liver in addition to hypertension. This person displayed practically no change in blood pressure until a collapse reaction developed, with prompt recovery following saline administration (chart 5). This subject was the only one in whom any harmful effects of rigid sodium restriction were observed. (None of the patients reported have been followed during hot weather, and it is possible that harmful effects may occur more frequently when sweating is excessive.)

The sixth patient was moribund from uremia when the diet was begun and died within three days. No conclusions can be drawn concerning the effects of the diet in this instance.

More detailed information concerning the patients is offered in the following case abstracts:

CASE 1.—E. M. B., a Negro woman aged 37, had unilateral exophthalmos and other typical manifestations of an aneurysm of the left internal carotid artery. She was known to have had hypertension for at least three years. For fifteen years she had considerable frequency and burning on urination, and these symptoms had been only partially relieved by removal of uterine myomas eleven years previously.

On admission to the hospital the systolic blood pressure was 235 mm. of mercury and the diastolic was 130 mm. The retinal arteries displayed no abnormalities. The heart was moderately enlarged. The catheterized urine showed a faint trace of albumin, a few leukocytes and a positive culture for *Escherichia coli*. The Wassermann reaction of the blood was positive. The highest specific gravity obtained with concentration tests (Fishberg technic) was 1.023. She excreted 70 per cent of the phenolsulfonphthalein injected within two hours.

The blood pressure record is shown in chart 1. During the control period the patient displayed a striking decline in blood pressure on rest alone. After the pressure had become stabilized at about 160/105 sodium restriction was begun and the pressure then declined to normal levels, the exophthalmos disappearing. The addition of 20 Gm. per day of sodium chloride resulted in a rapid rise in blood pressure, and at this time the unilateral exophthalmos returned. She was again put on the low sodium diet, with a decline in the blood pressure to normal values. At a later date she was allowed to begin work during the day, remaining in the hospital at night. This resulted in a slight increase in blood pressure, which was now at the upper limits of normal. When a diet consisting of the regular hospital diet without added salt was substituted for the specially selected low sodium diet there was a slight increase in the blood pressure, which rose further when 5 Gm. of sodium chloride was added

Aided by grants from Mr. Joe Werthan and Mr. Alfred Starr. From the Department of Experimental Medicine of the Southwestern Medical College and the Medical Service of the Parkland Hospital, Dallas, Texas.

1. Grollman, A., and Harrison, T. R.: The Effect of Drastic Sodium Restriction on the Blood Pressure and Survival in Experimental Hypertension, to be published.

to the diet. The institution of the original sodium poor diet caused the blood pressure to decline for the third time.

CASE 2.—M. L., an obese Negro woman aged 31, was known to have had hypertension for approximately six years. Her chief symptoms consisted of occasional headaches of a migrainous type. She had had suggestive manifestations of a low grade pyelitis on two occasions in the past. No significant changes were observed in the optic fundi. The heart was at the upper limits of normal in size. The maximum specific gravity of the urine was 1.034 (Fishberg technique). The catheterized urine contained 15 to 20 white blood cells per high power field and occasional red blood cells. Culture of the urine was negative. Phenolsulfonphthalein excretion was 70 per cent in two hours.

patient then displayed a slow rise in blood pressure up to the level which existed prior to the sodium restriction. Institution of sodium restriction was again followed by a decline in blood pressure to within the upper limits of the normal range.

CASE 3.—M. K., a white woman aged 41, had attacks of acute pyelitis at ages 18 and 28. Following the first attack she had intermittent symptoms of cystitis until about two years prior to admission to the hospital. She was first found to have hypertension in 1941, at which time her blood pressure was 250/130. She had remained asymptomatic most of the time but had one attack of weakness of the left arm lasting three days and had experienced two syncopal attacks, during which the blood pressure was higher than the usual level. She had

* Included in the diet indicated, 1,400 cc. of diluted milk was administered daily.

The blood pressure is shown in chart 2. Following a well defined decline in pressure, with rest in the hospital, the pressure became stabilized at a level of approximately 160 to 170 mm. systolic and 110 diastolic. Drastic restriction of sodium in the diet resulted in a decline in pressure to a level of approximately 135 to 140/100. The administration of 20 Gm. daily of sodium chloride, all other factors being kept constant, caused a rise in blood pressure to the previous level and a subsequent decline when the sodium chloride was withdrawn. In an attempt to reduce the blood pressure from the slightly elevated level of 140/100 to strictly normal values, an even more drastic regimen of sodium restriction was instituted and ammonium chloride was administered for the purpose of increasing the excretion of base. A minimal but definite decline in blood pressure occurred, and at a later date the diet was replaced by the hospital diet without the addition of salt at the table. The

been under a great deal of emotional stress for a number of years. The chief findings on physical examination were as follows:

The retinal arteries showed considerable variation in caliber and had a silver wire appearance, but no papilledema, hemorrhage or exudate were noted. The blood pressure was 215/130, the heart slightly enlarged, and there was a presystolic gallop. The highest urinary concentration observed with the Fishberg technique was 1.022. Urine cultures were sterile. During the preliminary period of rest in the hospital the blood pressure was usually in the region of 200/120, with occasional elevations from this level during periods of emotional stress. On one occasion following receipt of a telegram containing disturbing news the pressure was found to be 260/155.

The blood pressure is shown in chart 3. Following the institution of drastic sodium restriction a slow decline in blood

pressure occurred, the values averaging about 160/100. Occasionally values as low as 150/90 were observed, which were decidedly lower than had been found at any time within the previous four years. Following several weeks in the hospital she was allowed to go home and to resume normal activity at a somewhat restricted level. This resulted in a slight increase in her blood pressure, which, however, did not return to a level as high as that observed at rest in the hospital prior to the institution of the sodium restriction.

CASE 4.—F. H., a white woman aged 43, had had convulsions during her first pregnancy twenty-five years previously and was told that she had an increase in blood pressure at that time. This subsided and she had no hypertension during her next two pregnancies. However, the hypertension recurred during her fourth pregnancy ten years before admission to the hospital. Two years later she began to have severe frontal headaches. For four years she had occasional attacks of precordial pressing pain radiating into the left arm and relieved by glyceryl trinitrate. Her father, two brothers and one son are known to have had hypertension. The patient was emotionally very unstable and showed a striking fluctuation of the blood pressure in relation to her emotional state. During the period of study she was

In addition, the patient had hypertension, which remained fairly stable during the control period at 180 to 190 systolic and 120 diastolic. There was no cardiac enlargement and the patient had no symptoms referable to his hypertension. There was 25 per cent retention of sulfobromophthalein at the end of thirty

Chart 1 (case 1).—The initial decline occurring during the first three days was the result of rest in the hospital. The further decline occurred during rigid restriction of sodium in the diet. The addition of sodium chloride, the diet remaining unchanged, caused a prompt rise in the blood pressure, which again declined when salt was omitted. Liberalization of the diet and increase in activity caused increase in the blood pressure, which again declined when drastic sodium restriction was instituted.

under considerable emotional stress because of anxiety about her son, who was in active combat with the Marines.

Physical examination revealed moderate cardiac enlargement and considerable narrowing of the retinal arteries but without papilledema, hemorrhage or exudate. The maximal urinary specific gravity obtained with concentration tests was 1.017. However, she was able to excrete 80 per cent of the injected phenolsulfonphthalein. The urine contained a moderate amount of albumin and a few granular casts, but no erythrocytes or leukocytes were observed.

The patient was given a period of six weeks of drastic sodium restriction, but no significant change in the blood pressure occurred (chart 4). At the end of this time she was given 10 Gm of sodium chloride daily in addition to that in the regular hospital diet. However, this had to be discontinued within a few days because she began to have paroxysmal nocturnal dyspnea. In this case sodium restriction was a complete failure as far as the blood pressure was concerned.

CASE 5.—W. W., a Negro man aged 36, complained of pain in the right upper quadrant and was found to have a nodular, stone-hard liver. A diagnosis of carcinoma of the liver was made and the disorder was thought to be primary, since careful studies revealed no evidence of involvement of any other organs.

Chart 2 (case 2).—Rigid restriction of sodium, which was not begun until the pressure had become stabilized as the result of rest, caused a well defined decline in the blood pressure, which rose when sodium chloride was added to the otherwise unaltered diet. Omission of the salt led to a second decline in pressure. A slight further decline apparently occurred when ammonium chloride was administered. The pressure increased when the regular hospital diet was given and again declined when the original low sodium diet was employed.

minutes. The cephalin-cholesterol flocculation test was positive. The urine contained a few white blood cells and a moderate amount of albumin. The maximum specific gravity obtained by concentration procedures was 1.033 (Fishberg technic).

The blood pressure data are shown in chart 5. During the first several weeks of drastic sodium restriction there was only a minimal decline in the systolic pressure when the patient was on the low sodium diet, and practically no response in diastolic pressure. However, after about five weeks he developed a collapse reaction, severe cramping abdominal pain and a sharp decline in blood pressure. At this time his general condition was considerably worse than it had been before and he was given 2 liters of isotonic solution of sodium chloride daily because he could not take food or drugs orally. Following the administration of sodium chloride by infusion the blood pressure returned to the previous level. He died about two weeks later, but permission for autopsy could not be obtained. In this case, unlike cases 1, 2 and 3, in which the decline in

Chart 3 (case 3).—Rigid restriction of sodium was followed by a decline of approximately 35 to 20 mm in the systolic and diastolic pressure respectively. The increase in activity when the patient was allowed to leave the hospital was attended by a rise in the blood pressure, which, however, remained below the level during the control period of rest and regular diet.

blood pressure was associated with clinical improvement, reduction in pressure was associated with deterioration of the clinical state.

CASE 6.—G. M., a white man aged 63, was admitted to the hospital in a state of advanced uremia. He was almost moribund when the low sodium diet was begun. Because of his condition a stomach tube was passed and the diet administered through

Chart 4 (case 4).—The low sodium diet was without significant effect on the blood pressure.

the tube. Within three days a sharp decline in blood pressure occurred, but the patient's clinical state continued to deteriorate and he died within seven days after the low sodium regimen was instituted. Because he was moribund when therapy was begun, no conclusion can be drawn from the drop in blood pressure which occurred, as such a decline might well have taken place spontaneously in a moribund patient.

COMMENT

The use of a "low salt" diet as a measure in the therapeutic management of patients with hypertension is not

new. It has been advocated particularly by Ambard² in France, Allen and Sherrill³ in this country and Volhard⁴ in Germany. These observers apparently believed that any beneficial effects observed were to be ascribed mainly to chloride restriction and apparently did not appreciate the peculiar significance of the sodium ion. However, the definitive value of drastic salt restriction has not been accepted generally, and this form of therapy has never been widely used. The present attitude toward salt restriction is perhaps best illustrated by the following statement from one of the world's leading students of hypertension:⁵

All in all, it does not seem demonstrated that the benefits obtained in essential hypertension by rigid salt restriction suffice to render its general use in the disease worth while. Equal results may be obtained by moderate restriction of sodium chloride. The patients should be instructed to avoid salty foods and not to add any considerable quantity of salt to the food. But there is no objection to the use of sufficient salt during the preparation of the food to render it palatable.

Moderate restriction of sodium usually fails to influence appreciably the blood pressure, and the employment of moderate rather than drastic restriction is probably the reason why this form of therapy has not been successful. Thus, the failure of McLester,⁶ of O'Hare and Walker⁷ and of Berger and Fineberg⁸

to obtain demonstrable results can probably be ascribed to the use of diets not sufficiently low in sodium content. Furthermore, the observations of Mosenthal⁹ in patients and of others in experimental animals¹⁰ that the addition of sodium chloride to the diet did not further elevate the blood pressure tended to discredit the earlier reports on the usefulness of salt restriction. Moreover, the lack of controlled observations on animals with experimental hypertension, such as are presented for the first time elsewhere,¹¹ militated against the acceptance of this form of therapy.

It is very probable that the incidental salt restriction is responsible for the results reported recently by Kempner¹¹ with the rice diet and also for the numerous responses reported to have occurred following restriction of the diet to certain fruits, vegetables, milk or periodic fasts. These results are essentially those obtainable by a more general diet equally low in sodium. In animals the addition of sufficient sodium chloride completely inhibits the hypotensive effects of a diet limited to rice, and equally striking effects are seen with potatoes, peanuts or soy beans.¹

From a practical point of view it may be necessary that salt restriction be extremely rigid if it is to be effective. This can best be accomplished by dialyzing such food as milk to remove the sodium chloride, selecting foods which are naturally low in their sodium content, and by the liberal use of flavoring agents such as pepper, lemon juice, garlic and vanilla, to overcome the insipid taste of salt free food. It is, moreover, necessary to observe the patients closely, particularly in hot weather, for symptoms of salt deprivation.

At the present time we have no method other than the therapeutic trial to determine which subjects will respond and which subjects will not respond to drastic sodium restriction. However, in some patients the declines in the blood pressure are striking, and in view of the relative ease with which this method can be applied it seems to offer, for certain patients, the most practical and effective therapeutic measure that is at present available.

Chart 5 (case 5).—During the first three weeks of the low sodium diet only a minimal change in blood pressure occurred. The administration of ammonium chloride was apparently without effect. After five weeks on the restricted diet a sharp decline in blood pressure occurred and symptoms of collapse appeared. The administration of saline solution parenterally controlled the symptoms and restored the blood pressure to the previous level.

SUMMARY

Diets rendered low in sodium content by dialysis were found to reduce decidedly the blood pressure of rats with experimental renal hypertension. That this effect was due to the low sodium content of such diets was demonstrated. It was also shown that prolonged administration of such "low sodium" diets not only was not deleterious but apparently actually prolonged the life of the experimental hypertensive animal.¹

In 6 human hypertensive patients a drastic reduction in the sodium intake, made possible by dialysis of the milk included in the diet, resulted in no decline in blood pressure in 1 subject, a reduction of the pressure to essentially normal levels in 2 and a moderate reduction in the remaining 3, 1 of whom, however, displayed acute circulatory collapse which responded promptly to sodium chloride therapy. It is suggested that such diets be utilized for a brief trial period for patients with hypertension and employed for a longer period in subjects who display a favorable response.

THE RELATIONSHIP OF THE ADRENAL
CORTEX TO HYPERTENSIONOBSERVATIONS ON THE EFFECT OF HYPOADRENAL-
ISM ON A PATIENT WITH HYPERTENSIVE
VASCULAR DISEASE

GEORGE A. PERERA, M.D.
NEW YORK

As a result of the work of Goldblatt and his associates,¹ emphasis has been placed in recent years on the role of the kidney in the pathogenesis of both experimental and essential hypertension. However, the absence of recognizable signs of impaired renal function or of significant anatomic change early in the course of hypertensive vascular disease has been advanced as an argument against renal ischemia as the primary cause of this disorder in man.²

There is considerable evidence that the adrenal cortex plays a part in the regulation of the arterial blood pressure. Hypertension may be a manifestation of certain adrenal cortical tumors, and hypotension is a frequent observation in Addison's disease even after restoration of electrolyte and water balance by appropriate therapy. Desoxycorticosterone acetate has been found capable of producing hypertension in some patients with hypoadrenalism and of raising the blood pressure in others without renal or endocrine disease.³ The administration of adrenocorticotrophic hormone has reestablished the blood pressure of hypertensive rats when depressed by hypophysectomy.⁴ And lastly, bilateral adrenalectomy interferes with the development and

maintenance of experimental renal hypertension unless cortical hormone replacement therapy is instituted.⁵

There are no reports of successful bilateral adrenalectomy in man, but the occasion has recently presented itself to follow the course of a patient with documented essential hypertension who subsequently developed hypoadrenalism. The purpose of this paper is to show the effect of adequate replacement therapy, first with desoxycorticosterone acetate⁶ and then with salt alone, on the blood pressure.

REPORT OF CASE

L. D., a white man aged 50, American born, a merchant, was first seen at the Presbyterian Hospital in 1939. There was no family history of hypertension or renal disease, and he knew of no exposure to tuberculosis. His past history, except for childhood diphtheria and uncomplicated scarlet fever at the age of 21, was noncontributory.

In 1936, three years before, he had reported to his local physician a transient episode of dyspnea and was told that his blood pressure was 160/110. During the next three years he was seen by several physicians, who found blood pressure levels consistently above 140/100. His only complaint was of moderate exertional dyspnea.

Three months before admission to the hospital, in July 1939, the patient developed progressive weakness and one episode of nausea and vomiting. Physical examination on admission revealed that the patient was well developed, was afebrile and had extensive brownish pigmentation, most pronounced over the face, neck, forearms and hands. No buccal pigmentation was noted. The blood pressure was 140/105. The retinal vessels exhibited moderate tortuosity and compression of the veins where crossed by arteries. The heart was enlarged to the left on percussion; the second aortic sound was louder than the second sound over the pulmonary area; no murmurs were heard. The remainder of the examination was within normal limits. Pertinent laboratory data included repeated normal urinalyses and a serum sodium determination of 134.1 milliequivalents per liter. The lungs were clear by x-ray, and the adrenal area showed no abnormal calcification. A 2 meter film of the heart revealed a cardiothoracic ratio of 12.9/22.9, and an electrocardiogram recorded left axis deviation and slight notching of the ventricular complexes. X-ray of the kidneys showed them to be normal in size, shape and position.

The diagnosis of Addison's disease was confirmed by salt withdrawal, with the development of increasing weakness, a drop in blood pressure to 88/66 and a serum sodium which fell to 129.8 milliequivalents per liter. The patient responded to treatment with desoxycorticosterone acetate with disappearance of all symptoms, a return of the serum sodium concentration to normal and the reappearance of hypertension.

For the next six years the patient was followed in the outpatient department at intervals rarely in excess of three months, as shown in the chart. Repeated blood pressure readings were taken in the sitting position at each visit by one of a small group of observers. Except for one hospital admission with an acute respiratory infection and fever of 104 F., during which his blood pressure fell to 110/70, he was maintained in water and electrolyte balance with 2 to 3 mg. of desoxycorticosterone and exhibited a persistent hypertension. Systolic pressures ranged from 134 to 180, diastolic values always above 90 mm. of mercury.

During this period he remained in reasonably good health but for occasional exertional dyspnea. He experienced no cardiac pain or edema, and examination of the fundi showed no pro-

6. Desoxycorticosterone acetate (Doca) was furnished through the generosity of Dr. L. A. Pike of Roche-Organon, Inc., Nutley, N. J.

gressive changes. Occasional slight albuminuria appeared after several years, and rare red cells were present in the urine during the last year of observation. Annual electrocardiograms continued to show left axis deviation and T_a became inverted. Frequent serum sodium determinations were made and were invariably normal or slightly above. These measurements were made either directly⁷ or at times—in the absence of nitrogen retention—indirectly by the summation of the carbon dioxide content and the chlorine concentration, both expressed as milliequivalents per liter, plus 10.⁸

After a preliminary serum sodium determination (137.8 milliequivalents per liter) and measurement of the plasma volume (2,840 cc. as compared to a predicted normal, based on weight, of 2,970 cc.) desoxycorticosterone was withdrawn and the patient maintained on daily oral doses of sodium chloride in excess of that in the diet. The plasma volume was determined after thirty minutes in the horizontal position with the blue dye T. 1824 and calculated from the optical density, measured with the photoelectric colorimeter, of a serum sample drawn ten minutes after injection of the dye.⁹

Effect of salt replacement on blood pressure in a hypertensive patient with Addison's disease.

After two days on 15 Gm. of enteric coated sodium chloride, mild cramps and diarrhea appeared, controlled by paregoric. He was again placed on his usual dose of 2 mg. of desoxycorticosterone for two days, then shifted to increasing doses of sodium chloride in drinking water and added to the diet for a period of one week. Throughout this time he remained ambulatory and made frequent visits to the clinic, where temperature, weight, blood pressure and other data were secured.

With no signs or symptoms of adrenal cortical insufficiency, fever, significant weight change and with no fall in serum sodium concentration below normal, the patient's blood pressure dropped to 116/80 after four days, at which time the plasma volume was again determined (2,920 cc. as compared to the original value of 2,840 cc.). At the completion of one week on sodium chloride, with blood pressures still within normal limits, desoxycorticosterone was resumed and hypertension reappeared within a few days. A subsequent electrocardiogram showed nothing to suggest that the drop in pressure had been due to a myocardial infarction.

COMMENT

The repeated finding of hypertension in this patient by multiple observers, in the absence of demonstrable renal disease and with associated slight cardiac enlargement and left axis deviation by electrocardiogram, leaves little doubt that he had essential hypertension. The subsequent development of Addison's disease was established clinically as well as chemically by a pronounced decrease in serum sodium concentration as a result of the withdrawal of salt from the diet.

Throughout a period of observation of about six years, more than three years after hypertension was first recorded, this patient maintained an elevated blood pressure even after the appearance of hypoadrenalism treated with desoxycorticosterone. The sole exceptions occurred during the initial period of adrenal cortical insufficiency and during a febrile episode due to a respiratory infection, at which times the blood pressure fell to normal or below.

Evidence is presented that the maintenance of hypertension in this patient was apparently dependent on the administration of desoxycorticosterone. Thus, when he was given sodium chloride alone, but in sufficient quantity to maintain a normal serum sodium concentration and a normal plasma volume, the hypertensive state disappeared, only to return with the readministration of desoxycorticosterone.

One can only speculate as to whether a primary mechanism is involved or whether the adrenal cortex operates through a renal or some other mechanism. The fact that desoxycorticosterone has pressor potentialities raises the question whether the abnormal liberation of certain adrenal cortical hormones may be concerned in the etiology of hypertension even though consistent anatomic change is not apparent. The sequence of events in this patient suggests that the adrenal cortex may be essential for the development or maintenance of simple hypertension in man.

CONCLUSION

1. A patient with documented hypertension, who subsequently developed hypoadrenalism, showed a persistent elevation of blood pressure while under treatment with desoxycorticosterone.
2. Replacement therapy with salt alone, even though the patient was maintained in water and electrolyte balance, resulted in a drop in blood pressure to normal limits.
3. This suggests that the adrenal cortex may be important for the development or maintenance of essential hypertension in man.

Beginnings of Intra-Abdominal Uterine Surgery.—The earlier laparotomies undertaken for the removal of ovarian cysts not infrequently revealed the presence of large fibroid masses. In the majority of instances these masses were left undisturbed, though often they were punctured and dry taps resulted. Thus uterine surgery began as a result of diagnostic error. A. A. Boinet in an article read before the Paris Academy of Medicine (1870) cited fourteen instances of laparotomies undertaken for the removal of ovarian cysts, which proved, instead, to be large fibroid uteri, and his list is not all inclusive. Boinet assigned the first diagnostic error to John Lizars (1825). It is possible that Ephraim McDowell, the father of ovariectomy, was dealing with fibroid growths in the second and fourth cases of his series, and A. B. Granville's description of his second failure strongly suggests that he was dealing with a fibroid rather than an ovarian cyst (1826). In none of the cases cited by Boinet was the fibroid growth removed.—Ricci, James V.: *One Hundred Years of Gynecology*, Philadelphia, Blakiston Company, 1945.

PERTUSSIS IMMUNIZATION PROGRAM OF THE BOSTON HEALTH DEPARTMENT

THE COMPARATIVE VALUE OF TWO DIFFERENT ANTIGENS

LEO CRAVITZ, DR.P.H.

Teaching Fellow in Public Health, Massachusetts Institute of Technology

JOHN H. CAULEY, M.D., M.P.H.

Deputy Commissioner, Division of Communicable Diseases, Boston Health
Department; Assistant Professor in Public Health and Preventive
Medicine, Boston University School of Medicine; Junior
Visiting Physician, Boston City Hospital
BOSTON

GENERAL PLAN OF THE IMMUNIZATION PROGRAM

In March 1942 the Boston Health Department instituted a pertussis immunization program in an effort to protect children against pertussis during the earlier months of their lives. All presumably susceptible infants between the ages of 6 and 12 months were eligible to receive prophylactic inoculations against pertussis at their local well baby clinic. The well baby clinics are located in the health units and substations situated in eighteen different geographic districts of the city and are accessible to all who wish to take advantage of their services.

Two different antigens, the Parke Davis Sauer vaccine and the Lederle Detoxified Pertussis Antigen, were used for immunization. The former is a killed bacterial suspension of phase I Hemophilus pertussis cultures grown on Bordet-Gengou medium containing at least 15 per cent of human (placental) blood made up to a concentration of 15 billion bacilli per cubic centimeter. The latter is a formalized sterile toxic filtrate made from the growth of selected toxic and antigenic cultures of H. pertussis in a buffered beef heart infusion containing 2 per cent peptone and 0.1 per cent soluble starch adjusted to p_H 7.8. The Boston Health Department purchased both antigens in the open market.

Approximately half of the babies were inoculated with the Sauer vaccine and the other half with the Lederle Antigen. The total dosage for each antigen was 6 cc. The intervals between the injections were three weeks, the standard dosage for the Lederle Antigen being 2 cc. for each injection, whereas Sauer's vaccine was administered in 1, 2 and 3 cc. amounts respectively. The injections were given by the health department physicians regularly in attendance at the well baby conferences and the records of the injections were diligently kept by the nursing staff. On completion of the immunization series a card giving the essential data of immunization for each child was forwarded to the Division of Child Hygiene, where it was filed as a permanent record of immunization.

GENERAL PLAN OF INVESTIGATION

At the end of the second year of the pertussis immunization program it was deemed advisable to evaluate the program and to compare the efficacy of the Lederle Antigen with that of Sauer's vaccine. Since such an evaluation could be made only through a field survey, the aid of the Nursing Division was enlisted in the collection of the data.

First, the immunization record cards for every child who had been immunized during the years 1942 and

1943 was forwarded to the medical inspector of his respective health unit, together with an adequate number of survey forms. (A sample form is shown in the accompanying questionnaire.)

SAMPLE QUESTIONNAIRE USED IN PERTUSSIS IMMUNIZATION STUDY

Name of child.....Age.....
Address.....Station.....
Type of antigen used.....Dates of inoculation: 1st.....
2d.....
3d.....

Was child exposed to whooping cough after immunization?.....
Place of exposure: In family.....
Other household.....
Indefinite.....

Brief explanation of exposure.....

Did child contract whooping cough since immunization?.....
Date of onset.....
Virulence of disease: Very mild.....
Mild.....
Moderate.....
Severe.....

If child had whooping cough, was there a physician in attendance?.....

Give number of children in same family in same general age group who have not been immunized: Number.....

Were any of these children exposed to whooping cough?.....Number.....

Did any of them develop whooping cough?.....Number.....

Signature of nurse.....

The medical inspector then instructed the clerk of each health unit to transfer the information from the record cards to the survey forms. After these data had been recorded, the survey forms were turned over to the supervising nurse in the health unit or substation. Miss Wedgewood, the director of nurses, instructed the supervisors to distribute these forms to the general nursing staff for completion. The nurses obtained the necessary information by questioning the parents, guardian or other responsible family members of the immunized children.

SIZE OF SAMPLE AND PERIOD OF OBSERVATION

Although approximately 5,000 infants were immunized during the years 1942 and 1943, only 3,006 of these children were visited between March 1 and April 21, 1944, the period of the field study. The total period of observation extended over two years, but only a small percentage of our group experienced a whole two years risk of 33,298 months, or an average of 11.1 months per child. In the Sauer injected group, 1,871 children had 19,458 months of experience, or an average of 10.4 months per child; the 1,135 Lederle injected children were at risk for 13,839 months, or an

TABLE 1.—Number of Children in Study Group and Length of Experience or Risk Following Immunization

Groups	Persons	Number of Children and Period of Observation		
		Person-Years at Risk	Months of Risk	
			Number	Average per Person
Both groups.....	3,006	2,775	33,298	11.1
Sauer.....	1,871	1,622	19,458	10.4
Lederle.....	1,135	1,153	13,840	12.7

average of 12.7 months per child. The average period of observation for the whole group was therefore 11.1 months per child. There were no children under observation for less than four months; about 8 per cent of the children were under observation for less than six months, while more than 70 per cent were under observation for twelve or more months. These facts are recorded in table 1. This table discloses that, although

the group injected with the Sauer vaccine is larger than the group injected with the Lederle Antigen, the children injected with the Lederle product have had a somewhat larger period of risk per person. We observed that more children were being immunized with Sauer's vaccine during the second year of our study, since it was the usual practice for one full time physician to use

TABLE 2.—Incidence of Pertussis in Sauer-Immunized and Lederle-Immunized Groups Based on Period at Risk

Groups	Number of Children	Person-Years	Number of Attack Cases	Annual Pertussis per 1,000
Both groups.....	3,006	2,775	40	14.4
Lederle-immunized.....	1,135	1,153	34	29.5
Sauer-immunized.....	1,871	1,622	6	3.7

Sauer's vaccine, whereas the pediatrician employed on a part time basis utilized the Lederle Antigen for immunization.

INCIDENCE OF PERTUSSIS IN BOTH GROUPS

The diagnosis of pertussis in this study was necessarily based on the clinical histories obtained and recorded by visiting nurses. We recognize, of course, the difficulties associated with diagnosis, especially when the illness is very mild. Nevertheless the possibility of overlooking cases in our study was small, since we were dealing with very young children who usually experience a typical course of illness. The ameliorative effect of immunization may, however, contribute toward the missing of some mild cases.

There were 6 cases of pertussis in the Sauer immunized group, representing a total of 1,622 person-years experience. The 34 cases in the Lederle-immunized group experienced a total of 1,153 person-years risk. In other words, there were 3.7 annual cases of pertussis per thousand in the Sauer-immunized group as compared with 29.5 annual cases of pertussis per thousand in the Lederle-immunized group. The difference of 25.8 is significant. The data relative to the incidence of pertussis are shown in table 2.

TABLE 3.—A Correlation of Exposures with Subsequent Attacks in Sauer-Immunized and Lederle-Immunized Children

Exposure	Sauer-Immunized Group			Lederle-Immunized Group			Both Groups		
	No. of Exposures	No. of Cases	Per Cent	No. of Exposures	No. of Cases	Per Cent	No. of Exposures	No. of Cases	Per Cent
Definite in own household	18	5	27.7	19	16	84.2	37	21	56.7
Definite in other household	39	0	0.0	30	13	43.3	69	13	18.8
Indefinite	8	1	12.5	10	5	50.0	18	6	33.1
Total	65	6	9.2	59	34	57.6	124	40	32.3

In order to rate the efficacy of the immunization, the nurses obtained histories of exposure sufficiently accurate to be acceptable as a basis for determining what percentage of the exposed immunized children were protected against the disease. Frequently the nurses were familiar with the circumstances of exposure as a result of their periodic house visits. This naturally aided in the accuracy of their reports. Also, since an explanation of the exposure was always given on the survey

forms, we were able to check the classification of the exposure as "definite" or "indefinite." The only exposures considered "definite" were those occurring indoors, in the child's own household or in another household where there was intimate contact with the patient during the infectious period. The "indefinite" exposures were those occurring under less intimate conditions as, for example, playing outdoors with a source patient. An analysis of the types of exposure, correlated with the subsequent attacks, is given in table 3.

SEVERITY OF ATTACKS OF PERTUSSIS

A percentage analysis of the 40 attacks of pertussis, classified in the various severity ratings, is given in table 4. It may be noted that most of the attacks were mild, the moderate and severe cases being in the minority. Thus, in the total immunized group, 65.6 per cent of the attacks were either very mild or mild, 17.1 per cent were moderate and 17.1 per cent were severe. Since there were so few cases in the Sauer-immunized group, the cases in the Lederle-immunized group influenced these figures to a large extent. Apparently, even though the Lederle-immunized children were

TABLE 4.—Severity of Pertussis Attacks in the Sauer-Immunized and Lederle-Immunized Groups

Severity Rating	Number and per Cent of Attacks					
	Sauer-Immunized		Lederle-Immunized		Both Groups	
	Number	Per Cent	Number	Per Cent	Number	Per Cent
Total attacks.....	6		34		40	
Rated attacks.....	6	100.0	29	100.0	35	100.0

Severe.....	1	16.7	4	13.5	5	14.3
Not rated.....	0		5		5	

not very well protected against the invasion of the pertussis organism, the effects of the disease were ameliorated in a majority of the cases.

INTERPRETATION OF RESULTS

Since the two immunized groups were comparable in age, size, average period of risk per child, economic status, health and geographic distribution, any conclusions based on a comparison of the results obtained in our investigation may be considered valid. It is therefore significant to note that the Sauer-immunized group had an exceedingly low attack rate as compared with the Lederle-immunized group. Obviously the "toxoid" affords less protection than the bacterial vaccine against the attack of pertussis, even though it has been shown that the majority of cases in the Lederle-immunized children were of a mild nature. The Sauer vaccine affords excellent protection for at least one to two years, the period of observation in our study.

COMPARISON OF IMMUNIZED GROUP WITH NONIMMUNIZED CONTROL GROUP

In order to obtain a control for the immunized group of children, the nurses participating in our survey listed the siblings of the children in our study who had never been immunized against pertussis. Those siblings who were in the same general age group as the immunized children were selected for the control group. The age range allowed was from six months to six years. Infor-

mation relative to exposure to pertussis and the subsequent development of the disease was recorded on the survey forms. We recognize that it was impossible to select a control group equally comparable in age and geographic distribution to the study children but, nevertheless, we did obtain a reasonably suitable group.

In general, the control group selected was smaller and was largely composed of somewhat older children.

TABLE 5.—Incidence of Pertussis in the Immunized and Control Groups Based on the Period at Risk

Groups	Number of Children	Person-Years	Number of Cases	Annual Pertussis Attack Rate per 1,000
Immunized.....	3,006	2,775	40	14.4
Sauer.....	1,871	1,622	6	3.7
Lederle.....	1,135	1,153	34	29.5
Control.....	905	3,620	298	82.3
Both groups.....	3,911	6,395	338	52.8

However, comparing the experiences of the control group with the immunized group on a person-year basis we obtained statistically significant data. A total of 905 children with an average age of 4 years and 7 months made up our control group. Since the average age at immunization of the injected children was 7.6 months, we may consider the average period of risk per child in the control group as four years. The total person-years experience was therefore 3,620, as compared with 2,775 person-year experience in the entire immunized group. We must take into consideration, however, the fact that the pertussis incidence between 1½ and 4 years of age is approximately three times the normal incidence during the first year and one-half of life. We would normally expect, therefore, that the pertussis incidence or attack rate in the control group would be about three times that in the study group.

A comparison of the annual attack rate per thousand in the study and the control groups is shown in table 5.

We may note in table 6 that the incidence in the immunized group was about one-sixth that of the control, or approximately half of the expected incidence

TABLE 6.—Correlation of Exposures with Subsequent Attacks in the Immunized and Control Groups

in a similar nonimmunized group of the same age range. However, further observation reveals that the decrease in incidence was contributed largely by the Sauer-immunized group, since the Lederle-immunized group showed an attack rate that would be expected in a nonprotected group of this age. This, therefore, is additional evidence that a bacterial vaccine is more effective than pertussis "toxoid" for prophylaxis against pertussis.

PERTUSSIS INCIDENCE IN THE IMMUNIZED AND CONTROL GROUPS CORRELATED WITH EXPOSURE

It is possible also to compare the immunized and control groups on the basis of the number of attacks occurring subsequent to exposure to pertussis. However, we must take into account the fact that the average risk per child in the control group is greater than that in the immunized group, since some children in the former group may have experienced uneventful exposures prior to the one which resulted in the attack recorded in our study. We have tabulated the data relevant to exposure for the immunized and control groups in table 6.

The tabulation shows that a greater percentage of the control children were exposed, as could be expected. The percentage of exposed control children attacked was not significantly greater than that of the exposed Lederle-immunized children when we take into account the period of risk per child in these groups. There was a sharp contrast, however, in the percentage of exposed Sauer-immunized children attacks as compared with the exposed control group. Consequently it was the Sauer-immunized children who contributed to the reduction in the proportion of the exposed immunized group attacked with pertussis.

SUMMARY

A study of 3,006 children immunized at the Well Baby Clinics of the Boston Health Department during 1942 and 1943 was made. Of these children 1,871 had been inoculated with Sauer's bacterial vaccine and were at risk for 19,458 months, or an average of 10.4 months per child; the other 1,135 children had been inoculated with the Lederle Detoxified Pertussis Antigen and had experienced 13,839 months of risk, or an average of 12.7 months per child. The average age at immunization was approximately 7 months. Susceptible non-immunized siblings of the inoculated children were selected for a control group. The control group consisted of 905 children with a total of 3,620 person-years experience, or an average period of risk of four years per child.

In the Sauer-immunized group there were 65 exposures resulting in 6 attacks of pertussis, in the Lederle-immunized group there were 59 exposures resulting in 34 attacks of pertussis and in the control group there were 360 exposures resulting in 298 attacks of pertussis. In other words, 9.2 per cent of exposed Sauer-immunized children contracted pertussis; 67.6 per cent of exposed Lederle-immunized children contracted pertussis, and 82.3 per cent of exposed, nonimmunized susceptible control children came down with pertussis. Apparently the Sauer vaccine affords excellent protection for at least one to two years, the period of observation in our study.

The severity of the pertussis attacks was rated as very mild, mild, moderate or severe. The number of attacks in the Sauer-immunized group was too small to rate for severity. Of the 34 cases occurring in the Lederle-immunized children 31.0 per cent were very mild, 34.8 per cent were mild, 20.7 per cent were moderate and 13.5 per cent were severe. It appears therefore that even though immunization with the "Detoxified Pertussis Antigen" is less effective as a prophylactic agent than a bacterial vaccine, it serves to modify the clinical course of the disease in a majority of cases.

SPONTANEOUS ABORTION

GWEN S. HUDSON, M.D.

AND

M. PIERCE RUCKER, M.D.

RICHMOND, VA.

Pregnancy may end in one of several ways: (1) death of the mother before delivery, (2) resorption of the fetus, (3) abortion, (4) premature delivery and (5) labor at term. In rare cases of missed abortion or abdominal pregnancy it may continue indefinitely, and sometimes even when the child is within the uterus it may last unduly long.

Resorption of the fetus occurs frequently in laboratory animals when deprived of either vitamin A or vitamin E. There may be other causes. No doubt it happens also in human beings and probably more frequently than we think. The following case, which came under our observation recently, is typical:

The patient, who was in the Women's Marine Corps, was 27 years old. Her family and past history were negative. She began menstruating at 12 years. The menses occurred every thirty days and lasted seven days. There was slight dysmenorrhea, no leukorrhea. She was married on Nov. 17, 1944. Her menses in December (16-22) were normal in every way. When she failed to menstruate in January she consulted the gynecologist at the Naval Dispensary Annex in Washington, who, after an examination, thought that she was pregnant. A Friedman test confirmed his suspicions, and accordingly she was discharged from the service. She consulted us on May 11, 1945. She had menstruated in February, March and April. She had an excellent appetite and was feeling fine. Examination was entirely negative; her weight was 121 pounds (55 Kg.), height 5 feet 2 inches (157 cm.), blood pressure 114/60. The vaginal mucosa was pink, and the uterus was small, firm and anteverted. The patient was astounded when told that she was no longer pregnant and insisted on a second Friedman test. This time the test was negative.

However, it is the group who give more obvious signs of the early termination of pregnancy that we wish to discuss at this time. For several years it has seemed to us that we were having more abortions than our share. Almost always we have a patient in the hospital who is threatening to abort. We realize that patients are consulting obstetricians earlier in pregnancy than ever before. Eight or ten years ago many patients who aborted early did not even consult a doctor. Now they are more interested in reproduction, and many come for preconceptional and even premarital examinations. Probably the seeming increase in the rate of abortions is not real, but the problem is a real one, especially for the previously sterile patient.

The abortion rate is difficult to determine. Taussig¹ estimated that from 600,000 to 700,000 abortions occurred each year in the United States. He arrived at this figure by calculating 1 abortion for every 2.5 confinements in urban areas, and 1 for every 5 confinements in rural areas. It is thought that his ratio is too high and that 1 abortion to every 6 confinements is more nearly correct. Wiehl and Berry² found a fairly constant proportion of abortions and stillbirths in the various hospital and clinic studies, i. e. 2.6 per cent stillbirths and 12.1 per cent abortions (spontaneous and induced). Whelpton³ in a study of the reproduc-

tive habits of white Protestant couples in Indianapolis who had been married eleven to fifteen years and who had completed the eighth grade at school, found that unintentional abortion increased fairly steadily from 6.2 per cent among women with one pregnancy to 18.8 or 21 per cent among those pregnant seven times or more.

Anatomists and embryologists, on the other hand, find a surprisingly high percentage of defective ova in early conceptuses. Rock and Hertig,⁴ for instance, in 17 human embryos obtained before the mother had time to miss a period noted that 5 were so defective that they could not have developed. In other words, 42 per cent of embryos were defective at the very beginning. If this holds good for a larger series, the foregoing estimates of the frequency of abortions are too low.

In an effort to gain some idea as to the frequency of spontaneous abortion and also to see if the group that aborted had any clinical characteristics, we have selected for study the histories of the last 1,000 pregnancies whose termination has been under our care. We recognize that there is some objection to this manner of selection, for some of the pregnancies, chiefly consultation cases, came under our observation only at the end of their pregnancy. It is quite obvious that, had the entire series been made up of such cases, the incidence of abortion would have been nil. On the other hand, some (17 to be exact) of the abortion cases were also consultation cases, which counterbalances in a measure the unfavorable selection caused by consultations late in pregnancy. An ideal group of cases for such a study as this would be composed of those which had been under observation from the premarital examination until they had passed their childbearing period. We know of no such study, and we certainly have no such series. We have checked the histories of 250 married patients who have passed the menopause. These 250 women had 596 children and 182 abortions. This is an average of 2.38 children and 0.73 abortion per mother. There was 1 abortion in every 4.28 pregnancies.

The first of the thousand consecutive cases came under our care in June 1943, and the last delivery was on May 8, 1945. There were 107 abortions. One patient died undelivered of a gas bacillus infection. A criminal abortion had been attempted on her and she rightfully belongs in the abortion group. This, by the way, was the only maternal death in the series. There was 1 other criminal abortion in the group. The patient also had a gas bacillus infection but recovered. Twelve were therapeutic abortions and 94 were spontaneous abortions. Five therapeutic abortions were done for hypertension. Four of the 5 had a history of toxic pregnancies. Two were done for hepatitis. In both, gallbladder operations had been done. Both patients were jaundiced, and both were extremely nauseated. One still had a biliary fistula. Both improved greatly after the abortion. One abortion was done on account of tuberculosis, and 1 for heart disease. One was a mental case and 1 had otosclerosis. One had diabetes and was not doing well.

The number of previous children and abortions are shown in the tables. It is evident that as the parity increased there was an increase in the percentage of abortions. This tendency is more obvious in the table for abortions. We have always entertained the idea that there was a group of patients with immature generative organs who were apt to abort with their first

4. Rock, John, cited by Dunn, p. 66

pregnancy. After that they would go through with their subsequent pregnancies without any trouble. Four hundred and eighty patients in this series were pregnant for the first time, and of these 49 aborted spontaneously. However, as only 10.2 per cent of the primigravidas aborted spontaneously as compared with 9.4 per cent of the whole series, this group does not seem to be important numerically.

In addition to the 108 abortions there were 66 threatened abortions in which some vaginal bleeding was present with or without cramps sometime during the pregnancy. In the great majority this occurred in the first trimester. The ones who were admitted to the hospital were treated by bed rest and progesterone intramuscularly. The ones who remained at home were treated with bed rest and progesterone orally. In addition, there were 2 patients with early rupture of membranes. They had a few abdominal cramps but no bleeding.

The first was a 24 year old primigravida who was due by Naegle's rule on June 17, 1945. On January 24 the waters broke and she was admitted to the hospital. The pH of the fluid that was coming from her cervix was 7.5. On February 6 she was discharged from the hospital with instructions to remain in bed. She was readmitted to the hospital April 7 in labor and delivered a 3 pound 15 ounce (1,786 Gm.) girl. The mother was discharged on April 14 and the baby several weeks later, when it weighed 5 pounds (2,268 Gm.).

TABLE 2.—Number of Previous Abortions

6	0	0	1	0.9	1	1.0
Unstated	0	0	1	0.9	1	1.0

The second patient, a 34 year old secundigravida, was due on May 26, 1944. Her membranes ruptured on January 21, following a sudden death in her family. She was treated in the hospital for ten days and then in her home and was delivered of a full term girl on May 27, 1944.

If we add these 68 to the 94 who aborted spontaneously, we have a total of 162. This gives us a therapeutic achievement in treating threatening abortion of only 43 per cent.

Uterine bleeding in early pregnancy may be due to a partial separation of the placenta or the death of the

fetus. In the latter event we are a week or ten days too late with our treatment when the bleeding begins. When we are dealing with habitual aborters, treatment should be started as early in pregnancy as possible. Quigley⁵ had excellent results in 30 cases of habitual abortion. He emphasized the importance of beginning treatment early. In this connection one should bear in mind that there is always the possibility of carrying to a viable age a deformed baby who otherwise would have perished early in pregnancy.

The average age of the aborters was 31.8 years, the extremes being 18 and 43 years. The average age of those who did not abort was 27.07, the extremes being 13 and 44 years. Marital status was unimportant. There were 64 unmarried persons in the series and, except for the 2 who had a criminal abortion performed, all went to term. Likewise, syphilis was not an etiologic factor. Two women had positive serologic reactions for syphilis. One was treated and had a premature live baby. The other was not treated, and she gave birth to a premature macerated fetus. One husband was known to have syphilis. The wife's blood was negative. Nevertheless, she was treated and she had a full term live baby.

The smoking habits of 645 patients were noted. In the full term group there were 207 who smoked and 382 who did not smoke. The 207 smoked 2,042 cigarettes a day, or an average of 9.8. Thirty-eight of 56 aborters smoked, and these smoked 419 cigarettes a day, or an average of 10.

Ninety-four of the thousand weighed more than the maximum figure of insurance weight table for their age and height. Of these, 2 were in the therapeutic abortion group and 11 were in the spontaneous abortion group. Eighty-one overweight patients went to term. Had the same proportion of obese patients obtained in all groups, there should have been 110 in the full term group. The only patient in the entire series who suffered from underweight was 1 of the 2 with hepatitis who were aborted. Eight spontaneous aborters had hypothyroidism, as shown by a low basal rate, as compared with 6 who went to full term. Unfortunately a metabolism test was not done routinely. Had a routine basal metabolic determination been done, no doubt there would have been more subclinical hypothyroidism found in both groups.

Grip or infectious upper respiratory disease was noted in 2 aborters and in 21 of those who went to term, which is an even distribution. On the other hand, 2 diabetic patients were in the spontaneous aborter group as compared with only 6 in the full term group.

From time immemorial falls have been given a prominent place among the causes of abortion. Nineteen of the patients who went to term gave a history of having fallen at some time in their pregnancy. Three of those who aborted spontaneously gave a similar history. One did not begin to bleed until twenty-one days after her fall. The second began to bleed five days after falling down the steps and aborted two days later. The third patient, who also had pelvic inflammatory disease, began to have a bloody vaginal discharge a few hours after her fall. She aborted three weeks later. Whether the fall or the pelvic inflammation was the actual cause we have no way of determining.

Of more significance, it would seem, is the history of a previous sterile period. Nine patients with such a history aborted spontaneously and 21 went to term.

5. Quigley, J. K.: *Am. J. Obst. & Gynec.* 49: 633, 1945.

Further evidence of defective germ plasm is seen in the number of deformities of the infants. One baby had clubbed feet and 1 polydactylism. Two had cleft palate. One baby had atresia of the small intestine which was confirmed at autopsy. There was 1 iniencephalus and 1 microcephalus. Two babies had spina bifida and 1 had hydrocephalus. An additional one had a combination of spina bifida and hydrocephalus. It is significant that the microcephalic and 2 of the spina bifida infants were born to mothers who threatened to abort.

Among the gynecologic conditions associated with these 1,000 pregnancies there were 23 cases of vaginitis severe enough to warrant treatment. One of these women aborted spontaneously and 22 went to term. Of more significance is pelvic inflammatory disease. There were only 3 such cases. One aborted spontaneously, and one three weeks after a fall. One went to term. Four uterine myomas were noted, and 3 of these patients went to term. The fourth had a spontaneous abortion.

Retroversion of the uterus is probably an important etiologic factor. We do not have enough antepartum examinations or examinations early in pregnancy to determine this factor with any degree of accuracy. Seven hundred and sixty-one patients had postpartum examinations. Of these 684 went to term and 77 aborted spontaneously. Of the 684 patients who were delivered at term 183, or 26.9 per cent, had a retroversion. Of the 77 patients who aborted 34, or 44.1 per cent, had a retroverted uterus.

SUMMARY

Ninety-four spontaneous abortions and 68 threatened abortions occurring in 1,000 consecutive pregnancies were studied. Treatment with bed rest and progesterone was followed by recovery in 43 per cent. However, 3 patients who were treated successfully had deformed babies (1 microcephalus and 2 spina bifidas). Falls and intercurrent infections were of no etiologic consequences in this series. Pelvic inflammatory disease was encountered only 3 times, but 2 of these patients aborted. One of the 4 patients with uterine fibroids aborted. Two of 8 diabetic patients aborted spontaneously. Overweight patients and those with low basal metabolic rates seem to be rather prone to abort. The same is true of patients who give the history of sterility. Forty-four and one-tenth per cent of the patients who aborted had retrodisplacement of the uterus on postpartum examination as compared with 26.9 per cent of those who had term deliveries.

Medical Arts Building, Richmond 19.

Reaction of Host to Virus.—The internal situation in an animal invaded by a virus which it has not previously encountered is probably more complex than is usually thought. Very little is known as to what determines cellular susceptibility to effective invasion by a virus. One can broadly regard viruses as restricted to one or other system of tissues in the body, as being epitheliotropic, pneumotropic, neurotropic, and so on. Actually these limitations are rarely absolute and can nearly always be overstepped by strains of abnormally high virulence in either natural or experimental hosts. Within a given system of tissues there are usually certain types of cell which are more susceptible than others. In the central nervous system, poliomyelitis virus selectively attacks cells of the motor system. Influenza virus in monkeys, and probably in man, attacks the bronchiolar epithelium more severely than any other part of the respiratory lining.—Burnet, Frank MacFarlane: *Virus as Organism*, Cambridge, Mass., Harvard University Press, 1945.

LEISHMANIASIS

THE CULTIVATION OF LEISHMANIA TROPICA FROM TWO AMERICAN SOLDIERS WHO HAD RETURNED TO THE UNITED STATES FROM THE NEAR EAST

ARDZROONY PACKCHANIAN, PH.D.
GALVESTON, TEXAS

Cutaneous leishmaniasis, popularly known as oriental sore, oriental boil, Delhi boil, bouton d'orient, Aleppo boil, Bagdad boil, Bagdad sore, salek, espundia, uta and chicher ulcer, is endemic in China, India, the Near East, the countries bordering the Mediterranean Sea and South America, but not a single case of endogenous leishmaniasis has been reported as yet from the United States and Canada. However, up to the present time a total of 28 exogenous cases have been reported in these regions (Dwork,¹ Strong,² Wenyon,³ Wright⁴). The 2 additional cases of cutaneous leishmaniasis contracted by returning American soldiers which are reported in his paper might presumably be the forerunners of a more serious influx as a consequence of returning military personnel and increased traffic from the regions mentioned.

The diagnosis of cutaneous leishmaniasis usually is based on the clinical appearance of the sore and on the demonstration of Leishman-Donovan bodies in the stained preparations made from scrapings of the ulcer. This procedure is not conclusive because occasionally yeastlike organisms or other extraneous substances from the lesion may be confused with Leishman-Donovan bodies, particularly if the smears are not well stained. Wenyon⁵ and I believe that undoubtedly it was the presence of yeastlike organisms in Benedek's preparations which resulted in Benedek's⁶ erroneous report of an autochthonous case of leishmaniasis in the United States in 1941. Such errors can be avoided if the diagnosis of leishmaniasis always is substantiated by cultural tests, in which the flagellated form of the parasites is unmistakably recognizable. Actually an absolute diagnosis of cutaneous leishmaniasis cannot be made unless it is verified by the demonstration of both the aflagellar and the flagellar stages of the parasites.

Although 28 cases of exogenous cutaneous leishmaniasis have been reported in the United States and Canada since the first report in 1903, the present communication is the first from the United States and Canada in which the diagnosis has been established by the cultural method (Dwork,¹ Hoare,⁷ Wright⁴).

METHODS AND MATERIALS

Case Reports.—The first patient was a white soldier who had been stationed in Iran from December 1943 until June 1944 and was admitted to an army general hospital in Texas on Feb. 8, 1945. He states

"I was in the Bacteriology and the Laboratory of Microbiology School of Medicine, Milton Pollard, Capt E R Cockerell, Lieut Houston, Texas, and my associate Dr Joy B Cross showed interest and cooperation in this work."

that about six months earlier a small red "pimple" had appeared below the right "collar bone" and was soon encircled by several similar papules. At the time the material for the culture was secured, the eruption was composed of soft, discrete and confluent, reddish brown papules, one of which presented a small pinhead-sized ulcer. The entire lesion was surrounded by a nonsuppurative, hard, inflamed, raised, marginal zone.

The second patient, a Negro soldier, was admitted to the same hospital in February 1945. He had been returned on rotation to this country a month earlier, after about three years of service in Iran. Two scaling "lumps" had been noticed on the right leg about five months preceding his admittance. Approximately two months before he was hospitalized, the lesions had ulcerated. At the time the material for the culture was obtained, the lesions measured about 8 cm. in diameter. They were ulcerated and had raised, nonindurated, non-undermined borders and rather soft bases. The floors were covered with granulation tissue and with foul smelling purulent material and crusts.

Culture Medium.—Sterile meat infusion agar (containing 1.5 to 2 per cent agar-agar) was cooled to 45 C. and about 20 per cent of defibrinated rabbit's blood was added, mixed well, poured into test tubes and allowed to solidify in a slanted position. In order to obtain a large amount of water of condensation (about 0.5 cc. per tube) the freshly prepared tubes of medium were first refrigerated for several hours and then warmed at room temperature. After incubation overnight to assure their sterility, the tubes of medium were stored in the ice box until ready for use. This simplified medium has been referred to as N. N. medium, although it is not identical with either the classic formula of N. N., which contains 50 to 66 per cent blood, or the N. N. N. medium, which contains no meat infusion but has about 33 per cent blood (Craig,⁸ Nicolle,⁹ Novy and MacNeal,¹⁰ Strong²).

Cultural Test and Method of Securing the Inoculum.—In order to avoid contamination of the cultures with bacteria and molds, the lesions were painted with tincture of iodine, and after removal of the excess of iodine with alcohol, from 1 to 2 cc. of sterile isotonic solution of sodium chloride was injected into the bordering inflamed zone closely adjacent to the ulcerous center of the lesion. (It is desirable to use a new sterile needle and syringe for each injection and to introduce the solution into different areas of the bordering inflamed margin.) Immediately thereafter a few drops of fluid were obtained by aspiration and each sample of the aspirated fluid was inoculated into separate tubes of the N. N. medium. The inoculated tubes were rubber capped and kept at room temperature (about 25 C.) for about two weeks before they were examined for flagellates.

No positive culture of the flagellates was expected from the circulating blood of these patients. However, about 10 cc. of venous blood was withdrawn and defibrinated. About 0.5 cc. of this blood was inoculated into each of several tubes of N. N. medium; then these tubes were rubber-capped and incubated at room temperature.

Staining the Parasites.—Smears made from cultures showing a positive growth of flagellates were fixed with absolute methyl alcohol and stained by MacNeal's tetrachrome or a combination of the Wright-Giemsa

methods. The smears from the scrapings of the ulcer from the first patient were stained at the Eighth Service Command Laboratory with the combination Wright-Giemsa technic.

EXPERIMENTAL DATA

Slants of blood agar medium which were inoculated with the aspirated material from both patients were examined microscopically after seventeen days of incubation and were found swarming with flagellates, as may be seen from the table. The flagellates were leptomonad in form and were actively motile; both large and small rosettes were seen frequently. Smears stained with MacNeal's tetrachrome or with the Leishman or Wright-Giemsa stains showed a deeply colored, large, more or less centrally located nucleus and a more deeply colored, anteriorly located blepharoplast. A long flagellum extended from the anterior end of the parasite, and there was no evidence of an undulating membrane.

Much morphologic variation was noted in specimens from two to twenty day old cultures. Long forms, spindle shaped forms, large subspherical shapes and

Cultivation of Leishmania Donovanii and Leishmania Tropica from Exogenous Cases of Leishmaniasis

Exogenous Cases of leishmaniasis in the United States	Demonstration of Leishman-Donovan Bodies in Smears			Cultural Tests		
	Circulating Blood	Bone Marrow	Ulcer	Circulating Blood	Bone Marrow	Ulcer
Case 1 Kala-azar (visceral leishmaniasis).....	+	+	..	After 21 days	After 7 days	..
Case 2 Kala-azar (visceral leishmaniasis).....	0	+	..	+	+	..
Case 3 Oriental sore (cutaneous leishmaniasis).....	0	Not performed	+	0	Not performed	+
Case 4 Oriental sore (cutaneous leishmaniasis).....	0	Not performed	+	0	Not performed	+

large round forms often were observed, frequently appearing in dividing stages. Small, round, interkinetic forms were also found. The blepharoplast stained a deep bluish purple. The nucleus appeared a deep reddish purple and was not homogeneous in character. The cytoplasm was finally granular but often contained fairly large, strongly basophilic granules. The cytoplasm of some flagellates was vacuolated. The flagellum was usually about one and a half times the body length, which at times was traced in the cytoplasm up to the blepharoplast.

Cultural tests of venous blood, obtained from both patients, were examined on the fifteenth and forty-fourth days of incubation and all were found negative for flagellates.

The smears which were made from the scrapings from the first patient and stained with combination Wright-Giemsa methods revealed a few parasites suggesting Leishman-Donovan bodies. No smears were made from the lesion of the second patient. However, after obtaining positive culture of *Leishmania tropica* from the sore, the Eighth Service Command Laboratory had checked the ulcer and found Leishman-Donovan-like bodies in the scrapings from the ulcer.

8. Craig, C. F.: Laboratory Diagnosis of Protozoan Diseases, Philadelphia, Lea & Febiger, 1942.

9. Nicolle, C.: Culture du parasite du bouton d'orient, Compt. rend. Acad. d. sc. 146: 842, 1908.

10. Novy, F. G., and MacNeal, W. J.: On the Cultivation of Trypanosoma Brucei, J. Infect. Dis. 1: 1, 1904.

The strains of the flagellates, which were obtained from both patients on blood agar slants (N. N. medium), were subcultured at varying intervals and are still alive. These flagellates can neither morphologically nor culturally be distinguished from the other strains and the accepted descriptions of *Leishmania tropica*. Incidentally, the strains of *Leishmania tropica* which were isolated from these patients were found also to be identical, morphologically and culturally, with the strains of *Leishmania donovani* which I had recently cultured in California from 2 exogenous cases of visceral leishmaniasis (Munter and Packchanian¹¹).¹²

CLINICAL ASPECTS AND EPIDEMIOLOGY

(a) *Clinical Findings and Treatment.*—The incubation period is usually long and variable; the earliest lesion is usually a small papule, similar to that made by the bite of an insect. Later it develops into an ulcer, which may reach from 4 to as much as 8 cm. in diameter. A dark crust which exudes sticky fluid forms over the lesion. The raised, rimlike edge of the ulcer is not undermined and may be relatively smooth or ragged. If the crust over the center is removed, bleeding usually occurs freely and exposes a moist, superficial ulcer. The ulcers never occur on the palms, soles of the feet or the hairy scalp but are commonly found on the exposed portions of the body. Lesions may be either single or multiple. The Wassermann test is negative, and the formol-gel and serum water tests used for visceral leishmaniasis are negative. The disease as it is found in the Old World is ordinarily self limited and heals within six to twelve months with or without medical care. The sore leaves a deep, button-like depressed scar. Permanent immunity is apparently established after one infection.

In South America cutaneous leishmaniasis, which follows a similar course but often also attacks the mucous membrane, is more severe and if untreated may last several years (Chandler,¹³ Strong,² Wright⁴).

Cutaneous leishmaniasis may easily be confused with yaws, leprosy, syphilis (bejel), blastomycosis, facial lupus or cutaneous tuberculosis (Chandler,¹³ Strong,² Wenyon⁵).

If the ulcer occurs singly and is not very extensive, local treatment with an ointment containing 2 per cent of antimony and potassium tartrate or local injections of 2 to 3 cc. of a 1 per cent solution of berberine sulfate have therapeutic value. The pentavalent antimony compounds also can be injected around the ulcer. In more severe cases, however, particularly when the lesions are multiple, intravenous injections in step-up doses of pentavalent antimony preparations, such as neostibosan, solustibosan, ureastibamine (urea and stibamine) or neostam, are necessary to produce curative results (Chandler,¹³ Strong,² Wenyon⁵).¹⁴

(b) *Reservoir Hosts and Transmission.*—It is claimed that dogs may serve as a reservoir and that the disease is transmitted interchangeably between men, dogs and men and dogs chiefly by various species of sand flies (*Phlebotomus*) (Chandler,¹³ Strong,² Wenyon⁵). It is suspected that some species of lizards

may also serve as a reservoir and that mechanical transfer of the disease may take place by means of personal contact or by house flies (Chandler,¹³ Strong,² Wenyon⁵).

(c) *Geographic Distribution of Cutaneous Leishmaniasis.*—The disease is endemic in many tropical and subtropical countries in both the Western and Eastern hemispheres (Chandler,¹³ Strong²). It is found most commonly in the Mediterranean littoral and adjacent territories, as Asia Minor, Syria and Palestine. In Africa it occurs in Morocco, Tunis, Algeria, the Sahara, Egypt, the Sudan, Abyssinia, the French Congo, the district of Lake Chad and Nigeria. In India, important centers of infection are Delhi, Lahore and Multan.

In Europe the disease is endemic in the Mediterranean Islands of Sicily, Cyprus, Crete and Sardinia and has been recently introduced by returning soldiers or immigrants into southern France, Italy, Spain and Greece.

In the Western Hemisphere leishmaniasis occurs commonly in Brazil, Peru, Guiana and Paraguay. So far, cases have been reported from Mexico and from every country of South and Central America except Chile and Patagonia (Chandler,¹³ Strong²).¹⁵

In the areas where oriental sore occurs most frequently, nearly every individual has had cutaneous leishmaniasis and practically every person in such localities (as Bagdad and Haleb) has facial scars from this disease.

Obviously, cutaneous leishmaniasis is endemic and widespread in many parts of the world. Whether or not any considerable number of the United States troops who have been stationed in these regions will contract cutaneous leishmaniasis and manifest symptoms after their return to this country remains to be investigated. Since the incubation period of leishmaniasis is at times very long and since no lesions are visible during this stage, the probability of unrecognized cases entering the United States is strong (Chandler,¹³ Strong,² Wenyon⁵). The fact that there have been already 2 cases of cutaneous leishmaniasis in returned soldiers and that 499 proved cases of leishmaniasis have been recently diagnosed in the American armed forces in the Middle East (Ball¹⁶) indicates that such a possibility cannot be ignored.

In the early part of 1939 6 cases of exogenous cutaneous leishmaniasis were called to my attention by Dr. D. A. Berberian¹⁷ of the University of Beirut. These patients, medical students from the United States, had acquired the infection while in the Near East and were under treatment in New York City and Texas. Another unpublished case of exogenous, cutaneous leishmaniasis also was called to my attention during 1941. This was in a student from Delhi, East India, who was attending the Colorado School of Mines. He entered the United States approximately six months before the diagnosis was made (February 1941) by Dr. John Ambler and verified by Dr. E. R. Mudge¹⁷ of the University of Colorado School of Medicine.

Additional exogenous cases of both cutaneous and visceral leishmaniasis have been reported by other investigators (Dwork,¹ Munter and Packchanian¹¹). These reports, together with the present communi-

cation, indicate that the incidence of this disease is sporadic from coast to coast.

The fact that we have occasional exogenous cases of leishmaniasis which have been diagnosed by specialists in the United States suggests that similar unrecognized cases may occur from time to time and that it is increasingly important that clinicians and health officers be on the alert for exogenous leishmaniasis.

COMMENT

For an absolute diagnosis of cutaneous leishmaniasis it is essential (a) to demonstrate the aflagellar forms, Leishman-Donovan bodies, in smears that are made from the scrapings from the lesion and (b) to culture the flagellated forms of the parasite on suitable medium (infective material for the inoculation of culture medium may be secured from biopsy, from scrapings from the margins of the ulcer or from aspirated material from the inflamed zone surrounding the ulcer). A diagnosis based only on the demonstration of Leishman-Donovan bodies is insufficient, because occasionally yeastlike micro-organisms or other extraneous materials are found in smears and are confused with Leishman-Donovan bodies. This is particularly true if the smears are not well stained. During the fall of 1941, when I was at the National Institute of Health, I found no proof when I examined the original preparations on which Benedek⁶ based his diagnosis of autochthonous leishmaniasis. At about the same time Wenyon⁷ independently reached the same conclusion.

On the other hand, when suitable culture medium is inoculated with material containing aflagellar forms of *L. tropica* and incubated at room temperature for about ten days, a luxuriant growth of readily recognizable flagellates is obtained. The flagellates are leptomonad in form, are actively motile and colonize on the slanted portion of the blood agar.

In general, an absolute diagnosis of visceral leishmaniasis is dependent on the same factors as is cutaneous leishmaniasis. In the latter, smears and cultures are secured from the ulcer and the surrounding inflamed areas. In the former, smears and cultures are obtained from the bone marrow, the liver, the spleen or the circulating blood.

The cultural method is an important aid for the diagnosis of leishmaniasis and should be utilized always, even though it may take from one to three weeks before positive laboratory findings can be available. Positive cultures never have been obtained from the peripheral blood of patients with the cutaneous leishmaniasis (oriental sore), but cultures of flagellates may be secured easily from peripheral blood of patients suffering with visceral leishmaniasis (kala-azar) (Craig,⁸ Munter and Packchianian¹¹).

During the present study, positive cultures of flagellates were observed seventeen days after N. N. medium was inoculated with infective material; however, it is possible to find growth on this medium as early as ten days. If no growth is found by the end of thirty days the culture may be considered negative. When it is desired to maintain strains of *Leishmania tropica* in the laboratory, subcultures should be made at intervals of two or three weeks. In my experience two months old cultures of *Leishmania tropica* which were grown on N. N. medium produced subcultures rarely, and four months old cultures gave entirely negative results; however, biweekly or monthly transplants gave 100 per cent positive subcultures (Packchianian¹⁸).

SUMMARY

Positive cultures of *Leishmania tropica* were obtained from ulcers of one white and one colored American soldier who had recently returned from the Near East and had been hospitalized in Texas.

The cultivation of *L. tropica* and *L. donovani* in vitro is essential before an absolute diagnosis of leishmaniasis is made.

Ordinary blood agar slants, containing 15 to 30 per cent of defibrinated rabbit blood and an ample amount of water of condensation, produced excellent growth of the flagellates. The flagellates were subcultured at intervals of two to three weeks. They grew luxuriantly and colonized on the blood agar slants (simplified N. N. medium).

The report of cases of exogenous leishmaniasis in the American soldiers in the United States within the last year is an indication both of the expected increase in the incidence of these diseases and of the necessity that physicians and public health officials should use vigilance in the recognition of leishmaniasis and should increase their precautions against the establishment of this disease in the United States.

TRANSVERSE MYELOPATHY FOLLOWING RECOVERY FROM PNEUMOCOCCIC MENINGITIS

TREATED WITH PENICILLIN INTRATHECALLY

REPORT OF CASE, WITH A NOTE ON CURRENT METHODS OF THERAPY

SHEPPARD SIEGAL, M.D.

NEW YORK

Widespread use of penicillin has aroused interest in the management of acute bacterial meningitis. Perhaps the most fatal type has been pneumococcal meningitis, but recent reports have offered hope that at long last we possess a potent weapon against this disease. The case herein reported illustrates the occurrence of an unusual complication, transverse myelopathy, in the course of recovery from acute bacterial meningitis. This sequel is of particular current interest because of the recent report by Sweet and his co-workers¹ of severe though reversible spinal cord or nerve root damage following recovery from pneumococcal meningitis treated with penicillin intrathecally.

REPORT OF CASE

A woman aged 66, admitted to the hospital in a state of restless stupor, had awakened that morning at 8, according to her physician, complaining of pain in and behind her left ear. When he saw her one hour later he had to irrigate the external canal in order to obtain a view of the tympanic membrane, which appeared only slightly reddened. Four hours later the patient became nauseated and vomited. She became rapidly drowsier and soon lapsed into a stupor from which she could not be aroused. There was a progressive rise in temperature, which had reached 103 F. by evening.

On admission, the night of Oct. 15, 1944, the patient was thrashing about in bed, unable to cooperate in the examination. Her temperature was 103.4 F., pulse rate 84, respiratory rate 30. The blood pressure was 126/80. A stiff neck and positive Kernig's sign were present. There were a few medium rales over the right lower lobe. With the aid of restraints a lumbar

puncture was readily performed and cloudy fluid obtained. Direct smear showed many polymorphonuclears and innumerable gram-positive, slightly lanceolate diplococci. A second spinal tap was performed and 10,000 units of penicillin in 10 cc. of sterile isotonic solution of sodium chloride was introduced into the subarachnoid space. In addition intramuscular penicillin was ordered, 10,000 units every three hours. Not long afterward continuous intravenous instillation was started with the addition of sodium sulfadiazine, 6 Gm. at first and 1 Gm. every four hours thereafter.

The next day extreme restlessness was present necessitating much sedation, the most effective sedative being paraldehyde intravenously. Lumbar punctures were performed twice daily. Laboratory examination shortly after admission revealed spinal fluid 1,740 cells, 90 per cent polymorphonuclears. Direct typing showed pneumococcus type XIX. Blood culture on the day after admission was sterile. Blood count revealed hemoglobin 73 per cent, red blood cells 4,100,000, white blood cells 33,300, with polymorphonuclears 87 per cent (nonsegmented forms 36), lymphocytes 10, myelocytes 1, monocytes 2. Pronounced toxic granulation of polymorphonuclears was present. Urine examination was negative.

The consulting neurologist found no focal signs and recommended combined penicillin and sulfonamide therapy. The ear, nose and throat consultant described the left drum membrane as dusky with landmarks present, and the light reflex present

noted. The patient complained of pains in both legs. For the following five days the patient's temperature remained normal. On October 28 x-rays of the mastoids were taken and found to show but slight haziness on the left. X-rays of the paranasal sinuses showed moderate clouding of the ethmoids but were otherwise negative. In the absence of all clinical symptoms and signs no further ear, nose and throat investigation or treatment was thought necessary.

In view of the favorable course, the problem of when to stop treatment was paramount during the second week. Intraspinal penicillin was decreased to 20,000 units daily, intramuscular penicillin to 15,000 units every three hours. Sulfadiazine was likewise continued. Treatment was persisted in because of the continued low spinal fluid sugar and despite the absence of organisms. Not until the fourteenth day did this reach and remain above 40 per hundred cubic centimeters.

On October 31, the sixteenth day after onset, there was a temperature rise to 101.8 F. and the patient complained of weakness in the left leg. The next day complete flaccid paralysis of both lower extremities was present. The deep reflexes in both lower legs were gone and bilateral Babinski was present. Loss of all sensation from the tenth thoracic segment down was observed. Bladder function, which had returned five days previously, again lapsed, the patient being in retention. The lumbar puncture at this time revealed slightly turbid, yellowish fluid containing 600 cells, without any evidence of block by manometric study. The diagnosis of transverse myelopathy was made and all therapy stopped.

The neurosurgical consultant did not think the spinal cord lesion remediable by surgery and he opposed exploration. X-rays of the dorsal spine were negative. Manometric studies repeated at intervals showed persistent absence of block. The spinal fluid count fell to 50, then to 6 cells.

During the following four months the patient's flaccid paraplegia has given place to a spastic paraplegia in flexion. Only a slight degree of motor power is present in the lower extremities, the patient being absolutely bedridden. There has been some return in sensation, particularly to pain. Bladder retention has given way to incontinence. Urinary tract infection is under control with repeated courses of sulfadiazine in small dosage. The prognosis as to further return of function appears very poor indeed.

COMMENT

Transverse myelopathy, whether due to true myelitis or to myelomalacia on a toxic or vascular basis, is distinctly uncommon in the course of acute bacterial meningitis. Thus it is barely mentioned in discussions of the sequelae of meningococcal meningitis.² Occasional instances of paraplegia marring recovery from meningococcal meningitis were observed in the pre-sulfonamide era.³ Intraspinal therapy with serum or dye was usual at that time, so that the complication could be ascribed either to the disease or to the therapy employed.

Pneumococcal meningitis has until recently been so uniformly fatal that little attention needed to be paid to its possible sequelae. However, vascular involvement by the intense inflammatory process is a recognized part of the pathology and might explain certain of the complications of this disease, including transverse myelopathy. An analogous instance has been reported in the course of *Streptococcus hemolyticus* meningitis.⁴ In that case paraplegia occurred although no intrathecal treatment was administered. Autopsy revealed a severe spinal meningitis causing compression of blood

Clinical course.

but interrupted. There were no canal wall changes, no clinical signs of mastoiditis and no indication for surgical intervention.

In the two days following the patient's condition steadily worsened. Stupor gave way to coma, which deepened hourly. All reflexes disappeared. There was no longer any reaction to painful stimuli. The respiratory rate increased to 50 per minute. Throughout the fourth day Cheyne-Stokes breathing alternated with a stertorous tachypnea. The temperature varied between 101 and 103.8 F. The spinal fluid cell count reached 8,850, but on smear only two pair of intracellular diplococci could be seen. Grossly the spinal fluid was very turbid and distinctly blood tinged, and it flowed freely. The concentration of blood sulfadiazine was 22.8 mg. per hundred cubic centimeters. Because of the serious clinical condition of the patient the daily intrathecal penicillin dosage was raised to 40,000 units and intramuscular penicillin to 20,000 units every three hours.

Definite clinical improvement was noted on the fifth and sixth days of the disease. The coma lightened and slight signs of restlessness appeared. On the evening of the latter day the patient's face began to take on its normal expression, ocular movements were observed and the following morning she asked for food. The spinal fluid was sterile and showed a drop in cell count but contained less than 10 mg. of glucose per hundred cubic centimeters. Residual neurologic findings noted at this time were ptosis of the right upper lid and unequal fixed pupils. Reflexes in the lower extremities were still somewhat depressed but there were no pathologic reflexes. The temperature fell to 100 F. Two days later there was another rise to 102.2 F. and the deep reflexes were found hyperactive, with slight right ankle clonus. Equivocal Babinski reflexes were

vessels with resulting thrombosis of the anterior spinal artery. However, in the present case the active meningitis had apparently subsided before the paraplegia supervened. Nonetheless it is possible that, even when the acute inflammatory process is over, residual vascular damage may cause a complication of this type. The myelopathy encountered in this case may thus be one of the late, natural sequelae of severe pneumococcal meningitis, which are only now becoming manifest as we establish partial control over the disease by means of chemotherapy.

The recently published experience of Sweet and his co-workers prompts further discussion as to the possible relation of this form of spinal cord damage to the intraspinal therapy with sodium penicillin. The cause of the unusual parenchymatous damage which they observed could not be definitely assigned, but the intraspinal penicillin was suspected to the degree that a warning was sounded against too vigorous treatment of this kind. In 2 of their 7 cases in which recovery occurred a neurogenic bladder with overflow incontinence was observed more than two weeks after the onset of the disease. In 1 case paraplegia occurred from which almost full recovery occurred, though only after an interval of three months. These 2 patients, both adults, received intensive intrathecal treatment for a week or more, the daily dose being 80,000 units in 1 instance and 40,000 units in the other. In an earlier report, Waring and Smith⁵ employed combined penicillin and sulfonamide therapy in 12 cases and observed the occurrence of optic atrophy, with total blindness as a permanent sequela in 1 case. In this patient, a 2 month old infant, treatment was started on the second day with an initial dose of 20,000 units intraspinally, which produced rapid sterilization of the meninges. In their discussion they state that "this occurrence may bear no relationship to the intrathecal dose of penicillin but it should give us pause before injecting unnecessarily large doses of penicillin into the spinal canal."

The Waring and Smith series includes 10 other patients who recovered without incident and who received no more than 10,000 units of intraspinal penicillin twice daily. For younger patients the dose at each injection did not exceed 5,000 units. In another small series reported by Harford and his associates⁶ there were 8 uncomplicated recoveries among 9 cases. Similarly low dosage levels of intrathecal penicillin were employed. The observations in these two groups of cases suggest that 10,000 units once a day is often adequate to sterilize the meninges. If necessary this dose may be given twice daily. Emphasis should be laid on the daily spinal fluid smear and culture for evaluating the results of therapy and as a guide to further dosage. Clinical observation alone may be faulty in that improvement may not be noticeable even when the spinal fluid has become sterile. Under such circumstances it is doubtful whether the employment of larger doses of intraspinal penicillin serves any useful purpose, and it may invite the possibility of severe, even irreversible central nervous system damage. As early termination of intraspinal treatment as possible is also desirable. In some instances of pneumococcal meningitis an active feeding focus may well prevent permanent recovery no matter how long treatment is continued. Relapse of meningitis should suggest the

need for surgical eradication of such a focus as well as the need for continuance of chemotherapy.⁷

Intraspinal treatment of meningitis, so long an accepted technique, had begun to fall into disrepute before oral sulfonamides rendered it obsolete. Hoyne⁸ successfully treated 40 cases of meningococcal meningitis with intravenous antitoxin alone. Meningeal reactions had been observed to the intraspinal administration of serum or air, and Wechsler⁹ relegated lumbar puncture in meningitis to the status of a diagnostic technique. Further illustration of the occasional serious complication of usually harmless intraspinal treatment is afforded by the occurrence of severe, even fatal, toxic myelopathy following spinal anesthesia.¹⁰ In the present case the concentration of penicillin solution for intraspinal use was not more than 1,000 units per cubic centimeter. Yet the fundamental observations of Rammelkamp and Keefer had shown that even with this dilution pleocytosis of considerable degree is a usual response.¹¹ It has been suggested that employment of the alkaline sodium salt of penicillin may be particularly responsible for this degree of meningeal irritation.¹² One may recall the disastrous reactions, including myelopathy, which followed the intrathecal administration of sodium sulfapyridine for meningitis in the early days of sulfonamide therapy.¹³

There exists some difference of opinion at present as to whether penicillin given intramuscularly or intravenously reaches the spinal fluid in effective concentration for the treatment of meningitis¹⁴ although it is an accepted fact that it does not reach the normal spinal fluid in significant amounts. That this dispute may be academic is strongly suggested by the experience of Price and Hodges.¹⁵ They report the successful treatment of bacterial meningitis, including 2 cases of the pneumococcal variety, with penicillin given only parathecally. It is probable that there has been too much emphasis on the need for administering penicillin intrathecally just as there was in an earlier day on the use of intraspinal serum in meningococcal meningitis. The current controversy concerning spinal fluid levels of penicillin recalls the doubts expressed as to the probable efficacy of sulfadiazine in meningitis. The relatively low spinal fluid concentration of this drug has been found to bear no relationship to its therapeutic value. Indeed, Price and Hodges question the entire rationale of intraspinal treatment: "It is uncertain, however, whether or not the presence of penicillin in the spinal fluid is actually necessary to control infection. If the infection involves the meningeal membranes primarily it would seem that penicillin given intravenously reaches the involved tissues through the blood supply, as it does elsewhere in the body."

The most effective and the safest method for the employment of penicillin in the treatment of pneumo-

coccic meningitis is thus still an open question. Conservatively it is probably still desirable to use it intrathecally for the first few days of the disease. But this should be in limited amount, not more than 10,000 units in 10 cc. of isotonic solution of sodium chloride at each injection. On the other hand, greater emphasis should be placed on the use of larger doses of intramuscular penicillin, which should be continued after intraspinal treatment is over. Present experience suggests that the addition of the sulfonamides may increase the effectiveness of therapy.

SUMMARY

A woman aged 66 recovered from a fulminating pneumococcus type XIX meningitis. Therapy consisted of penicillin administered both intrathecally and intramuscularly. Sulfadiazine also was given. Paraplegia, bladder paralysis and sensory loss below the tenth thoracic segment, indicative of transverse myelopathy, supervened several days after apparent subsidence of the meningitis.

This serious and apparently permanent complication may be regarded as a natural although rare sequela of the disease. Or it may be due to intensive intraspinal penicillin therapy. In view of the latter possibility it is urged that greater emphasis be placed on the employment of large doses of penicillin by the intramuscular route. Intrathecal administration might well be limited to the first few days of therapy and the dose per injection to 10,000 units.

Clinical Notes, Suggestions and New Instruments

BILATERAL OPTIC ATROPHY AS A SEQUELA TO THROMBOCYTOPENIC PURPURA

PAUL V. CARELLI, M.D., AND JOSEPH P. CANGILOSI, M.D.,
CHICAGO

Bilateral optic atrophy is rarely observed as a sequela in patients suffering from thrombocytopenic purpura.

A recent review of the literature by Watkins, Wagener and Brown¹ tends to show the rather infrequent observance of "choked disk" in purpura hemorrhagica, but optic nerve atrophy was not noted in these cases.

Michail² reported 1 case of bilateral optic atrophy as following purpura hemorrhagica, in which irradiation of the spleen caused a disappearance of the petechiae but the eye condition did not improve. He also cites a case reported by Narog and another by Schall in which hemorrhages into the retina were present.

Several cases of intracranial hemorrhage following purpura hemorrhagica have been reported at necropsy and reviewed by Alpers and Duane.³ These cases involve cerebral, ventricular and meningeal hemorrhages which vary in size from small pin-head hemorrhages to lentil-size lesions.

Choking of the disk may reach quite a high degree, as in the case of Herzfeld and Rohrschneider,⁴ in which there was choking of 4 and 5 diopters with no localizing signs. This choking later receded in the course of two months. The same was true

in the case reported by Alpers and Duane, in which the choking disappeared completely.

In 1916 Kaznelson⁵ recommended splenectomy for the cure of thrombocytopenic purpura. In addition Whipple⁶ reported a series of cases in which a high mortality (87 per cent) resulted because the spleen was removed during the acute stage of the disease. In his report he strongly advised against splenectomy during the stage of active bleeding.

Greenwald⁷ has recommended the use of snake venom as a means to control active bleeding in thrombocytopenic purpura.

REPORT OF CASE

A white boy aged 6 years, of Italian parentage, was first seen Nov. 26, 1943 because of uncontrollable epistaxis. The child was perfectly well until one week prior to the onset, when he developed an upper respiratory infection. He was not seen at that time and was permitted to continue at school. There was no history of trauma and no exposure to toxic agents or familial history of ready bruising.

The child was admitted to St. Elizabeth Hospital and examination disclosed the following essential findings:

The patient was definitely anemic in appearance, and hemorrhagic areas were present over the eyes, forehead, lips and lower extremities. Laboratory data revealed hemoglobin 80 to 85 per cent, leukocytes 16,800 and erythrocytes 4,300,000. The platelet count was 42,520, while the bleeding time was thirty minutes and the clotting time three and one-half minutes. Urine examination disclosed numerous white blood cells and a trace of albumin. A diagnosis of purpura hemorrhagica following upper respiratory infection was made.

Treatment consisted of rest in bed, vitamins C and K by mouth, 0.3 cc. of snake venom hypodermically daily and 125 cc. of compatible whole blood daily for two weeks.

About one week after admission the child became irrational at times and complained of headaches and soreness of the neck. At this time there developed blood in the stools; the urine was blood tinged and the platelet count dropped to 3,710.

On December 10, which was the second week of hospitalization, the patient suddenly called for his mother, who was at his bedside, stating that he could not see her. Ophthalmologic examination one week later revealed, in the right eye, doubtful light perception; ecchymotic spots were present on the lids, and the eye appeared slightly prominent. There was limitation of the ocular movements externally, superiorly and inferiorly. The pupil was dilated 3 mm. and fixed to light reaction. The fundus was normal. In the left eye there was doubtful light perception, with injection of the palpebral and bulbar conjunctiva and a staining infiltrate of the cornea at about 5 on the clock dial. The pupil was similar to the right one. The fundus showed a slight blurring of the disk margins, with large hemorrhages at the superior portion of the disk and smaller hemorrhages in the inferior portion.

Diagnosis was made of left corneal infiltrate and left retinal hemorrhages.

It was assumed that the child had suffered some intracranial damage, probably subarachnoid hemorrhage or hemorrhage into the optic nerve sheath and probable hemorrhage into the orbit.

Under therapy the corneal infiltrate healed and sixteen days after the onset of ocular symptoms both disks were pale, showing signs of beginning optic atrophy. The platelet count had risen to 19,640.

On Jan. 12, 1944, which was about six weeks after admission to the hospital, the child was operated on. An abdominal exploration revealed a very large liver extending past the midline to the left and a much enlarged spleen, about four times normal size. A splenectomy was performed. On the second postoperative day the erythrocyte count was 4,660,000 and the platelet count had risen to 327,660. The child continued to improve and two months after admission was discharged from the hospital. At the present writing the eye findings reveal doubtful light perception and bilateral optic atrophy.

From the Ophthalmological and Surgical Departments of St. Elizabeth Hospital.

COMMENT

This case report is of interest (1) because of the rare occurrence of bilateral optic atrophy as a sequela to thrombocytopenic purpura, (2) a splenectomy performed during the quiescent stage of the disease produced an almost immediate return to normal of the blood picture and (3) the eye findings are still unchanged twenty months after the onset of the disease.

3626 West Chicago Avenue—1605 West Chicago Avenue.

Council on Physical Medicine

The Council on Physical Medicine has authorized publication of the following reports. HOWARD A. CARTER, Secretary.

HEIDBRINK OXYGEN TENT ACCEPTABLE

Manufacturer: The Ohio Chemical & Manufacturing Company, Heidbrink Division, Minneapolis.

The Heidbrink Oxygen Tent Model 75B is designed for administering oxygen therapy. The unit is well constructed. The mechanical parts operate as they are designed to do. Diffusion through fabric constitutes a safety factor, as far as accumulation of carbon dioxide is concerned. The unit submitted was tested in a laboratory acceptable to the Council.

Cooling Efficiency.—The air chamber was filled with cracked ice and the tent flaps were tucked under the mattress according to instructions and circulation turned on at "high" with valve for cooling at "cold." Room temperature was 70 F., room humidity 40 per cent.

In 5 minutes the tent temperature was 64 F.; in 15 minutes the tent temperature was 60 F.; in 50 minutes the tent temperature was 55 F., relative humidity 60.

It may be presumed from this experiment that sufficient decrease in temperature of the atmosphere of the tent would result on a hot day in keeping it at or below the point of comfort when it contains a patient. Whether the tendency toward an increase of relative humidity when added to the humidity produced by the patient might become a factor of discomfort was not determined. Since "dryness" was a complaint of a subject in the tent without ice, it seems probable that ice is as important from the standpoint of humidity as it is for cooling.

From further experiments, one may conclude that:

1. Facilities for the control of oxygen and humidity are adequate.
2. With no soda lime in place, a flow of 4 liters or more, and circulator set at 3 or more, carbon dioxide will not accumulate above the manufacturer's limit of 1.5 per cent carbon dioxide.
3. A flow of less than 4 liters per minute of oxygen is inadequate for efficient oxygen therapy.
4. Although circulation of the atmosphere alone eliminates considerable carbon dioxide (diffusion through leaks and fabric) it also eliminates oxygen, thus requiring a higher flow of oxygen.
5. Humidification from ice may be as important from the standpoint of comfort as is its cooling effect.
6. Elimination of carbon dioxide and patient comfort can apparently be controlled by rapid circulation and fast flow of oxygen. However, extremely fast flows of oxygen are then necessary to maintain effective concentrations.
7. Finally, as compared with other tents designed for the therapeutic administration of oxygen, this apparatus is compact and well built.

The Council on Physical Medicine voted to include the Heidbrink Oxygen Tent Model 75B in its list of accepted devices.

Heidbrink Oxygen Tent
Model 75-B.

ALTEX MATTRESS AND PILLOW ENCASINGS ACCEPTABLE

Manufacturer: Expert Bedding Company, 2454 North Halsted Street, Chicago.

An "Altex" mattress and pillow encasings are used by allergic patients sensitive to bedding dusts or to the materials ordinarily used in the manufacture of mattresses and pillows.

"Altex" mattress and pillow encasings are made of bleached white cotton cloth, backed and bonded with synthetic rubber. The mattress encasing has an interior flap which is held in place by the weight of the mattress pressing down on the flap and holding it tight in place. Closure is effected with a button fastener, and the exterior is lowered to cover the button fastener.

The pillow interior flap sheath is used as a block for any heavy dirt or dust and is held in place the same way as the mattress encasing.

All sewing is first done in the raw seams, which are then bias bound, a double stitch being made. All seaming and binding is done on the inside of the encasing.

Perspiration and soap boiling tests were made in the standard perspiration solution used by rubber chemists, and soap tests were made by boiling the samples in 2 per cent soap solution for a period of twenty hours; the results were shown to be negative.

Small bags of the material were sewn and filled with water. Tests showed that in the beginning there was a small drip of water; after two hours there was considerable swelling of the threads and seams, and thereafter the loss of water was by evaporation alone.

In a laboratory acceptable to the Council an "Altex" pillow encasing was examined. It was found to be well made and adequate for the purpose. It stands dilute acid, dilute alkali, various organic solvents and washing very well.

"Altex" encasings are guaranteed for one year from the date of shipment against deterioration, rips and such other factors as may be the result of faulty material and manufacture.

"Altex" encasings are sold on recommendation of the physician alone. None of them are sold through the avenues of retail stores.

The Council on Physical Medicine voted to accept the "Altex" pillow and mattress encasings for inclusion in its list of accepted devices.

Council on Foods and Nutrition

ACCEPTED FOODS

The following additional foods have been accepted as conforming to the Rules of the Council on Foods and Nutrition of the American Medical Association for admission to Accepted Foods.

GEORGE K. ANDERSON, M.D., Secretary.

PREPARATIONS USED IN THE FEEDING OF INFANTS (See Accepted Foods, 1939, p. 156)

Heinz Company, Pittsburgh.

HEINZ STRAINED ORANGE PUDDING contains rice, 50% cream, skim milk powder, cornstarch, salt, sugar, whole eggs, vanilla concentrate ten-fold, fresh orange juice, fresh lemon juice and water to prepare.

Analysis (submitted by manufacturer).—Total solids 24.92%, total sugar as sucrose 13.92%, acidity as citric 0.12%, protein (N X 6.25) 1.73%, fat (by acid hydrolysis) 1.38%, crude fiber 0.05%, ash 0.70%, salt 0.38%, total carbohydrates other than crude fiber by difference 20.94%, calcium 36.0 mg. per hundred grams, phosphorus 39.0 mg. per hundred grams, iron 0.5 mg. per hundred grams, copper 0.1 mg. per hundred grams.

Calories.—1.03 per gram, 29 per ounce.

Vitamins.—	I. U./100 Gm.	Mg./100 Gm.
Carotene	55
Thiamine	0.025
Riboflavin	0.071
Ascorbic acid	3.68

CONTROL OF AIR BORNE INFECTION

Statistics for the years 1933 to 1943 have shown a steadily mounting rate of absenteeism in industry due to respiratory diseases. The rate for 1942 was higher than that of any previous year of the ten year period 1933 to 1942, and in 1943 there was a further striking increase in the frequency of respiratory diseases. Stuart Mudd¹ suggests that the causes of this increasing rate of industrial disability due to respiratory diseases are to be looked for in overcrowding of workers in ill ventilated common carriers, trains, street cars and busses, rather than in the conditions of work in industrial establishments alone. He calculates that for the year 1943 there were lost to industry in the United States through respiratory diseases 128,000,000 man days and 93,000,000 woman days, or over 220,000,000 person days, or more than one third of the total number of person days lost to American industry by disability. This figure represents a waste of labor of about 740,000 persons working for a year.

The Wellss² demonstrated that transmission of infection through the air may be due to droplet infection proper or to the dried residue of infected droplets or droplet nuclei depending on air for the buoyancy that keeps them suspended for longer times and carries them longer distances. Information as to bacterial population can now be obtained in a relatively short time and under control conditions through the employment of recently developed sampling devices. Du Buy and Hollaender³ suggest the following devices for measuring the three physical forms and manner of settling of the air borne organisms: the open plate, any one of the atomizing methods and one of the impinging or sieve devices. The enclosed or living spaces present the principal source for the dissemination of respiratory diseases. The means for the reduction of the bacterial content of living spaces at present

include ultraviolet irradiation, dust suppressive measures and the use of germicidal vapors such as hypochlorous acid, propylene and triethylene glycol. The English investigators Thomas and van den Ende⁴ demonstrated that oiling floors and bedclothes was capable of reducing air borne bacteria in a hospital ward by 90 per cent. Robertson and his co-workers⁵ established that oil treatment of bedding can be adequately achieved by means of water-oil emulsions, which were employed as a final rinse in the laundering process. Tests by the National Bureau of Standards showed that the percentages of oil involved in this process did not constitute a fire hazard. The use of oil on bedclothes brought about a striking reduction in the aerial dispersion of bacteria which ordinarily occurs during bed making. Oiling the floors reduced by 70 per cent the number of air borne bacteria which occurred in the control barracks during the same period of maximum activity. Oiled bedding plus oiled floors effected a further reduction to about 90 per cent of the bacterial counts in the control barracks. Harris and Stokes⁶ studied the use of propylene glycol vapors in bactericidal concentration in wards of a children's convalescent home. The incidence of upper respiratory infection in these wards was much lower than in control wards. The fact that the greater majority of the upper respiratory infections in control wards were common colds provides, in their opinion, additional evidence of the virucidal effect of propylene glycol vapor and may give indirect evidence also of air borne transmission of the common cold.

The bacteriologic studies carried out by Deryl Hart and his co-workers⁷ established that air is an important source of contamination in every operative wound. They also demonstrated that sterilization of the air in the operating room can be accomplished by ultraviolet irradiation. Robertson and her associates⁸ obtained a striking reduction in cross infection in infant wards by ultraviolet irradiation. Wheeler and his associates⁹ describe a carefully controlled clinical study of the effect of the ultraviolet light control of air borne infections in a naval training center. Ultraviolet irradiation of the floors and upper air of barracks housing naval recruits was accompanied by a 25 per cent reduction of respira-

tory illness in those barracks equipped with high intensity sources as compared with illness in the adjacent control barracks. This fact was most noticeable in the early winter months, when illness rates were at a general high level throughout the camp. At this time the reduction of incidence in barracks irradiated with high intensity sources as compared to the controls was approximately 35 per cent.

The practical utility of any control measure predicated on the reduction of the bacterial content of the air will depend on whether or not a large or a small proportion of respiratory disease is air borne. An increased body of evidence indicates that the amount of air borne infection is greater than was formerly believed. The methods thus far developed for the reduction of the bacterial content of living spaces constitute an important contribution to the total problem of control of respiratory diseases. Their practical application presents a number of problems the solution of which will call for cooperation of such specialists as physicians, engineers, architects, air conditioning engineers and manufacturers of special apparatus.

CATGUT TUBING FLUIDS

In 1943 a series of studies were reported on the irritant properties of surgical tubing fluids as a factor in tissue irritations.¹ These demonstrated that marketed specimens of nonboilable surgical gut contained up to 14 per cent by volume of high boiling aromatic carbons in the tubing fluids. These hydrocarbons were related to a coal tar distillate known as "xylene fraction," or solvent naphtha. The investigations also demonstrated that tubing fluids are potent tissue irritants. In the final paper Jenkins and Dunham showed that a sufficient amount of irritant water insoluble hydrocarbon was present in some tubing fluid to account for much of the tissue irritation that follows the use of catgut which had previously been attributed to properties of the catgut itself. The Chicago investigators therefore recommended the elimination of tubing fluid irritants from surgical gut.

Now Bower² reports a series of studies with rabbits and dogs in which he employed catgut sutures tubed in ethyl alcohol containing a percentage of "hi-flash solvents" from 0.1 per cent up to 15 per cent. Tissues surrounding the sutures were examined microscopically. Bower flatly contradicts the claim of Jenkins and his colleagues that the degree of irritant action is proportional to the amount of xylene-like solvent in the alcoholic tubing fluid. Bower also offers evidence

which he labels "conclusive" of the rapid absorbability and lack of irritating action of xylene when brought in contact with normal animal tissues.

The conflicting claims of Jenkins and his co-workers and of Bower require early settlement. The conclusion of Bower that the use of catgut tubing fluids containing "hi-flash solvent" does not produce excessive tissue irritation is surprising in view of the well known irritating properties of xylenes for tissue. If xylene can be proved not to have irritating properties for living tissue, it will be contrary to all past experience. If, however, Jenkins and his colleagues are right, there would seem to be little excuse for continuing to place surgical gut in a solution of potential harm to surgical patients.

PHYSIOLOGIC AND FINANCIAL ECONOMY IN NUTRITION

Satisfactory nutrition of a person or of a group of people depends ultimately on the money available for the purchase of food. Intimately involved in the solution of this essentially financial problem is the discovery of the factors that determine maximum economy in the physiologic utilization of essential nutrients. Generally acceptable standards must be established by which both human nutritional status and diets can be appraised. Now a standard for estimating the nutritional status of persons with respect to the need and the utilization of the vitamins by the body has been considered thoroughly and critically in a recent review by Dann and Darby,¹ who have suggested that five "zones" of nutrition be recognized: (1) nutritional saturation, (2) nutritional unsaturation without functional impairment, (3) potential nutritional deficiency, (4) latent nutritional deficiency disease and (5) clinically manifest nutritional deficiency disease. Nutritional saturation is intended to mean that the body is incapable of increasing its content of a given nutrient even with prolonged ingestion of large amounts. In the case of unsaturated but functionally unimpaired nutrition the body is considered to contain less of a given nutrient than at saturation but still sufficient quantity to prevent the development of functional abnormality detectable by known biochemical or physiologic tests. Potential nutritional deficiency disease is considered to exist in the absence of clinical evidence of deficiency if clinically manifest disease can be precipitated by physiologic stress on the organism or if suitable physiologic or biologic tests yield evidence of decreased reserve functional capacity. Latent nutritional deficiency disease is defined as the mildest clinically detectable form of deficiency disease as indicated by vague, indefinite and nonspecific symptoms which do not permit definite diagnosis but which may be alleviated by the administration of the proper nutrients. Clinically manifest nutritional deficiency disease in its

Sudell, Albert E., Jr.: Hydrocarbon Content of Nonboilable Surgical Gut Tubing Fluid, *ibid.* **118**:285 (Aug.) 1943. Jenkins, Hilger P., and Dunham, Charles L.: Irritant Properties of Tubing Fluids as a Factor in the Tissue Reactions Observed with Surgical Gut (Catgut), *ibid.* **118**:288 (Aug.) 1943.

2. Bower, John O.: The Fallacy of Surgical Gut (Catgut) Tubing Fluids as a Tissue Irritant, *Surg., Gynec. & Obst.* **81**:225 (Sept.) 1945.

1. Dann, F. P., and Darby, W. J.: *Physiol. Rev.* **25**:326, 1945.

mildest form requires laboratory and therapeutic tests for diagnosis; in its severest form the classic clinical syndrome may be diagnosed without recourse to laboratory tests or therapeutic trial.

Determination of the nutritional status of an individual in accordance with these standards is based on data obtained by clinical examination, by biochemical and physiologic tests and by measurement or estimation of the total dietary intake. Dann and Darby caution that clinical examinations usually detect only the well developed deficiency disease. In the diagnosis of mild forms of nutritional disease, clinical examinations must be supplemented by other procedures. The interpretation of most of these procedures, chiefly biochemical tests, is uncertain because these tests have not been correlated adequately in human subjects. They further caution that the dietary standards employed in estimating dietary adequacy are not founded on sufficient data obtained from human subjects. With regard to the use of dietary standards in determining nutritional status, these writers call special attention to a fundamental guiding principle: "Since the dietary standard possesses the properties of a mean, its usefulness as a yardstick for assessment of the mean intake of a nutrient by a population is considerably greater than its usefulness when applied to a valuation of the intake of an individual." The importance of the application of this principle in all nutritional surveys is obvious.

Although the zonal concept of the nutritional status of an individual or, indeed, of a population, as developed by Dann and Darby, may present certain difficulties, particularly with respect to the actual existence of zone 3 and the distinction between zone 4 and zone 5, an appraisal of nutritional status based on this concept is basically sound, and the standards proposed deserve careful consideration.

Current Comment

WHY TRADE NAMES FOR ANTIBIOTICS?

Pharmaceutical manufacturers of the United States made remarkable contributions to the war effort. Outstanding was the production and distribution of penicillin, which saved more lives than can probably ever be estimated. Now some manufacturers, perhaps overly alert to the drive for prestige and profits in the postwar period, seem ready to abandon cooperation and rational therapeutics. At least four firms are actively marketing or planning to market antibiotic preparations such as penicillin and tyrothricin under special trade names. These agents are among the most active and useful compounds that have ever been developed. Some of their usefulness will be lost by confusing their identity. The phenomenal success of sulfonamide therapy in the United States has been partly due to willingness to

make these compounds available under nonproprietary names. When a physician prescribes sulfanilamide, sulfathiazole, sulfadiazine or any other sulfonamide he knows exactly what he is prescribing. Such was not and is not now the case in other countries, where the sulfonamides have been offered under a multiplicity of names. What can manufacturers really gain by abandoning the prestige and publicity that have been given to penicillin and attempting in lieu thereof to establish new names which mean nothing to the medical profession? If their preparations are misused and if antibiotic therapy does not make the progress for which there is promise, these manufacturers must share the blame. The medical profession may well resent these attempts to muddy the clear waters of scientific advancement to conceal a desire for unwarranted individual profits.

BENZYL PENICILLIN

Research on penicillin has been pointed toward finding products of maximum clinical efficiency. Tainter and his associates¹ of the Winthrop Chemical Company claim that the benzyl ester of penicillin is sufficiently superior to ordinary sodium penicillin to merit clinical trial. Benzyl penicillin is prepared by treating free penicillin in an inert organic solvent with an excess of phenyl diazomethane. Any unreacted penicillin is extracted with sodium bicarbonate solution. Evaporation of the solvent yields a resinous product which can be heated well above 100 C. without deterioration. Routine *in vitro* tests against broth cultures of *Staphylococcus aureus* show that this compound is relatively inert, having only one-thirtieth the bacteriostatic titer of sodium penicillin. This inert product, however, is readily activated by the addition of rat kidney extract, rat serum or guinea pig serum, presumably as a result of enzyme action. One half of the bound penicillin is apparently set free as a result of hydrolytic cleavage.² Assuming that a similar hydrolytic regeneration takes place in the animal body, the predictable therapeutic potency of benzyl penicillin would be much greater than that suggested by its low *in vitro* titer. Benzyl penicillin dissolved in a vegetable oil and injected subcutaneously, or given by mouth, was titrated therapeutically on mice inoculated intraperitoneally with multilethal doses of streptococci or pneumococci. Control titers were made with ordinary penicillin. The data thus far obtained show that, when injected subcutaneously, benzyl penicillin has at least three times the therapeutic potency of sodium penicillin. When taken by mouth the therapeutic potency is approximately five times that of sodium penicillin. Given orally, it has substantially the same therapeutic effect as an equivalent weight of sodium penicillin injected subcutaneously. Benzyl penicillin is now being tested on a large scale in clinical cases, and the results will be awaited with much clinical interest.³

MEDICINE AND THE WAR

ARMY

SPECIAL COMMITTEE TO ETO REPORTS ON COMBAT FATIGUE

A recent announcement by the War Department indicates that approximately 90 per cent of the men overcome by combat exhaustion in the European Theater of Operations prior to the collapse of Germany returned to duty as a result of prompt and skilled handling. This announcement was based on a report made by a commission of civilian psychiatrists appointed by the Office of Scientific Research and Development at the suggestion of the Surgeon General of the Army.

In summarizing the observations of the committee, it was stated that army psychiatrists had displayed great courage and ingenuity and had made some notable accomplishments. High quality of personnel, better methods and technics and the fact that psychiatrists are getting to their patients more rapidly are some of the reasons why combat fatigue was treated more successfully in his war than shell shock was in the last war.

The report stresses the fact that the presence of combat exhaustion is no indication of lack of courage. It points conclusively to the fact that soldiers do reach the point at which their systems can undergo no more.

The commission was composed of Dr. John C. Whitehorn, chief psychiatrist, Johns Hopkins University School of Medicine; Dr. John Romano, professor of psychiatry, University of Cincinnati College of Medicine; Dr. Lawrence S. Kubie, associate in neurology, Columbia University College of Physicians and Surgeons, New York; Dr. Karl Menninger, director, Menninger Clinic, Topeka, Kan., and Dr. Leo H. Bartemeir, professor of psychiatry, Wayne University College of Medicine, Detroit.

MEDICAL CORPSMAN AWARDED MEDAL OF HONOR

For his conspicuous gallantry in administering aid to the fallen men of his company at Okinawa and at the same time killing six of the enemy though he was seriously wounded, Robert Eugene Bush, hospital apprentice first class, was recently awarded the Medal of Honor. The citation accompanying the award explained that it was given to Bush "for conspicuous gallantry and intrepidity at the risk of his life above and beyond the call of duty while serving as medical corpsman with a rifle company, 2d Battalion, 5th Marines, 1st Marine Division, in action against enemy Japanese forces on Okinawa Jima, Ryuku Islands, May 2, 1945. Fearlessly braving the fury of artillery, mortar and machine gun fire from strongly entrenched hostile positions, Bush constantly and unhesitatingly moved from one casualty to another to attend the wounded falling under the enemy's murderous barrages. As the attack passed over a ridge top, Bush was advancing to administer blood plasma to a marine officer lying wounded on the skyline when the Japanese launched a savage counterattack. In this perilously exposed position he resolutely maintained the flow of life giving plasma. With the bottle held high in one hand, Bush drew his pistol with the other and fired into the enemy's ranks until his ammunition was expended. Quickly seizing a discarded carbine, he trained his fire on the Japanese charging point blank over the hill, accounting for six of the enemy despite his own serious wounds and the loss of one eye suffered during his desperate battle in defense of the helpless man. With the hostile force finally routed, he calmly disregarded his own critical condition to complete his mission, valiantly refusing medical treatment for himself until his officer had been evacuated and collapsing only after attempting to walk to the battle aid station. His daring initiative, great personal valor and heroic spirit of self sacrifice in service for others reflect great credit on Bush and enhance the finest traditions of the United States Naval Service."

ARMY AWARDS AND COMMENDATIONS

Colonel Charles Langdon Parsons

In recognition of his work in maxillofacial surgery, Lieut. Col. Charles Langdon Parsons, formerly of Boston, was recently awarded the Legion of Merit. As chief of surgical services of a station hospital, Colonel Parsons was credited with initiating, conducting and concluding the work of the maxillofacial clinic of his hospital. Describing his exceptionally meritorious efforts to relieve facial suffering and disfigurement due to battle wounds, the official citation stated that, owing to the high patient census of the surgical service consisting mainly of battle casualties from the Anzio beach-head and the main Italian front, Colonel Parsons' clinic performed most of this highly specialized type of operation for the entire Mediterranean theater. During the period April 1, 1944 to April 1, 1945 the facilities of the unit were taxed to the utmost by the delicate care that each patient required and by the fact that the influx of seriously wounded men almost doubled the normal capacity of the hospital. By working tirelessly for long hours, Colonel Parsons, in addition to his normal duties and in conjunction with his superior surgical ability, compiled an exhaustive history of the experiences of the maxillofacial clinic. Dr. Parsons graduated from Harvard Medical School, Boston, in 1927 and entered the service May 15, 1942.

Captain Cecil J. Hawes

The Bronze Star was recently awarded to Capt. Cecil J. Hawes, formerly of Conway, S. C. According to the citation "While a prisoner of war at Stalag IIA, New Brandenburg, Germany, from January to April 1945, he voluntarily remained at this prison camp to give medical aid to over 800 American and British enlisted men rather than accompany other officers to an officers' camp. Although it was a constant struggle with the German authorities to secure medical equipment, medicines and assistance, he was able to improve greatly the lot of the American and British sick through his untiring efforts, foresight and medical skill. He labored day and night to save the seriously ill and to comfort those in pain. He performed operations under the most difficult conditions and with poor equipment. His cheerful and encouraging attitude was always a morale factor of greatest importance. His exceptionally meritorious achievement was in line with the finest traditions of the medical service and a great credit to himself and the Army." Dr. Hawes graduated from Vanderbilt University School of Medicine, Nashville, Tenn., in 1942 and entered the service July 3, 1943.

Captain John J. Shurtz

Capt. John J. Shurtz, formerly of Eldora, Iowa, was recently awarded the Bronze Star. The citation stated that "he was on assigned duty as surgeon on a United States Army transport when it was torpedoed on Nov. 11, 1943. He remained on board after the order to abandon ship had been given, continued to care for the wounded and supervised their transfer to the rescue ship. Finding insufficient medical and surgical supplies, he obtained a small boat, returned to his transport and, with complete disregard for his own safety and the risks involved, boarded the sinking vessel and went below to obtain the additional supplies. Returning to the rescue ship, he administered medical aid and performed countless surgical operations throughout the night and during the following day. The courage, fortitude and persistence shown by him in the care of patients under adverse and hazardous conditions on an overloaded ship reflect great credit on himself and on the military service." Dr. Shurtz graduated from the State University of Iowa College of Medicine in 1941 and entered the service Sept. 12, 1942.

Major Vance J. Elliott

Major Vance J. Elliott, formerly of Knoxville, Iowa, was recently awarded the Bronze Star "for meritorious services from March 1944 to May 1945 as group surgeon of a heavy bombardment group. Major Elliott has, through diligent and untiring effort, been successful in administering the station hospital so that, from the first, it has been considered a model of its kind, and he has consistently maintained one of the lowest noneffective rates of flying personnel and has been a contributing factor in the combat efficiency of his group. Major Elliott designed a collapsible evacuation airplane litter that enjoyed immediate success and has been instrumental in saving the lives of many men. Major Elliott has shown outstanding ability as a leader and has considerably contributed to the morale of his group and to the medical operations of the Army Air Forces." Dr. Elliott graduated from the State University of Iowa College of Medicine, Iowa City, in 1939 and entered the service Jan. 29, 1941.

Lieutenant Colonel R. Robert Cohen

Lieut. Col. Reuben Robert Cohen, formerly of Havre De Grace, Md., was recently awarded the Legion of Merit for "services from May 1943 to August 1944 at the Army Service Forces Training Center (Ordnance), Aberdeen Proving Ground, Maryland. During that period by his untiring efforts, initiative and superior intelligence he developed a unique and original training program in the field of psychiatry to speed up the mental and emotional transition of enlisted men from civilians into soldiers. The program evolved and put into

operation in all the ordnance training centers was done entirely outside normal duty functions and has resulted in better morale, a reduction in sick call and hospitalization, a saving of training time and the creation of a greater number of well balanced soldiers. His ingenuity, tremendous drive and understanding of human nature have been vital factors in the production of excellent ordnance soldiers, and his work is contributing materially to the success of the war effort." Dr. Cohen graduated from the University of Pittsburgh School of Medicine in 1932 and entered the service April 10, 1941.

DENTAL CORPS OFFICER CITED

Capt. Claude P. Daniel, Dental Corps, formerly of Bogalusa, La., was recently awarded the Bronze Star. The citation read "While a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945, he performed services as chief of dental service and practicing dentist in a general hospital. With improvised makeshift equipment and depleted medical supplies, he labored against great odds and on a starvation diet. At the demand of the Japanese administration he gave dental care to the enemy garrison. His excellent work and the manner in which he performed it were important factors in maintaining endurable associations with the Japanese captors. His continued cheerfulness in the face of arduous and hazardous duties and his unusual accomplishments despite limited facilities were an inspiration to his fellow prisoners of war."

MISCELLANEOUS**INFORMATION WANTED ABOUT
DISCHARGED OFFICERS**

The Directory Department and the Bureau of Information of the American Medical Association are very anxious to obtain the names and present addresses of all physicians who have been released from the armed forces and also the date on which their military service terminated.

These names will be listed in *THE JOURNAL* and in the *Directory Report Service*. Many inquiries are being received daily from physicians who are trying to locate either former colleagues or medical officers whom they met while in military service.

If you know of any physicians who have recently been released from the armed forces, please urge them to send the following information to the Directory Department, American Medical Association, Chicago 10:

1. Full name.
2. Date on which military service terminated.
3. Present address (residence and office).
4. Indicate whether in practice, retired or not in practice.
5. Former permanent address (if different from item 3).

**TRANSFER OF PROCUREMENT AND
ASSIGNMENT SERVICE**

A recent release from the central office of the Procurement and Assignment Service states, in part, that "the functions of the Procurement and Assignment Service of the War Manpower Commission and the functions of the chairman of the War Manpower Commission with respect thereto are hereby transferred to the Federal Security Administrator. There shall be transferred to the Federal Security Agency, for use in connection with such functions, all of the personnel of the Procurement and Assignment Service and so much of the other personnel of the War Manpower Commission and so much of the records, property and funds of the War Manpower Commission as the director of the Bureau of the Budget shall determine to relate primarily to the Procurement and Assignment Service." This transfer was to be effective October 20, at which time Federal Security Agency transportation request blanks were to be used instead of those issued by the War Manpower Commission.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

U. S. Naval Hospital, San Diego: Dysenteries: The Differentiation Between the Protozoal and Bacillary Dysenteries, Dr. John F. Kessel, November 1.

U. S. Naval Air Training Station, San Diego: Recent Developments in Diabetes, Dr. James Sherrill, November 2; Problems in Urology, Lieutenant Commander Rusche.

A. A. F. Regional and Convalescent Hospital, Santa Ana: Tuberculosis Problems, Comdr. W. L. Rogers and Comdr. A. W. Hobby, November 6; The Use of Products of Fibrinogen and Thrombin in Otolaryngology, Capt. Harry P. Schenck, November 20.

Camp Cook Station Hospital, Lompoc: Some Dynamics of Military Neuropsychiatry, Major Alex Blumstein, November 7; Cardiac Emergencies, Lieut. Comdr. Sylvester McGinn, November 21.

Hoff General Hospital, Santa Barbara: Some Dynamics of Military Neuropsychiatry, Major Alex Blumstein, November 7; Cardiac Emergencies, Lieut. Comdr. Sylvester McGinn, November 21.

U. S. Naval Hospital, Corona: Neuropsychiatry, Lieutenant Commander Nichols, November 8; Tumor Pathology, Dr. Edward Butt, November 22.

U. S. Naval Hospital, Santa Margarita Ranch, Oceanside: The Cancer Problem in the Service Personnel, Lieut. J. S. Binkley, November 8; Modern Concepts of Leprosy, Dr. Maximilian Obermayer, November 22.

Torrey General Hospital, Palm Springs: Psychosomatic Medicine, Major Milton Miller, November 6; Headache, Capt. Oscar Sugar, November 6; Peptic Ulcer, Dr. William Poeck, November 20.

A. S. F. Regional Hospital, Camp Haan: Cardiac Emergencies, Lieut. Comdr. Sylvester McGinn, November 6.

Letterman General Hospital, San Francisco: Uremia Following Urologic Surgery, Dr. Donald Smith, November 3.

Station Hospital, Camp Roberts: The Fundamentals of Endocrine Diagnosis, Dr. Roberto F. Escamilla, November 10.

ORGANIZATION SECTION

REPORTS OF OFFICERS

NOTE.—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion. The Report of the Secretary, additional sections of the Report of the Board of Trustees and reports of some councils, bureaus and departments will appear in subsequent issues of The Journal.—Ed.

(Continued from page 465)

REPORT OF THE SECRETARY

To the Members of the House of Delegates of the American Medical Association:

The following report of the Secretary is respectfully submitted:

MEMBERSHIP

At the close of the year 1944 the names of 124,595 members were enrolled. Deaths of members accounted for the removal of 1,952 names from the official list. The enrolment as of Dec. 31, 1943 was 123,586. The gain in membership in 1944 was 1,009.

In practically all instances component societies and constituent associations have retained on their membership rolls the names of members assigned to active duty with the military forces, and those names have also been retained on the official membership list of the American Medical Association. As of Oct. 1, 1945 the number of members enrolled was 126,024 as compared with 125,637 on the same date in 1944.

FELLOWSHIP

The Fellowship roster carried 68,637 names on Dec. 31, 1944 as compared with 70,269 on the same date in 1943. Deaths of Fellows in 1944 numbered 950. The names of 165 Fellows were removed from the roster because of ineligibility, and 412 were dropped because of lapses in the payment of dues. The decrease in the number of Fellows was most largely due to the fact that thousands of Fellows were serving with the military forces in all parts of the world. The Secretary respectfully suggests that the House of Delegates authorize the restoration of the names of all Fellows assigned to active duty on their own request.

The usual table, entitled "Organization of Constituent State and Territorial Medical Associations," is included in this report.

ACTIVITIES OF COMPONENT SOCIETIES AND
CONSTITUENT ASSOCIATIONS

Conditions created by the great war have imposed new and heavy responsibilities and duties on the medical profession of our nation. Thousands of physicians have voluntarily accepted assignment to active duty with the military forces, and the record clearly shows that they have acquitted themselves with great credit. They have served in all parts of the earth and have won the acclaim of commanding officers and men in the ranks in all war theaters.

The depletion in the ranks of physicians available for service to the civilian population has imposed great burdens on those left at home, and they too have served with great credit.

The long continued absence of many of their members and the great demands made on the time and effort of those who were not called for war service have created new problems for our societies. Even so, most of them have carried on earnestly and effectively, though reports indicate that some county societies have found it difficult to continue their activities.

In spite of unusual and difficult conditions growing out of the war, many component societies and most, if not all, of the constituent associations have actually performed in splendid fashion in that they have dealt effectively with many of the problems of the times and in some instances have actually extended their activities in the interest of medicine and in the public interest.

PROPOSED AMENDMENTS TO THE CONSTITUTION AND BY-LAWS

Proposed amendments to the Constitution and By-Laws submitted to the House of Delegates at its last meeting by Dr. C. B. Conklin, delegate of the Medical Society of the District of Columbia, and Dr. A. W. Adson, delegate of the Minnesota State Medical Association, were referred to the Board of Trustees and will no doubt be reported on by that body.

MEMORIALS AND RESOLUTIONS

The Secretary has received copies of several resolutions adopted by official bodies of constituent associations, but it is his understanding that they are to be submitted by delegates representing the constituent associations concerned.

APPRECIATION

Again the Secretary humbly but gratefully extends an expression of his appreciation of the kindly and helpful consideration and aid received from all of the officers and members of official bodies of the Association and many of those concerned with the affairs of its component and constituent societies. In this connection he would offer high commendation for the devoted service of the directing head of every Council, Bureau and Department and the supporting personnel in all offices.

Respectfully submitted.

OLIN WEST, Secretary.

REPORT OF THE JUDICIAL COUNCIL

To the Members of the House of Delegates of the American Medical Association:

During the past year two meetings of the Judicial Council were held in Chicago, one on Dec. 1, 1944 and the other on June 19, 1945. These, in addition to the meetings which were held in conjunction with the meeting of the House of Delegates in June, were sufficient to take care of the routine business and other matters referred to the Council.

The items on the agenda for consideration at the Council meetings were:

1. Applications for Fellowship in the American Medical Association which were questioned because of information contained in the biographic files of the American Medical Association.

2. The proposed amendments to the Constitution and By-Laws which were referred to the Council by the Board of Trustees. These amendments were introduced in the House of Delegates at its meeting in June 1944 and referred to the Board of Trustees, which, in turn, referred them to the Judicial Council. They concerned membership in the American Medical Association and consequently were considered by the Council. Reports were completed on two of the proposed amendments, the third being delayed temporarily because of the inability of the Council to secure a copy of the constitution and by-laws of the constituent society concerned.

3. There were many questions in regard to unethical advertising inquiries on the ethical relationship of doctors with hospitals and government agencies operating medical services and questions from physicians as to their right of appeal from decisions of constituent associations. Other questions on the same subjects were answered either by correspondence with headquarters or the Chairman of the Council or by personal interview with one of its members.

PROFESSIONAL RELATIONS

The members of the profession, however, are more disturbed by some doubts as to the ethical principles governing relationship between doctors and members of the various cults. Many requests were for information regarding this relationship. It seems strange that such a condition still exists, for in the reports of the Judicial Council in 1936 and 1938 a considerable portion of the reports was devoted to this matter. The increased privileges which have been granted to the cults in some of the states have made this a matter of great importance

to our members and to the public. As an accurate understanding of the principles involved is so necessary for the ethical practice of our profession, we are taking the liberty of quoting the decision rendered and reported in 1936:

There are several general ethical principles underlying cult practice in its relation to medical practice as carried out by doctors of medicine. Primarily the basis for an ethical code is the well being of the people at large, who are dependent on the profession of medicine for their health. The profession of medicine is the custodian of the accumulated knowledge in medicine and should use it for the benefit of humanity. This knowledge, technical in nature and developed by experience, can be interpreted to the body of the people only by persons educated to understand it and trained to apply it. Of all those professing to heal the sick only the doctor of medicine has sufficient education and training to make use of the information already accumulated and keep abreast of that being developed continuously. We grant that even though this is true no one is compelled to choose only from this group in selecting his medical attendants. The individual may elect to receive his medical care from himself, his neighbor, osteopathy, chiropractic, naturopathy or Christian science, but he is not entitled while under the care of such irregulars to demand that the man educated in scientific medicine furnish opinion and advice to one so far deficient in education that he cannot so understand and apply that opinion and advice as to be able to make satisfactory use of it. Such degrading consultation would cheat the patient out of that which he might expect and the subsequent failure of results bring discredit on the science of medicine. If this is true of the occasional individual consultation, how much greater it must be in the case of repeated or continual miscegenation!

The Judicial Council is in receipt of much correspondence attempting to justify if not to advocate consultations between doctors of medicine and chiropractors, osteopaths, Christian scientists and other cultists and irregular practitioners; also appearance before their societies, teaching in their schools, and their admittance to hospital practice on a parity with the medical profession. The universal argument for all the procedures mentioned is based on the false premise "to work them gradually into regular medicine." One of our principles of ethics is as follows. "The obligation assumed on entering the profession . . . demands that the physician use every honorable means to uphold the dignity and honor of his vocation, to exalt its standards and to extend its sphere of usefulness." Such specious argument as mentioned above seems to the Council to lack substance and be unreal. It seems impossible that knowledge gained through years of scientific laboratory work and teaching can be assimilated by those of less preliminary training and use of scientific methods of investigation and practice ever to fit them to enter a profession the dignity and honor of which, the standards and sphere of influence of which, we are obligated to uphold, exalt and extend for the service the profession can render to humanity. We further are of the opinion that it is just as impractical to suggest that the small percentage of cult practitioners will through close relationship with the membership of our profession be raised to our professional standards as it is to expect the few rot speckled apples in the apple barrel to become whole because of the preponderance of sound ones. We believe in continuous, complete separation between the true and the specious physician. Our traditional responsibility for the dissemination of sound scientific treatment for the people and for protection against the insidious influence of the weaker among our own is ever present. If and when the time comes that government through legislation places the cultist on the same legal plane with us, we must strive to maintain the aristocracy of learning and culture. A physical and professional separation as complete as is possible should be established and maintained.

The Judicial Council, having jurisdiction on all questions of ethics, is very much impressed by the lack of knowledge of the Principles of Medical Ethics of the American Medical Association by a great many members of the medical profession. It also notes with regret that there is too little instruction or explanation of these principles given during the students' course in the medical schools. Some medical schools include medical ethics in their courses of instruction, while others may have one or two lectures on the subject during the college year, but this does not accomplish proper indoctrination into the traditions of our profession. The importance of this condition is augmented greatly by the fact that between 7,000 and 8,000 graduates have been inducted into the military forces at the end of a nine month internship immediately following graduation. These men have had but little, if any, information regarding the Principles of Medical Ethics of the American Medical Association or the rules of conduct of a constituent association of a state in which they may locate after release from military service. In time of peace, this condition would be somewhat corrected by association during their internship with men serving on the visiting staffs of hospitals and by attending meetings of the local component society where the rules of conduct are often discussed and the practical applica-

tion of the Principles of Medical Ethics and rules of conduct are demonstrated. It is conceivable that the professional success of a young doctor may often be handicapped by the injudicious or unwise violation of these principles, thus proving a severe handicap for him to overcome. A great number of medical military officers will be released in the near future who may have little knowledge or understanding of our Principles of Medical Ethics. Therefore it would seem wise for the various state associations to inaugurate and encourage a course of instruction on the Principles of Medical Ethics and the rules of conduct, given either under the auspices of the state association or by its component societies. This, we feel quite certain, is as necessary to the doctor's ultimate and complete attainment of his aims as are any of the other plans for a continued postwar graduate course.

DETERMINATION OF POLICIES

It is quite evident that a certain weakness in our organization is due to a lack of understanding of the manner in which our Association functions in determining its policies. This condition is found to exist among members of practically every component society. It seems to us that it would be well worth while to develop some program by which one, when admitted to membership, would be indoctrinated in medical affairs. This would consist not only in the teaching of the Principles of Medical Ethics of the American Medical Association and the rules of conduct of the constituent associations but also of the manner in which the American Medical Association functions, beginning with the component society's relationship to the constituent association and its relationship to the parent association and describing in detail the manner in which matters developed in the component societies are brought to the state associations and thence to the national House of Delegates to become finally a policy of the organization. The democracy of the American Medical Association should be stressed emphatically and the fact that the policies are adopted only by the action of the House of Delegates. A complete description of the structure and procedure of the American Medical Association should be taught. Perhaps this might be accomplished by the publication of a pamphlet with a graph to show the structure and some illustrated cases of procedure to make the matter more readily understood.

DR. GEORGE EDWARD FOLLANSBEE

It is with profound sorrow we note the death on Jan. 1, 1945 of our late member, Dr. George Edward Follansbee. Associated with the Judicial Council for twenty years and serving as its Chairman for sixteen of them, Dr. Follansbee won the affection and respect of its members. His fine, judicial mind, years of experience and knowledge of the policies and traditions of our Association made him an invaluable member. He was admired, respected and loved not only for his tolerance, kindness and patience toward those presenting their problems before the Council but also for his uncompromising attitude toward any proposed action which might tend to lower the standards, ideals or dignity of the medical profession. His ability to write opinions lucidly and succinctly was cause for favorable comment on many occasions. His activities were constantly directed toward maintaining the ideals of our Association, exalting the dignity of the medical profession and increasing its respect among the general public. Dr. Follansbee's many years of unrelenting service in the interest of the American Medical Association makes his death a great loss to the entire profession but in particular to the Council, where we miss his sage advice and well balanced judgment. To us the place left vacant by his death will never be completely filled.

Respectfully submitted.

EDWARD R. CUNIFFE, Chairman.
WALTER F. DONALDSON.
LLOYD NOLAND.
JOHN H. O'SHEA.

REPORT OF THE BOARD OF TRUSTEES

Council on Physical Medicine

At the 1944 annual session of the House of Delegates a name of the Council on Physical Therapy, so called during the nineteen years of its existence, was changed, by action of the House on recommendation of the Council and the Board of Trustees, to the Council on Physical Medicine. The change was felt to be desirable since physical agents coming under the scope of the Council's work include diagnosis as well as therapy and because the Council has for some time interested itself in occupational therapy, which is a branch of the broad field of physical medicine, and for other reasons.

With its new name the Council on Physical Medicine will continue as it has always functioned but will devote additional attention to problems coming under the broader scope.

The restrictions placed on raw materials due to the need for war continued through 1944. Development of some new therapeutic and diagnostic equipment was limited. New equipment developed remained secret to the Army and Navy service and practically no new apparatus was offered for sale to physicians. Many manufacturers almost entirely confined their output to the requirements of the armed services or for lease commitments, while others converted their facilities to the fabrication of materials of war. For these reasons fewer appliances have been submitted to the Council, and investigations of apparatus have been greatly curtailed.

Because specialists have been too busy in private practice to write papers or have been engaged with military duties, only a limited number of authoritative articles about physical medicine were prepared, considered and published. The Council has published eighteen reports and reported on fourteen devices in THE JOURNAL. Several other pieces of equipment have been investigated, but reports on them have not yet been published.

Each year the Council does a formidable amount of work investigating apparatus submitted. In some instances the investigations have revealed that products submitted have little or no value and, based on the reports of the Council and its investigators, in many instances the promoter will agree to withdraw the product from the market. In view of such cooperation, the Council holds its report in abeyance. However, the Council does not hesitate to publish reports announcing to the profession the true value of a questionable appliance. Many inquiries about physical medicine have been referred to the Council and have received attention.

DIATHERMY APPARATUS

Diathermy apparatus, as all physicians are aware, generates high frequency electrical energy which is comparable to that generated by radio transmitters. Not all of the electrical energy is absorbed by the tissues undergoing treatment; some of the high frequency energy escapes and is radiated into space, and this energy will in some instances unknown to the physician interfere with radio communication. The Council has cooperated with the Federal Communications Commission in an effort to solve this problem. The commission has carefully surveyed the field in which high frequency electrical energy is used and has recommended three channels for medical and industrial heating applications. The commission expects that all diathermy equipment manufactured henceforth will maintain the frequency within the limits prescribed.

Although the commission has not declared a time limit, a reasonable period of probably five years will doubtless be allowed for physicians to liquidate their diathermy equipment, screen it, dispose of it or purchase apparatus which will be frequency controlled.

PUBLICATIONS

A completely revised Handbook on Physical Medicine containing several new, authoritative and valuable articles has been published and is ready for distribution.

The Manual of Occupational Therapy, consisting of articles first published in WAR MEDICINE, has been assembled and made into pamphlet form. The American Occupational Therapy Association and the Subcommittee on Rehabilitation of the National Research Council, together with specialists of the Council in this field, have cooperated in its preparation.

COUNCIL CONSULTANTS

Physical medicine embraces many specialized fields. The Council on Physical Medicine, consisting of twelve members, can scarcely be expected to have all the critical and authoritative information regarding all problems that are presented to it, and it is therefore fortunate in having groups of consultants, giving their services gratuitously as do the members of the Council, who advise on problems arising in specialized fields. There are consultants on audiometers and hearing aids, on respirators, on roentgen ray equipment, on contraceptive devices, on ophthalmic devices, on electrocardiographs, on education and on artificial limbs. Consultants on occupational therapy and on electroencephalography recently have been added to this group.

EDUCATION

In all matters pertaining to postgraduate training of physicians planning to specialize in physical medicine and to the education of physical therapy and occupational therapy technicians, the Council has consulted with other authoritative groups in the field. The Council has cooperated with the Council on Medical Education and Hospitals, the American Registry of Technicians of the American Congress of Physical Medicine and the American Physiotherapy Association.

To assist in promotion of sound physical therapeutic measures in the medical corps of the armed forces, the Council prepared two sets of slides which may be borrowed for instructional purposes. These slides are now available to schools of medicine, medical societies, clinics and interested civilian medical groups. The Council is now undertaking, with the help of its consultants, the revision of films for instructional purposes.

AUDIOMETERS AND HEARING AIDS

The manufacturers of hearing aids were very active during the war. Hearing aids were considered vital to the war effort, and, since the amount of raw materials required to make one unit is very small, governmental agencies made materials available. With the help of its consultants on audiometers and hearing aids the Council has prosecuted its examinations of audiometers and hearing aids and has published reports on them. The Council greatly appreciates the cooperation and advice it has received from the American Academy of Ophthalmology and Otolaryngology, the American Otolological Society, the American Laryngological, Rhinological and Otolological Society and the American Society for the Hard of Hearing and its several chapters.

OPHTHALMIC DEVICES

Orthoptics, which deals with the defective habits of seeing and with the defects of binocular vision and of ocular motility, has been given consideration by the Council. The consultants on ophthalmic devices, who are also members of the American Committee of Optics and Visual Physiology, have given valuable assistance in the investigation of charts for testing vision, muscle balance, instruments for orthoptic training and other devices utilized in the ophthalmic field.

ARTIFICIAL RESPIRATION AND RESUSCITATION

At the request of the Council on Physical Medicine the Board of Trustees awarded substantial grants for investigation of artificial respiration and resuscitation. Five years ago a grant was awarded for a survey of artificial respiration which has now been completed, and the report of this survey is ready for publication. The information gathered by the investigators confirms the Council's stand concerning the acceptance or rejection of devices for administering mechanical respiration. Since apparatus is seldom on hand in an emergency, the Council believes that every person should know how to give artificial respiration by an approved manual method. Critical evidence indicates that the first five minutes of complete anoxia are the most important, and artificial respiration should be applied within this period if any hope of survival of the patient is expected. The chances of survival are considerably lessened if artificial respiration is applied later. Hence the Council has cooperated with the American Red Cross in educational activities promoting the manual method of artificial respiration.

(To be continued)

Bureau of Information

SUMMARY SHEETS FROM VERMONT
AND VIRGINIA

Completed county summary sheets have been received from counties in Vermont through Dr. Benjamin F. Cook, secretary, Vermont State Medical Society, and from Virginia through Miss Agnes V. Edwards, executive secretary, Medical Society of Virginia.

The accompanying tables give data from selected counties in these states. The column giving the number of persons per telephone is used as one index of the economic status of the area. Many physicians over 65 years of age are carrying on large practices and are doing much to maintain the health of communities. They are not included in computing physician population ratios, however, as the future needs of the communities will be largely dependent on younger physicians.

1. Bureau of Census, estimated population 1913.

2. Bureau of Census, population 1910.

3. Based on 1910 figures, American Telephone and Telegraph Company.

A current knowledge of needs of communities for doctors is essential if adequate help is to be given veteran medical officers in their problems of medical practice. These needs can be indicated on the summary sheets under "Remarks" by the state and county secretaries and are then available to inquiring medical officers. Frequent reports from state and county medical societies about needs of communities for doctors will help maintain current files and will increase the service of the Bureau.

With the information available on a completely filled out summary sheet, it is readily possible for an interested medical officer to make an initial selection of areas in which he might like to practice. Since vacancies are held open in many communities for doctors now in military service, further investigation by direct correspondence with state and county medical societies will always be necessary to insure an accurate report of the needs of individual communities.

Washington Letter

(From a Special Correspondent)

Oct. 15, 1945.

Discussion of Psychiatric Problems by Canadian Health Official

Psychiatric problems of returning veterans will be discussed here by Major Gen. G. Brock Chisholm, deputy minister of national health and welfare in Canada, who is to speak on the first of two programs on "The Reestablishment of Peacetime Society; Responsibilities of Psychiatrists," Tuesday and Wednesday in Interior Department Auditorium. General Chisholm will spend the week in conferences with U. S. officials and psychiatrists concerned with veterans' problems. He conferred today with officials of the U. S. Public Health Service and Tuesday was to talk at the Navy Medical Center, Bethesda, Md. He will be in Baltimore Thursday to visit the Henry Phipps Psychiatric Clinic at Johns Hopkins Hospital and the Sheppard and Enoch Pratt Hospital. Friday he will inspect St. Elizabeths Hospital in Washington. Head of the Canadian Army Medical Corps during the war, General Chisholm has been active in creating an understanding of servicemen's points of view. Also taking part in the program will be Secretary of Commerce Henry Wallace, who will appear on a panel discussion with government officials and psychiatrists Wednesday evening. With him in the discussion will be Undersecretary of the Interior Fortas, Gen. Omar N. Bradley, Veterans Administrator; Watson B. Miller, federal security administrator; Anthony Hyde, deputy director of the Office of War Mobilization and Reconversion; Major Gen. Paul R. Hawley, acting Surgeon General of Medical Service of the Veterans Administration, and Dr. Harry Stack Sullivan, president, Washington School of Psychiatry. Both programs, open to the public, are sponsored by the William Alanson White Psychiatric Foundation.

Miniature X-Ray Apparatus Is Demonstrated

In connection with the fiftieth anniversary of the discovery of the x-rays by Wilhelm Conrad Roentgen a new miniature x-ray apparatus, developed after three years' research, which speeds up the process so that a thousand chest pictures may be taken in an eight hour day, is being demonstrated. The 70 mm. unit is used for screening indications of the disease and is operated with the use of a recent discovery known as a phototimer developed by Dr. Russell H. Morgan and Dr. Paul Hodges of the University of Chicago. Capt. Milton Birnkrant, Army physician associated with the U. S. Public Health Service, is demonstrating the miniature x-ray equipment in New York and states that, while previously an x-ray picture cost 60 cents, the new, smaller picture can be taken for 3 cents. He declares that the rapid survey of whole communities and industries is now feasible.

Security Restrictions Lifted on Powerful Rat Poison

Security restrictions have been lifted on publication of information about ANTU, rat poison so powerful that 1 pound could kill 300,000 rats. It is not dangerous to man. The poison has been a closely guarded secret during the war. Facts about the poison are revealed in *Public Health Reports*. Credit about the discovery goes to Dr. Curt P. Richter of Phipps Psychiatric Clinic, Johns Hopkins Hospital, Baltimore. The word ANTU is from the initial letters of the chemical name alpha-naphthyl thiourea. It is a fine gray powder with little odor or taste. It acts exclusively on rats, killing in an unusual way by causing a dropsy of the lungs so great that the animals are drowned in this fluid from their own bodies.

Navy Losses Through Mental Disorders

Vice Admiral McIntire, submitting figures to the House Naval Affairs Committee prepared by Capt. Francis J. Braccand, chief of the navy's neuropsychiatric division, said that the Navy, with a wartime strength of 3,385,000, lost the services of 171,267 men through emotional and mental disorders, insanity and inaptitude. At the conclusion of his testimony Chairman Vinson, Democrat of Georgia, recommended that the Navy establish its own hospital for mental disease "in the central part of the United States." He asked Admiral McIntire to come before the committee some time before Christmas with recommendations.

Meeting in Washington of Airlines Medical Directors

The executive council of the Airlines Medical Directors Association met here to discuss problems attendant on expanded commercial air travel. The party was headed by Dr. Hodges McKnight of Fort Worth, Texas, president, representing American Airlines, and attending were Col. A. D. Tuttle, Chicago, United Air Lines; Dr. Frederick H. Shillito, New York, Pan American Airways; Dr. Francis N. Kimball, New York, American Export Airlines, Inc.; Dr. Howard K. Edwards, Miami, Eastern Airlines, and Dr. L. G. Lederer, medical director and director of personnel administration of Pennsylvania-Central Airlines.

Extension of Child Care Centers Predicted

Chairman Fritz G. Lanham of the House Public Buildings and Grounds Committee, father of the Lanham act, has predicted that the Federal Works Agency will keep the wartime child care centers in operation past the scheduled October 31 closing date. The FWA states that extension of the program rests entirely with Congress. George H. Field, commissioner of the FWA Bureau of Community Facilities, says that the agency requires some of the \$19,000,000 of Lanham act money the House Appropriations Committee plans to repeal if the centers are to be kept open. There has been a nationwide clamor from mothers for continuance of the program.

Two Distinguished Women Scientists Honored

Drs. Ida Bengston and Alice Evans were honored by Surgeon General Thomas Parran and more than a hundred of their friends and colleagues on their retirement after being with the U. S. Public Health Service since 1918 and 1916 respectively. Dr. Evans identified undulant fever in 1923, contracting the disease during her work on it. Dr. Bengston, during 1935 and 1936, prepared the standard for gas gangrene toxins and anti-toxins now used by the League of Nations Health Committee in Copenhagen.

Reduction in Size of Army

Secretary of War Patterson reports that all but 1 million of the 8 million men in the Army will be discharged by next July. It is to be expected that a proportionate number of medical officers will be released to civilian duty. Mr. Patterson declared that personnel will be released as fast as possible. He said that the Army's discharge rate is now 26,000 a day and that more than a million men have been released since V-E day. He argued for retention of the draft, declaring that the Army is counting on 50,000 draftees and 30,000 volunteers each month.

Coming Medical Meetings

American Medical Association House of Delegates, Chicago, Dec. 3-6.
Dr. Olin West, 535 N. Dearborn St., Chicago 10, Secretary.

American Ophthalmological Society, Hot Springs, Va., Nov. 12-14.
Dr. Walter S. Atkinson, 129 Clinton St., Watertown, N. Y., Secretary.

American Society of Tropical Medicine, Cincinnati, Nov. 12-15. Dr. Joseph S. D'Antoni, Tulane Ave., New Orleans 13, Secretary.

Indiana State Medical Association, French Lick, Nov. 6-8. Mr. Thomas A. Hendricks, 23 E. Ohio St., Indianapolis 4, Secretary.

Southern Medical Association, Cincinnati, Nov. 12-15. Mr. C. P. Loran, Empire Bldg., Birmingham 3, Alabama, Secretary.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CONNECTICUT

Personal.—Dr. John E. Flaherty, Rockville, has been elected chairman of the state fish and game board for two years. —Dr. Clarence G. Thompson, Norwich, has been appointed health officer of the town of Preston.

Research on Penicillin.—The New Britain General Hospital, New Britain, has been given funds by the Office of Scientific Research and Development to organize a research laboratory to study the effectiveness of penicillin as a curative agent in the treatment of experimental syphilis in human beings. The investigation is part of a cooperative study being carried out in several large centers in the country under the direction of a subcommittee on venereal diseases of the National Research Council. Dr. Paul D. Rosahn, pathologist in charge of laboratories at the New Britain Hospital, has been named investigator by the Office of Scientific Research and Development.

ILLINOIS

Forty Years as Postmaster.—Dr. Guy F. Turner, Long Point, was entertained at a dinner recently in recognition of his completion of forty years of service as postmaster, it is reported. He retired from the position on August 31. The celebration was also said to be in honor of Dr. Turner's birthday.

Chicago

Robert Cunningham Joins the "Modern Hospital."—Mr. Robert M. Cunningham Jr., associate editor of *Hygieia*, has been named managing editor of the *Modern Hospital* of Chicago, succeeding Alden B. Mills who left October 13 to become superintendent of the Huntington Memorial Hospital, Pasadena, Calif. In addition to his work on *Hygieia*, which is the health magazine of the American Medical Association, Mr. Cunningham has been since 1937 director of public relations on a part time basis for Evanston Hospital, Evanston, Ill. He has written extensively for national magazines on medical and related topics. Before joining *Hygieia* in 1941, Mr. Cunningham was for three years a member of the staff of the Chicago Plan for Hospital Care, the nonprofit hospital prepayment organization. He served variously as assistant to the executive director, head of the hospital department and director of enrolment and public relations.

Faculty Changes at Illinois.—Effective September 1 the following members of the faculty at the University of Illinois College of Medicine have been promoted to the rank indicated:

- Dr. Arthur R. Cooper, Oak Park, Ill., to professor of anatomy.
- Dr. Roy L. Webb, Charleston, W. Va., to professor of anatomy.
- Dr. Abram R. Hollender, Miami, Fla., to professor of otolaryngology.
- Dr. Warren S. McCulloch, to professor of psychiatry.
- Dr. William H. Cassels, to professor of surgery.
- Robert H. Krehbiel, Ph.D., to associate professor of anatomy.
- Dr. Oliver E. VanAlyea, to clinical associate professor of otolaryngology.
- Dr. Richard W. Watkins, to clinical associate professor (Rush) of otolaryngology.
- Dr. Ford K. Hick, Oak Park, Ill., to associate professor of medicine.
- Dr. Theodore J. Wachowski, to associate professor of radiology.
- Dr. Benjamin D. Braun, to clinical assistant professor of radiology.
- Dr. Harold C. Lueth, Evanston, Ill., to associate professor of medicine.
- Dr. James B. Eyerly, to clinical professor of medicine.
- Dr. Loren W. Avery, to clinical professor of neurology.
- Dr. Ben W. Lichtenstein, to associate professor of neurology.
- Dr. Hiram J. Smith, to associate professor of ophthalmology.
- Dr. Carl Apple, to associate professor of ophthalmology.
- Dr. Louis Bothman, to clinical professor of ophthalmology.
- Dr. Ralph Spaeth, to assistant professor of pediatrics.
- Dr. Gertrude E. Howe, Cincinnati, to assistant professor of pediatrics.
- Dr. Carl Irenicus Jr., to assistant professor of surgery.
- Dr. Roy O. Riser, Park Ridge, Ill., to assistant professor of ophthalmology.

This year for the first time the University of Illinois is using the word clinical for its part time faculty members who are in the clinical departments.

IOWA

Clarence Van Epps Retires.—Dr. Clarence E. Van Epps has retired from his administrative activities at the State University of Iowa College of Medicine, Iowa City, after twenty-six years in the position. The state medical journal reports that Dr. Van Epps will continue his work on a part time basis.

Investigation of Abortion Ring Follows Physician's Arrest.—Investigation into activities of an alleged abortion ring was started September 22 in Rockford following the arrest of Dr. Manly H. Shipley, Rockford, Ill., according to the *Davenport Times*. A newspaper report indicated that a woman had informed the state's attorney's office that the physician had performed an illegal operation. At the time of a raid on Dr. Shipley's offices 7 women were taken into custody for questioning; 5 were patients, according to the physician, and the other 2 were said to be nurses employed by him.

Course on Tropical Diseases.—A course on laboratory diagnosis of malaria and tropical diseases will be held at the Iowa State Hygienic Laboratory, Iowa City, October 29-November 3. The course is sponsored by the State University of Iowa College of Medicine and the state department of health in cooperation with the U. S. Public Health Service. Travel and other expenses of those who attend will be met with funds derived from the public health service. The course will be similar to one conducted July 23-28 (THE JOURNAL, May 19, p. 216).

MICHIGAN

Research of Virus Diseases.—Research on virus diseases will be initiated at the Wayne University College of Medicine, Detroit, this fall, following acceptance by the Board of Education of a grant of \$2,500 plus equipment from Dr. Hugo A. Freund, Detroit, and the children's fund of Michigan, according to the *Detroit Medical News*.

State Medical Election.—Dr. William A. Hyland, Grand Rapids, was named president-elect of the Michigan State Medical Society at the meeting of the council on September 18. Dr. Ray S. Morrish, Flint, was inducted into the presidency. The next annual session of the State Medical Society will be held at the Book-Cadillac Hotel, Detroit, September 25-27.

Dr. Pelouze Lectures on Venereal Disease.—"The Modern Treatment of Gonorrhea" will be the theme of a series of lectures to be given throughout the state of Michigan beginning in Lansing, October 30, by Dr. Percy S. Pelouze, Philadelphia. The series will be presented under the auspices of the council and committee of postgraduate medical education of the Michigan State Medical Society.

Hospital Urges Patients to Return to Former Physicians.—The staff of Mount Carmel Mercy Hospital in Detroit has recently distributed to its members a placard with the following notice printed on it and intended to be posted in the waiting room of the various staff members:

If you have been a patient here because your doctor has been a member of the armed forces, we suggest that you contact him upon his return.

NEW YORK

Cancer Teaching Day.—On November 1 a cancer teaching day will be held at the St. Lawrence State Hospital, Ogdensburg, under the auspices of the Medical Society of the County of St. Lawrence, St. Lawrence State Hospital, Medical Society of the State of New York, and the New York State Department of Health division of cancer control. Speakers will include:

- Dr. Morton L. Levin, Albany, Cancer Incidence, Prevalence and Mortality.
- Dr. Cushman D. Haagensen, New York, Cancer of the Breast.
- Dr. Clyde L. Randall, Buffalo, Diagnosis and Treatment of Cancer in the Female Pelvis.
- Dr. Lloyd F. Craver, New York, Leukemias and Hodgkin's Disease.

New York City

Proposed Alfred Smith Memorial.—On October 4 a campaign to raise \$3,000,000 to construct the Alfred E. Smith Memorial Hospital was launched with a dinner at the Hotel Waldorf-Astoria. The memorial will be a sixteen story addition to St. Vincent's Hospital. The 250 beds planned in the new structure will include 100 additional ones in the charity wards and 80 more for semiprivate patients. The hospital will be a "living memorial" perpetuating Alfred Smith's services to his fellow man. The dinner to launch the campaign for funds was held on the first anniversary of his death.

Neva R. Deardorff to Establish System for Health Insurance Plan.—Neva R. Deardorff, Ph.D., New York, assistant executive director of the Welfare Council of New York City, has been appointed to the staff of the health

Insurance Plan of Greater New York to establish a uniform method of collecting and correlating all records of service to members of the plan, according to the *New York Times*. In announcing the appointment it was stated that there is a great need to know the frequency and duration of illness, the need for medical care and the frequency of doctor's services rendered.

Lectures to the Public.—"Medicine Today" is to be the theme of the Laity Lectures Series for 1945-1946 under the auspices of the New York Academy of Medicine. The lecturers will be:

Dr. John F. Fulton, New Haven, Conn., November 8, *Medicine Today*.
Dr. Willard C. Rappleye, New York, November 29, *The Making of the Doctor*.

Drs. Basil C. Maclean, Rochester, and Donald M. Clark, Peterborough, N. H., December 13, *The Ways and Means of Modern Medicine*.
Edwin J. Cohn, Ph.D., Boston, December 27, *Research in the Medical Sciences*.

Dr. Edward S. Rogers, Albany, January 10, *The Layman's Part in Medicine*.

Dr. Dean A. Clark, Washington, D. C., January 24, *Economics and Medicine*.

Medical College Plans Expansion.—The dean of two major departments, that of biophysics and one on humanities in relation to medicine, is included in the general program of expansion planned at the New York University College of Medicine, New York. In addition the program includes the introduction of a premedical year in the college to graduate physicians in seven instead of eight years after high school. According to the *New York Times* the four points in the program are:

Full recognition of medicine as a social science, with emphasis both in teaching and in practice on the environment and psychologic aspects of illness.

Increased instruction in the physical sciences of biology, chemistry and especially physics.

A planned research program based on the coordinated work of many departments and directed toward the solution of selected major medical problems.

A plan of community medical care to provide comprehensive diagnosis and treatment under a prepayment group practice system.

In a statement Dr. Donald Sheehan, New York, acting dean of the medical college, said that "emphasis will be placed on the social and psychologic causes of illness and on the effects of living and working conditions on human welfare. These factors are coming to be the chief cause of ill health in modern urban communities. To give the doctor breadth of view he must also know something of the history, the ideals and the economic problems of medicine. To offset the tendency to make the modern doctor a mere technical specialist, a new department dealing with the humanities in relation to medicine is projected."

NORTH CAROLINA

Robert Stimpson Resigns as Vital Statistics Head.—

Dr. Robert T. Stimpson, Raleigh, who has been director of the division of vital statistics of the North Carolina Board of Health, has resigned to enter private practice in Winston-Salem. Dr. Stimpson, who graduated at the University of Pennsylvania School of Medicine, Philadelphia, in 1927, joined the state board of health in January 1932 as assistant director of the division of vital statistics.

New Head of Pathology Department.—Dr. Robert P. Morehead, Wake Forest, associate professor of pathology, has been appointed director of the department of pathology and bacteriology at Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, to succeed Dr. C. C. Carpenter, who asked to be relieved of the direction of the department because of the pressure of administrative duties as dean. Dr. Carpenter will continue to be a member of the staff of the department, assuming the title of professor of legal medicine and director of the laboratory of clinical pathology.

Meeting of Pathologists.—The North Carolina Pathological Society met at the Bowman Gray School of Medicine of Wake Forest College, Winston-Salem, on September 7. The program included the following:

Col. Alfred Blumberg, M.C., Fort Bragg, Rhinosporidiosis.
Dr. Vaty Menkin, Durham, Leukopenia and Inflammation.
Dr. Bernard Black-Schaffer, Durham, Pathogenesis of Purpura Meningococcemia.

Dr. Lalla Iverson, Durham, Chloroma, Report of Two Cases.
Dr. Hugh Dorch Jr., Durham, Sensitization to Placental Products as a Cause of Toxemia of Pregnancy.

Dr. Paul Kimmelsiel, Charlotte, Lymphoid Hyperplasia of the Thyroid and Ischemic Infarctions of the Prostate.

Dr. Frank W. Konzelmann of Atlantic City, N. J., president of the American Society of Clinical Pathologists, spoke at the dinner meeting on "The Economics of the Practice of Pathology." At the business meeting the following officers were elected: Dr. Hershel C. Lennon, Greensboro, president, Dr. Kimmelsiel vice president and Dr. Wilbur C. Thomas, Winston-Salem, secretary-treasurer.

Personal.—Dr. George A. Hays, who recently returned to the United States from Alaska, where he was executive director of the Territorial Department of Health (*THE JOURNAL*, August 4, p. 1040), has been placed in charge of the Charlotte Health Department pending the appointment of a successor to Dr. William R. Cameron. —Mr. Reid Holmes, assistant superintendent of Duke Hospital, Durham, has been named administrator to succeed Mr. Ray E. Brown, who resigned to become assistant director of the University of Chicago Clinics. —Joseph E. Hawkins Jr., Ph.D., formerly instructor in physiology and special research associate in the psychoacoustic laboratory at Harvard Medical School, Boston, has joined the faculty of the Bowman Gray School of Medicine as assistant professor of physiology and pharmacology.

OHIO

Library Named for Woman Physician.—The medical library at Dunham Hospital, Cincinnati, has been named in honor of Dr. Vera V. Norton, who was associated with the hospital until her recent retirement. *Women in Medicine* reports that this library is one of the most valuable on the subject of tuberculosis.

New Chief of Industrial Hygiene Appointed.—Dr. Charles M. McGill, U. S. Public Health Service, has been named chief of the industrial hygiene division of the Ohio State Department of Health. He succeeds Dr. Christopher Leggo, who resigned several months ago. Dr. McGill graduated at Vanderbilt University School of Medicine, Nashville, Tenn., in 1935. He was commissioned in the U. S. Public Health Service in 1936 and subsequently served in various capacities throughout the country. In July 1945 he completed a postgraduate course at the Harvard School of Public Health, Boston, and received a degree of M.P.H. in industrial hygiene.

OKLAHOMA

Annual Clinical Conference.—The fifteenth annual clinical conference of the Oklahoma Clinical Society will be held at the Biltmore Hotel, Oklahoma City, November 26-29. The guest lecturers will be:

Dr. Lewis G. Allen, Kansas, Radiology.
Dr. Walter Putnam Blount, Milwaukee, Orthopedic Surgery.
Dr. Louis A. Brunsting, Rochester, Minn., Dermatology.
Dr. Richard B. Catell, Boston, Surgery.
Dr. Warren Henry Cole, Chicago, Surgery.
Dr. Virgil S. Counseller, Rochester, Minn., Surgery.
Dr. Charles Brenton Higgins, Chicago, Urology.
Dr. Ernest E. Irons, Chicago, Internal Medicine.
Dr. Raymond William McNeely, Chicago, Surgery.
Dr. Avery D. Prangen, Rochester, Minn., Ophthalmology.
Dr. Jean Paul Pratt, Detroit, Gynecology.
Dr. Chester A. Stewart, New Orleans, Pediatrics.
Dr. Charles Turner Stone, Galveston, Texas, Internal Medicine.
Dr. Theodore E. Walsh, St. Louis, Otolaryngology.
Dr. Frank E. Whitacre, Memphis, Tenn., Obstetrics.
Dr. Selon M. White, Minneapolis, Internal Medicine.

SOUTH CAROLINA

Annual Refresher Course.—The Medical College of the State of South Carolina, Charleston, will hold its annual refresher course October 31-November 2. Among the speakers will be:

Dr. Thaddeus L. Montgomery, Philadelphia, Bleeding in Obstetrics.
Dr. Richard Kovacs, New York, Physical Medicine and the General Practitioner.
Dr. Charles F. McKhann, Detroit, Advances in Pediatric Therapy.
Dr. Hal M. Davison, Atlanta, Ga., Allergy and General Medicine.
Dr. Walter C. Alvarez, Rochester, Minn., New Developments in Gastroenterology.
Dr. Robert B. McIver, Jacksonville, Florida, Abdominal Pain and Noncalculous Obstruction of the Upper Urinary Tract: Diagnosis and Surgical Management.
Dr. Eli Jefferson Browder, Brooklyn, Surgery for Pain.
Dr. Jean Verbrugge, Brussels, Belgium, Basic Principles of Fracture Surgery.
Dr. John S. Lockwood, New Haven, Conn., Recent Advances in Prevention and Treatment of Surgical Infection.

The program will include clinical case presentations and round table discussions. At the founder's day banquet at the Francis Marion Hotel, November 1, Dr. Alvarez will speak on the "Emergency of Modern Medicine from Ancient Folk-Ways."

TEXAS

Speakers' Bureau Formed to Combat Socialized Medicine.—The Texas State Medical Association has created a speakers' bureau, members of which will be available to give talks on socialized medicine to state lay organizations, civic clubs, P. T. A. groups, American Legion posts, chambers of commerce, women's clubs and other representative organizations. The members of the speakers bureau were chosen by the fifteen councilor districts of the state association.

Personal.—Chauncey D. Leake, Ph.D., vice president, University of Texas Medical Branch, Galveston, has been elected corresponding member of the Academy of Sciences of Lima. —Charles M. Pomerat, Ph.D., professor of anatomy, University of Texas Medical Branch, Galveston, has been elected an honorary member of the Academy of Sciences of Mexico. Dr. Pomerat recently spent six weeks in Mexico City as the guest of the academy and of the school of medicine to assist in the establishment of tissue culture laboratories.

Medical Foundation Campaigns for Funds.—Announcement of a campaign to raise a five year operating fund of \$1,300,000 for the Southwestern Medical Foundation, Dallas, has been received from Dr. Edward H. Cary, foundation president. A fund of \$1,000,000 is now held by the foundation for the building of the main plant of the Southwestern Medical College of the Southwestern Medical Foundation, which will be constructed adjacent to the new \$7,000,000 City-County Hospital as the nucleus of a new medical center in Dallas.

Child Health Council.—On August 12 the organization of the Texas Child Health Council was completed with the following members:

Dr. Frank H. Lancaster, Texas Pediatric Society.
Dr. John E. Ashby, Dallas, American Academy of Pediatrics.
Dr. Holman Taylor, Fort Worth, State Medical Association of Texas.
Dr. Fred P. Helm, Austin, Texas State Board of Health.
Dr. Thomas J. McElhenny, Austin, American Academy of Pediatrics, Texas Section.
Dr. James H. Park Jr., Houston, Baylor University, College of Medicine, Department of Pediatrics.
Dr. Hugh L. Moore, Dallas, Southwestern Medical College, Department of Pediatrics.
Chauncey D. Leake, Ph.D., Dean, University of Texas Medical Branch, Galveston.
F. Elliott, D.D.S., Houston, dean, University of Texas School of Dentistry.
Dr. Boyd Reading, University of Texas School of Medicine Department of Pediatrics.
Dr. George M. Decherd Jr., Galveston, director, Postgraduate Education, University of Texas Medical Branch.
Dr. Arild E. Hansen, Dallas, University of Texas child health program.

According to the *Texas State Journal of Medicine*, unable to be at the conference, but presumably considered a part of the personnel of the Council, were Dr. Cobb O. Terrell, Fort Worth, regent of the University of Texas, who was invited as a representative of pediatricians at large; Robert R. L. Sutherland, Ph.D., Austin, director, Hogg Foundation, and W. A. Buckner, D.D.S., Austin, dental consultant, Maternal and Child Health Division of the Texas State Board of Health. The functions of the Texas Child Health Council as set up at the first meeting are to:

Correlate, encourage and initiate activities which concern the medical and dental aspects of the child health problem in Texas, recognizing the essential and necessary leadership of physicians and dentists in these matters.

Integrate pediatric meetings and conferences and foster special ones. Stimulate investigative activities: clinical problems and fundamental research.

Aggressively cooperate in programs pertaining to child health carried on by professional, semiprofessional and lay groups, under the leadership of physicians and dentists.

Point out the present unsatisfactory status of hospital facilities for children in Texas and institute measures to improve these conditions. Cooperate with the state board of health in reducing child mortality and the high incidence of preventable children's diseases.

Assist in promoting more effective pediatric training programs for Texas pediatricians, general physicians and others concerned with child health.

WISCONSIN

Jackson Clinic Resumes Postgraduate Series.—With a special program September 29 the Jackson Clinic, Madison, resumed its postgraduate clinics, which had been held bimonthly the past twenty years until 1941.

State Medical Golfers Organize.—The Wisconsin State Medical Golfers' Association has been organized with Drs. George R. Love, Oconomowoc, the first president, Joseph C. Griffith, Milwaukee, vice president, and Ernest W. Miller, Milwaukee, secretary-treasurer. The first tournament was held at the Ozaukee Country Club, August 30.

Ira Thompson Honored.—The Racine County Medical Society gave a dinner at the Meadowbrook Country Club, Racine, September 20, in honor of Dr. Ira F. Thompson, who is retiring as health officer of Racine (*THE JOURNAL*, June 30, p. 678). The speakers at the dinner included Drs. Carl N. Neupert, Madison, state health officer; William T. Clark, Janesville; Albert E. Rector, Appleton; Stephen E. Gavin, Fond du Lac; George W. Walter, Racine, president of the county medical society; T. Charles Hemmingsen, Russell M. Kurten, all of Racine, and W. W. Bauer, formerly health officer of Racine and now director of the Bureau of Health

Education of the American Medical Association. Dr. Thompson, who was presented with a gold mounted pen and pencil set, will continue as vice president of the state board of health. He is retiring to a farm near Beloit.

GENERAL

Edwin MacEwan Named to New Position with Cancer Society.—Mr. Edwin J. MacEwan has resigned as executive vice president of the chamber of commerce of New Haven, Conn., to become administrative director of the American Cancer Society, effective October 1. The appointment is a newly created one.

Course in Endocrinology.—The American College of Physicians will sponsor a course in endocrinology at the Hotel Continental, Chicago, November 5-10. The course offers an opportunity for physicians to bring themselves up to date in the field of endocrinology. The faculty of fifty-two includes many leading endocrinologists from all over the United States and Canada. Numerous institutions are represented. Dr. Willard O. Thompson, Chicago, is director of the course.

Macy Foundation Receives Gift.—The Josiah Macy Jr. Foundation of New York will receive the residuary estate of Mrs. Kate Macy Ladd, Peapack-Gladstone, who died August 27, according to the *New York Times*, September 14. Another provision for the foundation is contained in a clause in her will creating a fund of \$2,500,000 and stipulating that the income shall be used to initiate, stimulate, develop and support scientific investigations of the fundamental aspects of health, sickness and relief of suffering.

Relation of Atomic Bomb to X-Rays.—Dr. Robert S. Stone, professor of roentgenology, University of California School of Medicine, San Francisco, will discuss the connection between x-rays and the atomic bomb at the memorial dinner in honor of Wilhelm Conrad Roentgen at the Palmer House, Chicago, November 8 under the auspices of the American College of Radiology, Chicago Medical Society, Chicago Roentgen Society, Institute of Medicine of Chicago and the Physics Club of Chicago. The dinner will be one of the features of the week designated "x-rays in health week of the American College of Radiology" (*THE JOURNAL*, October 6, p. 471).

The Salmon Lectures.—Dr. Roy Graham Hoskins, research associate in physiology, Harvard Medical School, Boston, Salmon memorial lecturer for 1945, will deliver his lecture series "The Biology of Schizophrenia" on the three successive Friday evenings of November 2-16 at the Academy of Medicine, 2 East 103d Street, New York (*THE JOURNAL*, March 3, 1945, p. 535). Of the three lectures, the first will be "Biology of Man in Relation to Schizophrenia," the second "The Pattern of Schizophrenia" and the third "The Biological Appraisal of Schizophrenia." The lectures are sponsored by the Salmon Committee on Psychiatry and Mental Hygiene, 200 Retreat Avenue, Hartford 2, Connecticut.

Annual Report of Nutrition Foundation.—The Nutrition Foundation, New York, has just released its annual report for the year ended June 30, 1945. The foundation, since 1942, has allocated \$921,190 for fundamental research in the science of nutrition, covering the following six areas of activity: research directed toward discovering and measuring the human requirements for each of the forty or more essential nutrients, how each nutrient functions in the body, nutritive requirements for infants and mothers, relationships between nutrition and health, education to facilitate the application of new and sound information and projects undertaken chiefly as a direct contribution toward winning the war. The report discusses the various research projects carried out under the auspices of the foundation and may be obtained from the foundation offices in the Chrysler Building, New York 17.

Expansion of Winthrop Research Laboratories.—The Winthrop Chemical Company has announced the purchase of a 60 acre site at Rensselaer, N. Y., where new research laboratories will be constructed at a cost of more than two million dollars. According to Dr. Theodore G. Klumpp, New York, president of the company, the new structure will be situated close to the present plant and laboratory facilities and will replace the existing research laboratories. In addition, Sterling Drug, of which Winthrop is a subsidiary, will utilize the new laboratories to supplement research of its other units. Construction is expected to start next spring and to be completed within a year. In addition to offices, the administrative wing will have space for an 80,000 volume technical library. The biologic wing will contain twenty-five laboratory

units, together with rooms for photography, x-ray and extreme temperature testing. The chemistry wing will have thirty-two laboratory units as well as special chemical and development facilities and a pilot development plant.

Research Fellowships in Medicine.—The American College of Physicians announces the resumption of its research fellowships in medicine, which were discontinued during the war. These fellowships, limited in number, are designed to provide an opportunity for research training either in the basic medical sciences or in the application of these sciences to clinical investigation. They are for the benefit of physicians who are in the early stages of their preparation for a teaching and investigative career in internal medicine. Assurance must be provided that the applicant will be acceptable in the laboratory in which he has chosen to work and that the laboratory will supply the facilities necessary for the proper pursuit of the research. The term of appointment is for one year. The fellowship stipend will be from \$1,800 to \$2,500 per annum. Application forms for 1946 fellowships will be supplied on request to the American College of Physicians, 4200 Pine Street, Philadelphia 4, and must be submitted in duplicate not later than November 1. Awards will be made on or about November 18. Dr. Francis G. Blake, New Haven, Conn., is chairman of the committee on fellowships and awards.

Course in Allergy.—The American College of Allergists announces an instructional course at Thorne Hall, Northwestern University, Chicago, November 5-10. The course is free to all those serving in the armed forces. Among the speakers will be:

- Dr. Paul R. Cannon, Chicago, Experimental Allergy.
- Dr. Carl Draystedt, Chicago, Maternal Medicine of Allergy and Pharmacology of Drugs Used in Allergy.
- Dr. Albert D. Rudmann, Cleveland, Ocular Allergy.
- Dr. Andrew C. Ivy, Chicago, Reaction from Blood Transfusion.
- Dr. Alvin L. Barach, New York, Inhalation Therapy of Bronchial Asthma.
- Dr. Foster Kennedy, New York and Bayard T. Horton, Rochester, Minn., Allergy of the Central Nervous System—Migraine and Meniere's Disease.
- Dr. John Warlick Thomas, Richmond, Va., Allergic Bronchitis, Bronchiectasis.
- Dr. Theron G. Randolph, Chicago, Miscellaneous Allergies—Agranulocytosis.

At an informal dinner Monday, the first day, William H. Welker, Ph.D., will speak on "Antigenicity of Proteins in Relation to Allergy."

Changes in Status of Licensure.—The Massachusetts Board of Registration in Medicine on July 30 restored the license to practice medicine of Dr. Herbert N. duGerardell, East Boston. The Alabama State Board of Medical Examiners on August 6 revoked the license of Dr. James Franklin Johantgen, Talladega, Ala. (*THE JOURNAL*, July 21, p. 894). The California State Board of Medical Examiners recently took the following actions:

- Dr. Ferdinand M. Ferguson, North Hollywood, license revoked.
- Dr. Milton Francis Novotny, Long Beach, license revoked.
- Dr. Courtland R. Sanborn, Oakland, license revoked.
- Dr. Ben Smith, Los Angeles, license revoked.
- Dr. Roy Reginald Lessing Sturges, Los Angeles, license revoked.

The New York State Board of Medical Examiners announces that the license of Dr. Abraham Gillman, New York, has been reinstated. The New York board also recently took the following actions:

- Dr. Louis Stanley Barnett, New York, license revoked.
- Dr. Anthony A. Flaudina, New York, license revoked.
- Dr. Samuel Shauer, Brooklyn, license suspended for six months.
- Dr. Raymond J. Stockhammer, New York, license revoked.

The Michigan Board of Registration in Medicine on June 12 continued the suspension for one year of the license of Dr. Edward Harry Thomas, Detroit.

Health Council Urges "Pooling" of Resources.—Complete reorganization of the nation's 20,000 voluntary health agencies under a "strong, central agency" and the pooling of their fund-raising appeals on a countrywide basis were urged in a report made public September 16 by the National Health Council, an affiliation of eighteen health agencies. According to the *New York Times*, giving the voluntary agencies credit for much of the progress in public health, the report "Voluntary Health Agencies—An Interpretative Study," by Selskar M. Gunn, C.P.H., and Philip S. Platt, Ph.D., was compiled under a grant from the Rockefeller Foundation. It involved field work and research for three years and studied 568 agencies in sixty-five cities and twenty-nine states. It was stated that independent and uncoordinated attacks on specific diseases without central or unified planning often had resulted in con-

fusing the public as to the goals of individual and public health. It was believed that the expansion of the National Health Council with a dynamic program and effective field services to function on request for member organizations throughout the country would remedy this situation. The report recommends that the present separate money-raising appeals be coordinated in a nationwide campaign, while the two agencies with specially effective money-raising devices, the tuberculosis and infantile paralysis groups, were urged to broaden their fields of interest and service. The overall plan put forward in the report advocated the preparation of a single combined health agency budget for every city, town and village, using a technic similar to that of the National War Fund.

LATIN AMERICA

Personal.—Col. George M. Powell, M. C., is the new assistant chief health officer of the Panama Canal, succeeding Col. Albert R. Dreisbach, M. C., whose reassignment in June terminated a seven month tour of duty on the Isthmus.—Dr. Gonzalo Estrada de la Riva, Havana, Cuba, has been appointed professor of allergy for an extension course at the University of Havana. According to the *Annals of Allergy* although these postgraduate courses have been held the past four years, this is the first time that allergy has been included.—Major Harold Jackson Davis, M. C., has been named chief of the field party in Uruguay of the Servicio Cooperativo Inter-Americano de Salud Publica.

Guggenheim Fellowships.—Included among recent Latin American fellowships awarded by the John Simon Guggenheim Memorial Foundation for advanced study in the United States are the following in medicine:

- Dr. Jose Jesus Estable, subdirector, Institute for Experimental Medicine, Montevideo, Uruguay, studies in the field of experimental pharmacology, particularly the pharmacodynamics of emetine.
- Dr. Alfonso Graña, investigator, Institute for Experimental Medicine, Montevideo, Uruguay, studies in the field of immunology. Dr. Graña will work at the Mayo Foundation, Rochester, Minn., with Hiram L. Essex, Ph.D.
- Dr. Eduardo Aguirre Pequeno, director, Institute of Scientific Research, University of Nuevo Leon, Monterrey, N. L., Mexico, studies in the field of medical parasitology. He will work at Tulane University, New Orleans, with Ernest C. Faust.

CORRECTION

Hypoprothrombinemic Action of Quinine Sulfate.—In the article by Pink and Engelberg in *THE JOURNAL*, August 11, references 8 and 9 as printed lead to a misrepresentation. The prothrombinopenic action of the salicylates was established by the workers cited under 8 and 9, but the protective effect of vitamin K against such hypoprothrombinemia has been demonstrated only by the authors cited under 8, with the exception of Rapoport, Wing and Guest.

Government Services

Leon Gardner to Head Medical Library

Col. Leon L. Gardner, formerly in charge of public relations and military intelligence at the Surgeon General's Office, has been appointed director of the Army Medical Library by Surg. Gen. Norman T. Kirk. Col. Harold W. Jones, director of the library, will be retired from active duty January 1. He is now on terminal leave. Colonel Jones reached the statutory retirement age in November 1941 but was requested by the Surgeon General to remain on wartime duty as librarian of the Army Medical Library. He held this position until a year ago, when he took over the newly created office of the director. Colonel Gardner, former director of the Bureau of Army Affairs of the American Red Cross, graduated at the top of his class at the Army Medical School in 1924 and again at the Medical Field Service School at Carlisle, Pa., in 1925. He was awarded the Hoff medal and the Shimmer medal for his scholastic standing at each of those schools. In 1937 he qualified for service on the war department general staff by becoming a graduate of the Command and General Staff School at Fort Leavenworth, Kansas. Colonel Jones graduated at Harvard Medical School, Boston, in 1901. He was an honor graduate from the Army Medical School in 1906 and graduated from the Army Medical Field Service School in 1930.

Synthetic Estrogens in Malignant Disease

Prof. E. C. Dodds, who discovered the synthetic estrogen diethylstilbestrol, has reviewed the present status of synthetic estrogens in malignant disease in the *West London Medical Journal*. The fact that the female sex hormone responsible for secondary sexual characteristics can exist in three forms—estrone, estriol and estradiol—suggested to him the possibility of producing estrogens synthetically. These could be given by mouth. The first evidence that estrogens might influence the course of malignant disease was produced by Kaufmann in 1935, when he showed the beneficial effect of natural estrogens on kraurosis vulvae. This effect on a precancerous condition is perhaps the first indication of the value of these estrogens in malignant disease. But it is in carcinoma of the prostate that the greatest interest in these substances has recently been shown. Nearly fifty years ago castration for the relief of symptoms of carcinoma of the prostate was widely advocated. In many cases the primary growth and the metastases decreased. The operation naturally was objectionable, and interest in the subject died down until revived by the work of the American surgeon Charles Huggins. The British genito-urinary surgeon E. W. Riches stated at a joint meeting of the Pathological Society and the Biochemical Society that in his experience almost 95 per cent of the cases of carcinoma of the prostate respond to estrogens.

Professor Dodds considers that the mode of action of estrogens is obscure. The action may be on the pituitary by inhibiting the secretion of the gonadotropic hormone of the anterior lobe, it may be on the testes by suppressing the secretion of testosterone or it may be directly on the malignant growth itself. Of these hypotheses Dodds finds the first most attractive to the experimental biologist, but it is claimed that the effect of synthetic estrogen is superior to castration. This would indicate that suppression of the function of the anterior lobe of the pituitary is not the sole explanation. While the relief of symptoms occurs, cure cannot be claimed. But it must be remembered that diethylstilbestrol is the first substance ever produced that has an action of any sort on cancer when administered by mouth. The success in carcinoma of the prostate has led to the use of estrogens in every variety of carcinoma. In carcinoma of the breast beneficial effects have been obtained in only a small percentage of cases. Those recorded varied from slight relief to complete disappearance of the tumor and metastases. It is not known what type of case will respond or whether the effect is permanent.

Failure of Pertussis Vaccine

A. M. McFarlan, Elizabeth Topley and Mary Fisher in the *British Medical Journal*, August 18, report a trial of whooping cough virus carried out by the health department at Oxford under the direction of the Medical Research Council. Over 600 susceptible children from 6 months to 3 years of age attending welfare clinics and wartime day nurseries were divided into "inoculated" and "control" groups by methods designed to render the groups similar in every respect except for the inoculation. The inoculated children were given either two doses of pertussis vaccine at a four week interval or four doses at intervals of one, one and four weeks. The total dosage ranged from 40,000 to 100,000 million organisms; corresponding to an American dosage of 120,000 to 300,000 millions. Whooping cough occurred sporadically in Oxford during the

succeeding eighteen months. No significant difference was observed in the incidence or severity of whooping cough between the inoculated and the control children. Of 327 inoculated children 12.5 per cent and of 305 control 14.1 per cent developed definite whooping cough. The conclusion is that the investigation lends no support to the view that pertussis vaccine is of value in the prophylaxis of whooping cough, and it is suggested that its use should be discontinued till some positive evidence of its value is obtained in further carefully controlled trials. The vaccine used was prepared by Burroughs Wellcome & Co. Since the possibility could not be excluded that this vaccine differed in some material way from vaccines prepared in the United States and Canada, it is proposed to carry out another investigation with an American vaccine. This is now being undertaken with a vaccine manufactured by Parke, Davis & Co. of Detroit according to the method of Dr. Sauer of Evanston, Ill.

ICELAND

(From Our Regular Correspondent)

REYKJAVIK, Sept. 14, 1945.

Mass Radiography in the Early Detection of Pulmonary Tuberculosis

Last winter the inhabitants of Reykjavik underwent a mass examination with miniature radiography to detect tuberculosis. These examinations were made by the staff of the tuberculosis center of the capital under personal direction of Dr. S. Sigurdsson, head of the nation's campaign against tuberculosis. A total of 43,196 people were examined, or 94.2 per cent of the inhabitants. As all children under 1 year of age were omitted, being otherwise controlled, practically everybody who was not prevented by total infirmity, sickness or absence showed up voluntarily at the examination. Actually 99.6 per cent of people who could reasonably be expected to present themselves were examined. The examinations lasted four months, starting in the middle of January and being finished on the 19th of May. Of the total number 986 were requested to return for further examination. The reason for these requests was either that the pictures were technically imperfect or they were suggestive of disease.

RESULTS

Of the total number 25, or 0.5 per thousand, were found to have contagious tuberculosis. These persons were of all ages and their disease advanced to various degrees. None of them were cognizant of the disease before. Most of these people were sent to sanatoriums without delay. Another 25, or 0.5 per thousand, were found to suffer from active tuberculosis without having bacilli in the sputum. A further group, 14, or 0.3 per thousand, had pulmonary tuberculosis in a stage which required strict supervision. The total number of tuberculous patients found amounts therefore to 64, or 1.4 per thousand of the examined. Only 8 of these patients were known to the center before.

When compared with the findings of a similar investigation in London recently (*THE JOURNAL*, July 14, p. 822) it will be seen that the number of affected individuals found is almost ten times lower in Reykjavik than in London, where between 1 and 1.5 per cent of fresh cases were discovered. The explanation for this difference may be the previous activity of the tuberculosis center in Reykjavik, which has been searching efficiently for tuberculosis in a small town where conditions are more evident than in the great metropolis.

In spite of the few fresh cases found, the result is considered satisfactory. After all, 25 carriers, each of whom may be expected to transmit the disease to a number of other people, are by no means a negligible danger to the community, which can better afford the public expense than the danger which the ignorance of infection implies.

BRAZIL

(From Our Regular Correspondent)

SÃO PAULO, July 30, 1945.

The Transantral Route in Surgery of the Accessory Nasal Sinuses

Professor Erniro Lima has pointed out the benefits of the transantral route in surgery of the accessory nasal sinuses. The ethmoid is the genetic and anatomic center of the paranasal cavities; as such it acts as an evolutive pathologic center and is thus responsible, by origin or maintenance, for acute and chronic infectious states of the other sinuses. Polysinusitis is usually found in inflammatory states of the facial sinuses; the ethmoidofrontomaxillary association is the most common and sphenoiditis comes next, also commonly associated with posterior ethmoiditis. The role of the mucosa as a continuous intercavity element in the propagation of the infection should not be forgotten. Even though the inflammations of the sphenoidal and maxillary sinuses might originate from rhinopharyngeal or dental infections, the concomitant or subsequent inflammations of the labyrinth of the ethmoid represent the main factor in the maintenance of sphenoiditis or maxillitis.

According to Professor Erniro Lima's practice, certain procedures are now established in the transmaxillary method: (a) A small opening in the anterior wall of the maxillary sinus is sufficient to reach the intraethmoid and to maneuver inside it. (b) The complete destruction of the cells and other projections or bony laminae of the inferior angle of the ethmoid (between the lamina papyracea and the superior wall of the maxillary sinus) is indispensable. (c) The opening which allows the penetration in the ethmoid (in the superior internal angle of the maxillary sinus) should be made at the expense of the inferior ethmoid angle and never by sacrificing the nasal wall. (d) Penetrating the ethmoid, one should go toward the superior ethmoid angle (between the superior wall of the ethmoid and the orbital wall), where the roof of the ethmoid offers great resistance and where the cells with supraorbital prolongations can be found. (e) The route of the curet from the maxillary cavity to the upper wall of the ethmoid should describe from the bottom up the form of a Z; that is to say, to the upper wall of the sinus, to the inferior angle of the ethmoid, to the lamina papyracea, to the upper angle of the ethmoid and to the upper wall of the ethmoid. (f) The route of the curet anteroposteriorly should describe the shape of an elongated S; that is to say, (1) starting from the middle part of the ethmoid toward the front the curet bends toward the anterior wall of the front and outward, destroying the cells and the frontal bullae in the lateral region of the floor of the sinus; (2) starting again from the middle region of the ethmoid toward the sphenoid in the proximity of the anterior wall of the latter, it must turn inside as it penetrates the cavity. (g) The regions of the meatus medius and the concha, as important functional and morphologic elements, should be left intact. (h) The maxillary counteropening is necessary especially for postoperative drainage, leaving free the region of the meatus medius.

The transmaxillary method prevents altogether any morphologic and functional harm to the fossa nasalis. Furthermore, it avoids a mutilative operation which might have serious sensory and psychologic repercussions, which cannot be underestimated.

Psychiatric Hospital Care in São Paulo

São Paulo, with a population of more than 8 million, is putting into practice a plan of improvement of its psychiatric hospital service. The state government is building new hospitals and enlarging others in order to be able to transfer to good institutions patients who are not now receiving the proper psychiatric care. Dr. Edgard Pinto Cesar, director of the psychiatric service of the state of São Paulo, points out that the measures undertaken by the state will make it possible to

give proper care to mental patients who otherwise would miss the specialized medical treatment during the most favorable phase of the illness. Data of the Juquary Psychiatric State Hospital reveal that up to 75 per cent of the patients show decided improvement if treated in the early stages. Only 10 per cent of cases given treatment in the late stages show improvement. Dr. Pinto Cesar hopes that by next October it will be possible to hospitalize all mental cases in the state. Two new psychiatric hospitals and a new wing in the Juquary Hospital will add 1,500 beds: 300 in Juquary, 600 in the St. Theresa Hospital at Ribeirão Preto and 600 in the Pinel Hospital of the city of São Paulo. The plan provides for 1,000 more beds to become available in the course of 1946.

Personal

Dr. Orestes Rossetto, associate professor of physiology at the University of São Paulo, has been appointed professor ad interim to substitute for Dr. C. Moura Campos, who left for the United States to visit several medical institutions.

Dr. Edmundo de Vasconcellos, professor of surgery at the University of São Paulo, is now in the United States as a fellow of the Blaire House of Washington, D. C. Dr. Vasconcellos is the originator of special technique for the surgical treatment of cancer of the larynx and the esophagus and the author of several textbooks on surgery well known in Brazil. His book on modern methods of amputations has been published in English.

To Lieut. Col. Benjamin Gonçalves, assistant to the surgeon general of the Brazilian army, has been awarded the medal of Military Merit for special and valuable services.

Dr. Jorge S. Marsillac of the division of cancer of the National Department of Health and a practitioner of cancerology at Rio de Janeiro, has just arrived from the United States, where he was occupied for sixteen months as a fellow of the Memorial Hospital, New York.

Marriages

CHARLES MATTHEWS STRATEMAN, White Plains, N. Y., to Lieut. Ingrid Helen Leire of New York in Eibach, Germany, July 23.

FRANCIS RITTENHOUSE SOUDER, Souderton, Pa., to Miss Marian Rita Parker of Pen Argyl in Philadelphia recently.

LEON LOUIS BERNIS, Philadelphia, to First Lieut. Mildred Vivian Groh of Wilkes-Barre, Pa., August 19.

MAX BAUMEISTER JR., Norfolk, Va., to Miss Nancy Lydia Makovsky of Prince George, September 1.

JOHN EDWARD FLYNN, Tryon, N. C., to Miss Anne Frances Redmond of New York, September 1.

LEON WALLACE to Miss Fern Barbara Wixen, both of Los Angeles, in New York, September 14.

HOWARD A. SPINDLER, Rochester, N. Y., to Miss Barbara Hayes Smith of Sheds, August 24.

EDWARD T. EDWARDS JR. to Miss Mary Jane Decker, both of Vincennes, Ind., June 30.

JAY DURAND, Seattle, to Mrs. Gertrude Huntley Green of Vancouver, B. C., recently.

ELI N. BERNSTEIN, Detroit, to Lieut. Marjorie O. Boyd in Oxford, England, May 2.

BRANCH CRAIG JR., El Paso, Texas, to Miss Jean McCracken of Joliet, Ill., August 18.

MILTON ERNEST BAKER, Minneapolis, to Miss Ilene Godfrey of St. Paul, August 13.

FRANK STUART RYLBSON, Detroit, to Miss Ann LeClear in Chicago, August 7.

ISRAEL H. LAVINE, Melrose, Wis., to Miss Harriet Rosen of Sparta recently.

PAUL THORPE LOWRY, Price, Utah, to Miss Jeanette Kraemer recently.

Deaths

Smith Ely Jelliffe ♂ noted psychiatrist, died September 25 at his summer home near Hulets Landing, Lake George, N. Y. Dr. Jelliffe was born in New York Oct. 27, 1866. He graduated at the Columbia University College of Physicians and Surgeons, New York, in 1889, subsequently receiving his Ph.D. and A.M. degrees. He served an internship at St. Mary's Hospital, Brooklyn.

In 1896, while at the Binghamton State Hospital, he met Dr. William A. White and thus began a long professional friendship. In addition to conducting a large private practice, Dr. Jelliffe was clinical professor of mental diseases at Fordham University from 1907 to 1912; instructor in materia medica and therapeutics from 1903 to 1907 and professor of pharmacognosy and technical microscopy from 1897 to 1907 at the Columbia University College of Pharmacy, and adjunct professor of diseases of the mental and nervous system at the Post-Graduate Medical School and Hospital from 1911 to 1917. He was visiting neurologist at the City Hospital from 1903 to 1913 and at the time of his death was consulting neurologist at the Manhattan State and Kings Park hospitals.

He held membership in numerous societies, including the American Psychiatric Association, Philadelphia Neurological Society and the New York Academy of Medicine. He had been vice president and president of the American Neurological Association; he also had been president of the New York Neurological Society, American Psychopathological Association and the American Psycho-Analytic Society. He was an Affiliate Fellow of the American Medical Association and a specialist certified by the American Board of Psychiatry and Neurology, Inc. In addition he was a member of many foreign groups.

A man of prodigious energy, Dr. Jelliffe's career included many activities. He was a prolific writer of medical articles and the author of a number of textbooks. In 1938 a celebration was held to observe his thirty-fifth anniversary as editor of the *Journal of Nervous and Mental Disease*, a position which he held until recently. From 1913 until recently he held a similar position with the *Psychoanalytic Review*. He and Dr. White formerly edited the *Nervous and Mental Monograph Series*. In 1941 Dr. Jelliffe gave his library of fifteen thousand volumes and more than twenty-five thousand reprints on nervous and mental diseases to the Neuro-Psychiatric Institute of Hartford Retreat, Hartford. The collection was said to be one of the most complete in the world. He was editor of the *Medical News* in New York from 1900 to 1905 and associate editor of the *New York Medical Journal* from 1905 to 1909.

His versatility, his genius as a writer and teacher and his dynamic character combined to give him a position of leadership in each of the many fields to which he devoted his efforts.

Isidore Friesner ♂ Katonah, N. Y.; Gross Medical College, Denver, 1901; served as president and secretary of the American Otolological Society; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological, Rhinological and Otolological Society; fellow of the American College of Surgeons; joined the medical staff of the Mount Sinai Hospital, New York, in 1920 and became otologist to the hospital a year later; president of the medical board from 1927 to 1938; under his direction of the department of otology, the training of residents in this field was started at the hospital; one of the first to recognize the importance of microscopic studies in diseases of the ear and responsible for the establishment at the hospital of a histopathologic department and laboratory facilities in connection with otology in 1928; on April 27, 1944 a portrait of him was presented to the hospital in commemoration of his seventieth birthday and as a tribute to his twenty-four years of service at Mount Sinai and to his pioneering work in establishing the relation of otology to general medicine; associated with the Bronx and Beth David hospitals in New York, Beth Moses and Methodist hospitals in Brooklyn, St. Joseph's Hospital in Far Rockaway and the Flushing (N. Y.) Hospital; specialist certified by the American Board of Otolaryngology; co-author of "Labyrinth" and "Cerebellar Abcess"; died September 8, aged 71, of coronary thrombosis.

William Avery Groat ♂ Syracuse, N. Y.; Syracuse University College of Medicine, 1900; member of the House of Delegates of the American Medical Association in 1939, 1940 and 1942; member of the American Association of Immunologists, American Association for the Study of Goiter, American Society of Clinical Pathologists and the Association for the Study of Internal Secretions; past president of the Medical Society of the State of New York and its fifth district branch;

at one time president of the Syracuse Academy of Medicine; fellow of the American College of Physicians; specialist certified by the American Board of Internal Medicine; served as professor of clinical pathology and medical jurisprudence at his alma mater, where he had been a trustee of the university and a member of its advisory board on athletics; served during World War I; lieutenant colonel, Medical Officers Reserve Corps, at the time of his death; had been associated with the City Hospital, Syracuse Memorial Hospital, St. Joseph Hospital and Hospital of the Good Shepherd; served as chairman of the advisory committee of the city health department; member of the management committee of the *New York State Journal of Medicine*; died September 9, aged 68, of chronic myocarditis and cerebral arteriosclerosis.

Charles Gilmore Kerley ♂ New York; University of the City of New York Medical Department, 1888; for many years professor of pediatrics and later emeritus at the New York Polyclinic Medical School and Hospital; specialist certified by the American Board of Pediatrics, Inc.; member and past president of the American Pediatric Society and the New York County Medical Society; fellow of the New York Academy of Medicine; member of the American Academy of Pediatrics; consulting pediatrician to Babies' Hospital and Hospital for Joint Diseases in New York, St. John's Hospital in Yonkers, Tarrytown (N. Y.) Hospital, Methodist Hospital in Brooklyn, Greenwich (Conn.) Hospital, Vassar Hospital, Poughkeepsie, N. Y., Fitkin Memorial Hospital, Neptune, N. J., Wassaic (N. Y.) State School, Mary McClellan Hospital, Cambridge, N. Y., and the Sharon (Conn.) Hospital; author of "Short Talks with Young Mothers," 1902, 1910, 1916 and 1925; "Practice of Pediatrics," 1914, 1918 and 1924; "Treatment of Diseases of Children," 1907 and 1909; "What Every Mother Should Know," 1915; "Digestive Disturbances in Infants and Children," 1924, and a novel, "Where is My Mother," in 1933; died September 7, aged 82, of heart disease.

Kenneth Clark Strong, Los Angeles; Stanford University School of Medicine, San Francisco, 1932; member of the American Medical Association and the American Society of Clinical Pathologists; diplomate of the National Board of Medical Examiners; specialist certified by the American Board of Pathology, Inc.; interned at the San Francisco Hospital; served as resident physician at the Presbyterian Hospital and Shoen Hospital for Women in New York; at one time on the faculties of Columbia University in New York and the Long Island College of Medicine in Brooklyn; served as director of laboratories at St. Francis Hospital in San Francisco and as consulting pathologist for the Veterans Administration facility; formerly affiliated with the division of laboratories and research, New York State Department of Health in Albany; began active duty as a major in the medical corps, Army of the United States, on Sept. 15, 1942 and service terminated January 1944 for physical disqualification; died July 3, aged 41, of heart disease.

George Rubin, Chicago; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; member of the American Medical Association; formerly fellow in pathology at Rush Medical College, University of Chicago; served as medicolegal counsel for the corporation counsel's office in the city of Chicago; attending physician on the medical staff of the Jewish Old People's Home, North Chicago Hospital, Michael Reese Dispensary, Mount Sinai Hospital and the Chicago Tuberculosis Institute; a captain in the medical corps of the U. S. Army during World War I; captain, medical reserve corps, U. S. Army, not on active duty; delegate to the International Medical Congress in Paris in 1900; died in the Michael Reese Hospital July 15, aged 68, of carcinoma of the liver.

George Edwin McPherson ♂ Amherst, Mass.; Baltimore Medical College, 1904; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association and the American Association on Mental Deficiency; member and formerly vice president of the New England Society of Psychiatry; served during World War I; lieutenant colonel, medical reserve corps, U. S. Army, not on active duty; assistant superintendent of the Foxboro State Hospital, Foxboro, 1914-1915 and the Medfield State Hospital in Medfield from 1916 to 1921; assistant executive officer, Boston Psychopathic Hospital, 1915-1916; for many years superintendent of the Belchertown State Hospital in Belchertown; died June 16, aged 68, of coronary thrombosis.

Elizabeth Leiper Martin, Blairstown, N. J.; Western Pennsylvania Medical College, Pittsburgh, 1902; member of the American Psychiatric Association; at one time physician on the staff of the Margaret Morrison College of the Carnegie

Institute of Technology and during the same period had charge of women at the University of Pittsburgh; interned at the Western Pennsylvania Hospital in Pittsburgh; served as resident physician at the Friends Hospital in Philadelphia and later took a similar position at Butler Hospital in Providence, R. I.; served as head of the mental hygiene service at Wellesley College and Pembroke College in Brown University; died in the Newton Memorial Hospital, Newton, September 8, aged 73, of generalized arteriosclerosis, and myocardial degeneration.

Toliver Moore McDuffee ☉ Manatee, Fla.; University of Tennessee Medical Department, Nashville, 1899; past president of the Florida Medical Association, the Florida Railway Surgeons Association and the Manatee County Medical Society; served as the medical member of the county draft board during World War I; twice mayor of Manatee; from 1917 to 1925 chairman of the county school board, which about a year ago named the Manatee Junior High School the McDuffee School as a mark of honor for his public services; for many years surgeon for the Seaboard Air Line Railway; county physician; died June 15, aged 79, of Parkinson's disease.

Andrew Benjamin Albritton, Wildwood, Fla.; University of Georgia Medical Department, Augusta, 1912; member of the American Medical Association; died May 3, aged 62, of cardiovascular disease and diabetes mellitus.

Harry Lewis Aldrich ☉ Caney, Kan.; Hering Medical College, Chicago, 1902; vice president, past president and for many years member of the state board of health; in 1915 state representative; for many years health officer; served as councilman and mayor of Caney; in recognition of his many years of service as a member of the state board of health was presented with a plaque by the board; died in the Washington County Memorial Hospital, Bartlesville, Okla., June 29, aged 76, of myocarditis.

Chester Arthur Ayres, Lorimor, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; member of the American Medical Association; served as secretary of the Polk County Medical Society and the Seventh District Medical Society; at one time on the faculty of the Drake University College of Medicine in Des Moines; died in Centerville June 29, aged 64, of coronary thrombosis.

John Peter Boroszewski ☉ Buffalo; University of Buffalo School of Medicine, 1926; died in the Buffalo General Hospital June 22, aged 44, of toxic hepatitis.

Charles Alonzo Brown, Plymouth, Ind.; Homeopathic Medical College of Missouri, St. Louis, 1890; died June 18, aged 83, of coronary occlusion.

John F. Burkhalter, Claxton, Ga.; University of Georgia Medical Department, Augusta, 1911; served during World War I; died in Savannah May 6, aged 59, of coronary thrombosis.

Manning Skinner Daniels, Pomeroy, Ohio; Western Reserve University School of Medicine, Cleveland, 1925; member of the American Medical Association; died June 13, aged 46, of coronary thrombosis.

Charles G. Elmore, Omaha; University of Tennessee Medical Department, Nashville, 1888; for many years surgeon for the Chicago and Northwestern Railroad; died in St. Joseph Hospital May 31, aged 87, of prostatic hypertrophy.

Alice Lucretia Ernst, Clifton Springs, N. Y.; Woman's Medical College of Pennsylvania, Philadelphia, 1888; formerly a missionary in India; died June 20, aged 84, of carcinoma of the gallbladder.

William Floyd Etter, Rogers, Texas; College of Physicians and Surgeons, Baltimore, 1892; member of the American Medical Association; local surgeon for the Santa Fe Railroad; city health officer of Rogers; died May 14, aged 77, of pneumonia following a cerebral hemorrhage.

Alfred Abraham Euster ☉ Philadelphia; University of Pennsylvania School of Medicine, Philadelphia, 1924; served on the staffs of the Jewish, Nazareth and Frankford hospitals; died in the Dufur Hospital, Ambler, May 20, aged 45.

Loren Ervin Grimes, Zanesville, Ohio; Starling-Ohio Medical College, Columbus, 1914; member of the American Medical Association; served as secretary-treasurer and vice president of the Muskingum County Academy of Medicine; on the staffs of the Good Samaritan and Bethesda hospitals; served as county coroner; died June 7, aged 57, of heart disease.

Daniel George Hersh, Lititz, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1886; died in the United Zion Home, Warwick Township, May 20, aged 79, of general arteriosclerosis.

Henry William Heuermann ☉ St. Louis; St. Louis University School of Medicine, 1904; on the staffs of the Lutheran and Alexian Brothers' hospitals; died June 29, aged 64, of cerebral hemorrhage.

William T. Hinton, Dacula, Ga.; Atlanta Medical College, 1894; member of the American Medical Association; died in the Emory University Hospital, Atlanta, May 10, aged 75, of arteriosclerosis.

William M. Holmes, Marionville, Mo.; St. Louis College of Physicians and Surgeons, 1893; member of the American Medical Association; died in Burbank, Calif., June 28, aged 82, of medullary depression, toxemia due to thrombus of abdominal aortic infarction and arteriosclerosis.

Claude Perry Jones, Detroit; Harvard Medical School, Boston, 1893; Boston University School of Medicine, 1905; served during World War I; formerly superintendent of the Ford Republic School for Boys in Farmington, Mich.; died in the Grace Hospital June 27, aged 75, of bronchopneumonia.

John Scott Kelso, Avalon, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1896; school physician; affiliated with the Suburban General Hospital in Bellevue, of which he had been one of the founders; died June 26, aged 79, of coronary occlusion.

Horace Louis Leiter, Cazenovia, N. Y.; Columbia University College of Physicians and Surgeons, New York, 1903; member of the American Urological Association; for many years on the staff of the University Hospital in Syracuse; died in Boston June 21, aged 67, of carcinoma of the cecum with metastases.

Lester Winslow Lord, West Ossipee, N. H.; Baltimore Medical College, 1897; veteran of the Spanish-American War and World War I; died in Winter Park, Fla., June 23, aged 70, of cerebral hemorrhage and hypertension.

William Lyon Lowrie ☉ Tyrone, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1883; served on the staffs of the Altoona and Mercy hospitals in Altoona and the Philipsburg (Pa.) State Hospital; died May 21, aged 85, of arteriosclerosis.

William Read Martin, Charlotte C. H., Va.; University College of Medicine, Richmond, 1907; member of the American Medical Association; past president of the South Piedmont Medical Society; past president and secretary of the Charlotte County Medical Society; county health officer; since 1937 president of the Charlotte County Library Board; died in the University Hospital, Charlottesville, June 24, aged 62.

Irving E. Ozanne ☉ Neenah, Wis.; Dunham Medical College, Chicago, 1899; on the staff of the Theda Clark Memorial Hospital; died in the Wisconsin General Hospital, Madison, July 12, aged 79, of ruptured diverticulum.

William Harrison Powell, Sulphur, Okla.; Baylor University College of Medicine, Dallas, 1905; city physician of Sulphur for many years; died June 1, aged 72, of carcinoma of the gallbladder and liver.

John Edward Powers, Wilton, N. H.; University of Vermont College of Medicine, Burlington, 1922; member of the American Medical Association; served during World War I; on the staffs of St. Joseph's Hospital and the Memorial Hospital in Nashua, where he died July 16, aged 53, of cerebral hemorrhage.

Leighton P. Ravenscroft, Winfield, Kan. (licensed in Kansas in 1901); member of the American Medical Association; mayor of Winfield six times; died in the Newton Memorial Hospital June 12, aged 84, of chronic myocarditis.

David Robert Rodger, New York; College of Physicians and Surgeons, medical department of Columbia College, New York, 1888; member of the American Medical Association; served on the staffs of the Jamaica (N. Y.) Hospital and the Roosevelt Hospital; died July 4, aged 90, of generalized arteriosclerosis and gangrene of the legs.

Andrew William Marks Row, Marine City, Mich.; Trinity Medical College, Toronto, Ont., Canada, 1896; died July 1, aged 69, of acute dilatation of the heart and asthma.

Rudolph George Schroth, Chicago; National Medical University, Chicago, 1904; member of the American Medical Association; died July 17, aged 68, of carcinoma of the stomach.

Walter Wesley Sessions ☉ Sumner, Ga.; Atlanta School of Medicine, 1911; honorary member of the Medical Association of Georgia; died May 21, aged 69, of chronic nephritis.

Jesse Shoup ☉ Washington, D. C.; Jefferson Medical College of Philadelphia, 1891; an associate of the American College of Physicians; served on the staffs of the Garfield and Doctors hospitals; died July 21, aged 80, of heart disease.

Samuel Gordon Sloan, Elmore, Ohio; University of Toronto Faculty of Medicine, Toronto, Ont., Canada, 1924; served with the Canadian Expeditionary Forces during World War I; interned at St. Vincent's Hospital in Toledo; died July 3, aged 47, of cerebral hemorrhage.

Martin Luther Sowers, Far Rockaway, N. Y.; University College of Medicine, Richmond, 1913; specialist certified by the American Board of Otolaryngology; a captain in the medical corps of the U. S. Army overseas during World War I; member of the American Medical Association; served on the staffs of the New York Eye and Ear Infirmary, Neurological Institute and the Manhattan Eye, Ear and Throat Hospital, all of New York, and St. Joseph Hospital; drowned while swimming at Long Beach, July 27, aged 53.

Henry Steible, Hammond, Ind.; Jenner Medical College, Chicago, 1900; for many years police surgeon for the police department in Chicago, where he had been on the staff of the Alexian Brothers Hospital; died July 14, aged 69, of acute cardiac decompensation.

Robert Benjamin Stevenson, Columbus, Ohio; Ohio State University College of Medicine, Columbus, 1912; member of the American Medical Association; a captain in the medical

Frank Curtis Titus, Toledo, Ohio; Illinois Medical College, Chicago, 1903; member of the Toledo Academy of Medicine, the American Urological Association and the American Medical Association; served during World War I; died July 14, aged 67, of coronary occlusion.

Mary A. Huban Traiser, Boston; Middlesex College of Medicine and Surgery, Cambridge, Mass., 1927; member of the staff of the Carney Hospital; died June 19, aged 65, of heart disease and chronic myocarditis.

William Wesley Ward @ Alexander, Ark.; University of Arkansas School of Medicine, Little Rock, 1902; held various offices in the Saline County Medical Society; served during World War I; school director and formerly mayor; died June 18, aged 75, of heart disease caused by asthma.

Arthur Weaver White @ Oklahoma City; Rush Medical College, Chicago, 1902; professor emeritus of clinical medicine at the University of Oklahoma School of Medicine; specialist certified by the American Board of Internal Medicine; fellow of the American College of Physicians; served during World War I; member of staff St. Anthony Hospital; chief of clinical medicine and consultant in gastroenterology, University Associated Hospitals; died June 11, aged 68, of coronary occlusion.

MAJOR JOHN E. ADAMS
M. C., A. U. S., 1911-1944

CAPT. JULIUS A. HENE
M. C., A. U. S., 1908-1944

CAPT. WILLIAM D. DAVIS
M. C., A. U. S., 1913-1944

corps and chief of the laboratory staff at an Army hospital in Hot Springs, N. C., during World War I; on the staffs of the White Cross and Mercy hospitals; died in the Mount Carmel Hospital July 13, aged 55, of coronary occlusion.

William H. Swain @ Martin, Ga.; Gate City Medical College, Dallas, Texas, 1907; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1914; commissioner of Stephens County for many years; on the staff of the Stephens County Hospital, Toccoa, where he died May 20, aged 76.

Elizabeth Wiltshire Wright @ Mount Vernon, N. Y.; Laura Memorial Woman's Medical College, Cincinnati, 1903; Boston University School of Medicine, 1909; died in Hawthorne, July 3, aged 69, of carcinoma of the breast.

Charles Henry Zander, Oakland, Calif.; University of Minnesota College of Medicine and Surgery, Minneapolis, 1909; member of the American Medical Association; died in the Providence Hospital June 15, aged 65, of myocardial infarction and arteriosclerosis.

KILLED IN ACTION

John Edwin Adams, Los Angeles; University of Virginia Department of Medicine, Charlottesville, 1936; interned at the Virginia Mason Hospital in Seattle; served a residency at the University of Virginia Hospital, Charlottesville, the Children's Hospital and Los Angeles County Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States, on Aug. 1, 1941; assigned to Hoff General Hospital in Santa Barbara; promoted to major; killed in action in the North African area Jan. 24, 1944, aged 32.

Julius A. Hene, New York; Medizinische Fakultät der Universität Wien, Vienna, Austria, 1936; interned at the Harlem Hospital; began active duty as a first lieutenant in the medical corps, Army of the United States,

on July 1, 1942; assigned to 10th Medical Battalion, Camp Hale, Pando, Colo.; later promoted to captain; killed in action in Stalag, Germany, Dec. 23, 1944, as the result of an air attack, aged 36.

William Dewey Davis, Pomona, Calif.; University of Chicago, the School of Medicine, 1939; member of the American Medical Association; interned at the Los Angeles County Hospital in Los Angeles; diplomate of the National Board of Medical Examiners; began active duty as a first lieutenant in the medical corps, Army of the United States, on May 15, 1942; later promoted to captain; killed in action in the Southwest Pacific area Aug. 2, 1944, aged 30.

Correspondence

UNCONTROLLED USE OF ORAL AMEBICIDES

To the Editors: The article in *The Journal*, August 11, by Silverman and Leslie on the "Toxic Effects of Diiodoquin" serves as a timely warning against what I believe is an increasing tendency to the somewhat careless and uncontrolled use of the oral amebicides. During the past year I have seen or heard of several amebiasis patients who, because of recurrent attacks of diarrhea or dysentery, have been taking repeated three week courses of an orally administered amebicide. Rest intervals between treatments have seldom been more than a week or two because of the recurrence of symptoms. Last month I saw 1 of these patients who sought relief mainly for an extensive dermatitis covering the entire body and diagnosed by several competent dermatologists as a purpuric infection probably contracted in India five years ago. Three years ago, in Iran, an attack of dysentery was diagnosed as being due to *Endamoeba histolytica*. Since then he has had repeated attacks of dysentery and, for the past year on the recommendation of several physicians, has been taking diiodoquin almost continuously. His dermatitis had been getting much worse during the past four months. I stopped the diiodoquin and substituted carbarsone plus vitamin therapy, and within three weeks the dermatitis had greatly lessened and the dysentery was relieved.

Many practitioners are now, or soon will be, for the first time faced with the problem of treating amebiasis. Undoubtedly the incidence of amebiasis in this country will be greatly increased with the return of troops and civilian workers from the tropics. While many of these individuals infected with *E. histolytica* have been properly diagnosed and treated, some will remain un cured and suffer relapses. These and others as yet undiagnosed, who may develop symptoms months or years after their original infection, will serve as carriers for the spread of amebiasis. Most authorities recognize the seriousness of this type of disease and agree that amebiasis is characterized by (a) difficulty in eradication of the ameba, (b) rapid tendency of *E. histolytica* to become "drug fast" to a specific amebicide, (c) chronicity of symptoms with frequent relapses of diarrhea or dysentery, (d) a large number of individuals who do not have diarrhea or dysentery but suffer from vague gastrointestinal symptoms and (e) the asymptomatic carrier of *E. histolytica*. The complete eradication of the ameba from the human host is difficult and requires well controlled therapy and a careful follow up study of the stools over a suitable period of time to determine cure.

The physician who undertakes to treat amebiasis must, first of all, be sure of the diagnosis. Too many physicians rely on their own ability to examine the patient's stool and too often imagine that cysts of *E. histolytica* are found when actually they see plant cells, yeasts or, rarely, nonpathogenic cysts. Also few clinical laboratory technicians should be entrusted with the responsibility of diagnosing stool specimens for *E. histolytica*. I recall 2 cases of chronic diarrhea diagnosed by a clinical laboratory as amebiasis, which were accordingly treated for this for several months before the correct diagnosis of cancer of the bowel was made. On the other hand, amebic infection should not be ruled out until several properly obtained and competently examined stools have been checked.

Several effective amebicides are now available. The Phenylcopol Beta chinolone (Vatium), carbarsone and emetine hydrochloride and N, N, R, resorcinol, chloroquin, diiodoquin and acetasone (Tovarsol) as amebicides. Since all these drugs are

potentially toxic and capable of producing untoward reactions, their use should be governed by certain definite rules: (a) treatment should be limited to a short period of from ten to fourteen days; (b) a rest period of at least two or three weeks should be followed and the stools found positive for the amebias before another course of treatment with one of the oral amebicides is started; (c) the iodine containing compounds chinolone, vatium and diiodoquin and the arsenicals carbarsone and acetasone are contraindicated in patients showing or suspected of having liver damage or known to have drug sensitivity; (d) none of these drugs should be used empirically for the treatment of a non amebic diarrhea; (e) emetine hydrochloride should not be used in weakened individuals or those with heart damage, because this drug has a definite toxic action on the heart and neuromuscular system. Of these drugs, emetine has been used the longest because it effectively stops the dysentery in a day or two. However, because of its toxic effects, many clinicians now hesitate to use it. They prefer to tide over the acutely ill patient suffering from a rapidly dehydrating and exhausting dysentery by the judicious use of *lindanum* or *paraperone* until the orally administered amebicides have had time to accomplish relief of symptoms. In such cases, in addition to correcting the loss of fluids from the body, prompt attention should be given to treating the *acanthamoeba* which is usually present.

With respect to the toxicity of diiodoquin and the iodine containing amebicides, Silverman and Leslie apparently have overlooked our recent articles on this subject (David, N. A.; Phatak, N. M., and Jener, E. R.; *J. Pharmacol. & Exper. Therap.*, 72:11 [May] 1941; *Am. J. Trop. Med.*, 24:20 [Jan.], 1942). In this work we were able to establish a definite L.D.₅₀ for diiodoquin in guinea pigs and kittens, which we attributed to the variable absorption of the drug. However, the fact that some of the treated animals died from each of the various orally administered doses used (from 50 mg. per kilogram to 2 Gm. per kilogram) indicated that sufficient absorption took place to kill the animal. Further proof that it is possible to absorb appreciable amounts of iodine when diiodoquin is orally administered was shown by studies of the blood iodine level in man before and after treatment with a modified course of diiodoquin. In 10 persons the normal blood iodine ranged from 5.3 to 12.02 micrograms per hundred cubic centimeters and, following diiodoquin administration of one tablet three times daily for ten days, increases in the blood iodine up to 35.6 to 457.25 micrograms per hundred cubic centimeters were noted. Four of these patients complained of the onset of pruritus and/or anal irritation soon after the start of treatment, 2 of postile "discomfort" and 1 of an increased sense of skin warmth. About the same results and symptoms were noted in another group of 9 students given the usual ten day course of vatium, although individual variations in the increase of blood iodine levels were less. It should be noted that we administered diiodoquin in doses of one tablet only three times daily for ten days rather than in the recommended therapeutic dosage of from seven to ten tablets daily for fifteen to twenty days. This larger dosage and prolongation of treatment would undoubtedly increase the degree of iodine absorption and the likelihood of toxic symptoms. I feel that if a drug is an effective amebicide it should accomplish its purpose within a period of ten days. Since we found that iodine absorption does occur after diiodoquin as well as vatium and chinolone (unpublished results) and that these drugs can kill animals at certain dosages and cause untoward symptoms in man, the physician should prescribe these compounds with some respect.

NORMAN A. DAVID, M.D., Portland, Ore.,
Professor of Pharmacology, University of Oregon
Medical School.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Alabama State Medical Assn. Journal, Montgomery 15:1-32 (July) 1945

- Breast Feeding. Ruth R. Berrey—p. 1.
Epiploic Appendage: Its Role in Production of Acute Abdominal Symptoms. W. C. Simpson—p. 3.
Effects of Arteriovenous Fistula on Cardiovascular System: Report of Case of Arteriovenous Fistula of Common Carotid Artery and Internal Jugular Vein. D. C. Donald and B. Meadows—p. 5.

Gelatin Solution as Plasma Substitute.—Steigmann and his collaborators studied the effects observed on hospital controls from administering gelatin solutions in different strengths and different admixtures regarding (1) hemodilution following one or more infusions, (2) changes in the blood, (3) liver and kidney function and (4) toxic reactions. The gelatin used in this study was supplied ready for use in solutions of 5 per cent and 2.5 per cent gelatin in isotonic solution of sodium chloride, 5 per cent gelatin in dextrose and 5 per cent gelatin in isotonic solution of sodium chloride reinforced with tryptophan, tyrosine, methionine and leucine. The gelatin solution was prepared from calcium gelatinate. The solutions were used in 82 hospital controls, who received 169 liters of gelatin solution during 130 infusions, each patient receiving from 1 to 10 liters. All infusions were given intravenously. Amounts from 2,000 to 10,000 cc. were tolerated without ill effects. Thrombosis of and pain in veins into which gelatin is repeatedly given were not uncommon. Some reactions were obviated by boiling all rubber tubing after infusion in alkaline solution. No untoward results following the administration of gelatin solution were observed in regard to the liver, kidney or hemopoietic system except for an increase in the sedimentation rate of red blood cells. The fact that gelatin is nonantigenic makes this substance promising as a plasma substitute.

Inhibitive Effect of Gastric Lavage on Tubercle Bacilli.—Schwartz reports studies that were carried out at Glen Lake Sanatorium, Oak Terrace, Minn. It was found that substances are present in many gastric lavages which can inhibit partially or completely the growth of tubercle bacilli. Incubation at 37 C. permits the inhibitory substances to act most readily,

but ice box temperatures do not prevent their action. False negative cultures and failure to infect guinea pigs may result if gastric contents are not treated and inoculated immediately, especially in those specimens which contain only a few bacilli. The practice of accumulating several specimens of gastric contents over a period of days and pooling the combined specimens should be discouraged, because results have shown that the time lapse between receipt and treatment for culture may offset any advantage gained by the additional specimens.

Penicillin in Meningitis.—This study by White and his collaborators of 71 patients with acute meningitis treated with penicillin, of whom 50 had pneumococcal, 12 meningococcal, 5 streptococcal and 4 staphylococcal meningitis, was made possible by the cooperation of a large number of physicians in eighteen hospitals in the Philadelphia area. Penicillin was often effective in pneumococcal, meningococcal and streptococcal meningitis after adequate sulfonamide therapy had failed to produce the desired response. In pneumococcal meningitis the presence of subcranial foci and advanced age were cardinal factors in influencing the mortality rate. Intrathecal penicillin therapy does not appear harmful. Intracisternal injection seems to be the most effective route of intrathecal administration. Although penicillin administered by the systemic route alone may have a curative effect in selected cases, it seems preferable to supplement systemic administration with intrathecal injections of the drug by the cisternal route. The superiority of penicillin over other forms of chemotherapy is most clearly demonstrated in staphylococcal meningitis. It is likely that best results will be obtained through the use of a combination of penicillin and sulfonamides in systemic therapy, and penicillin intrathecally.

Transmission Experiments with Feces in Infectious Hepatitis.—Transmission experiments in human volunteers have shown that the causative agent of infectious (epidemic) hepatitis may be present in the feces of persons with the active disease. Neefe and his associates administered orally pooled specimens of feces from 6 subjects during various stages of homologous serum hepatitis to 19 healthy volunteers. None of these showed evidence of hepatitis during a four to six month period of observation, suggesting that the causative agent either was not present in the feces or was not active when administered by the gastrointestinal route. Pooled specimens of feces from patients with infectious (epidemic) hepatitis were administered orally to healthy volunteers. Hepatitis occurred within twenty-six days in 6 of 12 subjects, confirming the observation of others that the causative agent is present in the feces of patients with the active disease. Pooled specimens of feces obtained from 2 volunteers during the preicteric and icteric stages of experimentally produced infectious (epidemic) hepatitis were administered orally to 7 healthy volunteers. One developed the disease after twenty-six days, indicating that the agent was present in feces obtained during the active disease. Pooled specimens of feces from the same 2 volunteers three

weeks after the disappearance of jaundice also were administered orally to 7 healthy volunteers. None developed hepatitis during a four month period of observation, suggesting that the agent was not present in the feces three weeks after the disappearance of icterus.

Tsutsugamushi Disease.—Machella and Forrester present clinical and laboratory data on a series of 24 American and 40 Chinese patients who had a disease which appeared to be identical with tsutsugamushi or Japanese river fever, also called mite or "scrub" typhus. The exact incubation period was rarely determined, all of the patients admitted having been in the jungle during the several weeks prior to the onset of the illness. A typical primary ulcer was present in 43 of 64 cases. The initial lesion began as a red painless macule, which in a few days became papular. A small excoriation then appeared on the dome of the papule, which soon became deeper and filled with a black eschar. The most striking feature of the patient's general appearance was apathy. The average duration of fever was 17.4 days. The blood pressure was usually low during the course of the febrile period and then gradually came up to normal during the period of convalescence. A typical rash was noted in 33 of 63 cases. The spleen was palpable in 35 of the 40 patients. Regional lymphadenopathy was demonstrable in all but 4 of those patients in whom a primary eschar was present. Generalized peripheral lymphadenopathy was demonstrated in 60 of 64 patients. Characteristic changes in the eye-grounds were found in a large percentage of the patients. Cough was also present in over half of the patients. Roentgen examination of the chest revealed the presence of pathologic changes in 24 of 40 patients. The nature and duration of positive Weil-Felix reaction (proteus OXK) are described, and a difference between the OXK titer in patients with and without primary ulcers is pointed out. Azotemia was noted during the second or third week of fever. One of the patients in the series appeared to undergo a true relapse. The mortality in the series was 1.5 per cent.

Transient Focal Pulmonary Edema.—Peirce and his associates point out that a considerable number of the reported cases and also cases in their series presented clinical symptoms and signs compatible with pulmonary tuberculosis: cough, slight to moderate malaise, loss of weight, changes in physical findings, some crepitant rales, history of exposure or indication of previous tuberculosis, some with mildly positive skin reactions. In the series observed by the authors, the x-ray studies presented sufficient characteristics to differentiate their cases from pulmonary tuberculosis. The distribution is not that commonly manifest in tuberculosis. The individual foci are usually associated with the lesser anatomic divisions or segments of the lungs but do not have a true lobular configuration. Nor is there an associated peribronchovascular infiltration toward the lung root. The amorphous character of the individual focus, the rapid migration from one portion of the lung to another without the use of connecting pathways, the transient nature with short duration are notable features. The texture of the individual roentgenographic shadow is that of a haze or cloud,

sometimes so confluent over so great an amount of lung tissue as to suggest consolidation; but none have been actually dense enough to be so considered. Any atypical, evanescent, parenchymal or peritubercular shadow should be regarded with caution, especially when it does not conform to a common anatomic pattern. Such a shadow should be observed frequently over a few days to weeks. These evanescent and variable areas of increased pulmonary density are focal zones of transient pulmonary edema, probably associated with an allergic state; they are local manifestations of the individual's response to an allergen elsewhere. It is possible that, if such a state should persist long enough, a pattern suggestive of periarthritis nodosa might be established. Eosinophilia and roentgenographic pulmonary involvement are out of proportion to the clinical evidence of disease. Extreme care must be exercised to ensure that no such cases are stigmatized with the diagnosis of tuberculosis on one roentgenographic observation. Careful clinical history and physical examination are still required for diagnosis.

Bed Rest in Tuberculosis.—According to Peck and Willis, pulmonary infarction does not appear to be a danger of great consequence to the tuberculous patient who is kept at bed rest. Pulmonary infarction and embolism of the pulmonary artery were found in only 1.5 per cent of 751 necropsies on tuberculous persons. Other dangers which may be associated with bed rest in this disease are the failure (1) to obtain adequate pulmonary drainage, (2) to meet the emotional maladjustment so often present and (3) to correlate properly collapse therapy and a bed rest regimen. The evils which adhere to bed rest are incident to its mode of application. Good bed rest will avoid these dangers and retain its full therapeutic value. Poor bed rest is often therapeutically inert and can be aptly called bed fatigue. Proper bed rest should include mental repose, muscular relaxation and adequate pulmonary drainage and should not be thought of as mere regimentation in recumbency. Bed rest is inherently valuable but unreliable when administered indifferently. It warrants constant, critical attention by the physician in order to insure good results.

Chemotherapy in Experimental Tuberculosis.—Of 300 compounds tested in vitro as possible chemotherapeutic agents against *Mycobacterium tuberculosis* var. *hominis*, 39 of the more promising were tested in guinea pigs inoculated with tubercle bacilli. Although slight and irregular suppression of the infection occurred with neosynephrin sulfathiazolate, diasone and a combination of sulfadiazine and propylene glycol, in no case did this appear adequate to justify clinical trials. The beneficial results obtained have all been characterized as retardations of the disease and not as cures, although in occasional animals all lesions appeared to have been totally suppressed. Cutting and his associates think that more striking results of other investigators may be due in part to the use of much smaller inocula of tubercle bacilli and older, and hence more resistant, guinea pigs.

Pentothal Anesthesia.—In an evacuation hospital where pentothal was administered to more than 400 patients, it comprised about 15 per cent of all the anesthetics given. Records were kept of 200 consecutive cases. Intravenous administration of pentothal is a valuable and safe anesthetic in experienced hands. The induction dosage is variable and has no direct relation to the amount required for maintenance of the anes-

thetia. Both the induction and maintenance requirements are diminished with morphine, nitrous oxide and block anesthesia. The anesthesia can be divided into two categories, "light pentothal" and "deep pentothal" anesthesia. Light pentothal should be used for simple surgical procedures. Deep pentothal usually abolishes deep reflexes such as laryngospasm. The temperature of the solution had no effect on the anesthesia. Solutions which had been stored for some time after preparation were as effective as freshly prepared solutions and were used without apparent harmful effects.

Histaminic Cephalgia with Duodenal Ulcer.—Alford and Whitehouse treated 50 cases of headache and found that 4 were typical of histaminic cephalgia as first described by Horton. One case of histaminic cephalgia presented an unusual complicating feature. A man aged 34 first noticed about fifteen years ago sharp, needle-like pain, localized to the region of the right eye. This pain lasted about an hour and came at any time of the day or night. The right eye watered and became severely injected, and the right nostril became obstructed. During this fifteen year period he had had free intervals as long as three months and then again suffered from as many as three headaches in twenty-four hours. About twelve years ago he noticed attacks of gnawing pain in the epigastrium for the first time. On a number of occasions he vomited coffee ground material and several times had vomited a cup of bright red blood. Tarry stools had been observed on a few occasions. The epigastric pain was relieved by soda and food. Hospitalization on an ulcer diet usually brought relief of gastrointestinal symptoms in about two weeks. Roentgenoscopic and roentgenographic examination showed a deformity of the duodenal cap, just beyond the pylorus, and a shadow suggestive of a small crater was seen in this area. Horton reported 10 cases of histaminic cephalgia complicated by acute duodenal ulcers with demonstrable crater formation. The authors studied the relationship between histaminic cephalgia and the duodenal ulcer in their patient. During several attacks of headache the acid curve was high, similar to a curve resulting from the injection of histamine. During periods free from headache, the acid curve showed a low acidity. Following treatment with histamine the headache and the ulcer crater both disappeared, with no change in the essential gastric secretory mechanism.

Penicillin in Cutaneous Disease.—Franks and his associates used the sodium salt of penicillin in a solution that contained from 400 to 600 Oxford units per cubic centimeter. This was applied to the affected areas as a wet dressing, so that the lesions were constantly dampened with the penicillin solution. To prevent the solution from evaporating rapidly, the saturated

gauze was covered with oilcloth. For the intramuscular injections, 20,000 units of penicillin was mixed with 2 cc. of isotonic solution of sodium chloride. Penicillin was useful in the treatment of sycosis vulgaris, impetigo contagiosa and gonorrheal conjunctivitis when used locally. Whether penicillin was used intramuscularly or intravenously, it proved to be beneficial for sycosis vulgaris, pustular acne, Ludwig's angina and chronic cutaneous diseases complicated by secondary infection with pyogenic organisms. Penicillin therapy was of no value in psoriasis vulgaris, lichen planus, favus, lupus erythematosus, pemphigus foliaceus, and seborrheic and chronic fungous dermatitis.

Late Secondary Tonsillar Hemorrhage.—Tonsillectomy and adenoidectomy are not infrequently complicated by secondary hemorrhage occurring generally on the sixth or the seventh day. Neivert learned that in Europe these secondary hemorrhages are much less frequent and the difference that seemed significant was that acetylsalicylic acid is extensively prescribed in this country, as it also is in Canada and England, whereas in central Europe aminopyrine is the drug of choice. Workers in the department of biochemistry of the Wisconsin Agricultural Experiment Station showed that salicylic acid and sodium salicylate induced hypoprothrombinemia in rats kept on a ration low in vitamin K. The animals could be protected against this action of salicylic acid by administration of a vitamin K preparation. Estimations of prothrombin time done on a large number of patients at the author's hospital revealed that in some subjects a daily dose of 2.4 Gm. of acetylsalicylic acid will produce an elevation in prothrombin time on the next day, whereas in others it will be much longer before a significant rise will be discernible—but such a rise will occur eventually. These studies afford corroboratory evidence that administration of salicylates results in hypoprothrombinemia. In view of the fact that acetylsalicylic acid, by virtue of its effectiveness and its comparative nontoxicity, is the most widely used analgesic, the author thought it advisable, rather than to eliminate it, to combine it with an agent which will counteract its effect on prothrombin. The water soluble vitamin K-like compound synkayvite (tetrasodium 2-methyl-1,4-naphthohydroquinone diphosphoric acid ester) prevents this undesirable side effect of acetylsalicylic acid. The combined acetylsalicylic acid and synkayvite medication was tried on a broader scale. Only 4 among 283 patients were troubled by late tonsillar bleeding. The author concludes that while in rare cases the cause of late post-tonsillectomy hemorrhage may be trauma, menstruation, infection, deficiency of vitamin C or some blood dyscrasia, observations suggest that one of the most important factors is a reduction in the prothrombin of the blood brought about by the use of acetylsalicylic acid or salicylates.

Acetylsalicylic Acid a Probable Cause of Secondary Hemorrhage After Tonsillectomy.—Singer points out that hemorrhages that occur on the sixth or seventh day after tonsillectomy are much less frequent in the clinics and hospitals of central Europe than they are here. A comparison in the pre-operative and postoperative regimens used in this country and abroad revealed only one significant difference. This was the administration in this country of acetylsalicylic acid to relieve postoperative pain. In central Europe acetylsalicylic acid is never used as a postoperative analgesic; aminopyrine is used instead. A postoperative regimen free of acetylsalicylic acid in a series of 75 cases resulted in the conspicuous absence of hemorrhagic inflammation and of secondary hemorrhage in all

instances. The prothrombin lowering effect of salicylates described by a number of authors seems to be a plausible explanation for the occurrence of secondary post-tonsillectomy hemorrhage.

Oral Administration of Amino Acids in Bleeding Peptic Ulcers

Eleven patients with severe hemorrhage from peptic ulcer were treated with the usual Sippy diet, to which was added a daily oral intake of from 100 to 200 Gm. of a mixture of amino acids. The serum protein returned to normal, on the average, within 10.2 days. In a control group of 6 patients who were given the Sippy diet without the addition of the amino acids the serum protein returned to normal, on an average, after nineteen days. The treatment was well tolerated. Levy stresses that the oral use of a mixture of amino acids in the treatment of peptic ulcer, especially in the presence of massive hemorrhage, has advantages; it acts as a buffer combining with acid, thus acting as an antacid; it spares digestive activity on the part of the gastrointestinal tract, and it is effective in treating the hypoproteinemias following massive hemorrhage.

Pathogenesis of Intestinal Polyps. Atwater and Bergen studied material obtained at necropsy at the Mayo Clinic between October 1912 and February 1943. The mucosa of the entire colon was examined with a hand lens, tissues being taken from the several portions of the colon as well as from regions which aroused suspicion. Specimens and sections obtained from colons in which no abnormality could be found either grossly or microscopically were designated as "pure" controls. Some

sections were obtained from colons in which polyps existed; the sections in this part of the control group were taken both adjacent to and distant from such polyps. Sections obtained from these colons were called "impure" controls. The sections displaying polyps were divided into those showing benign polyps and those showing malignant polyps. Any structure protruding in abnormal fashion above the normal mucosa, sessile or pedunculated and having a plandular character, was considered a polyp. Fibromas, myxomas, hemangiomas, lymphangiomas, lipomas or other benign tumors were not included. It was possible to trace the pathogenesis of intestinal polyps from the earliest epithelial change to frank carcinoma. One way in which polyps are formed is through epithelial change. The incidence of colonic polyps including tiny sessile lesions was 69 per cent in the 241 cases studied. No difference was found in the occurrence of polyps in the two sexes. The mean average age of patients harboring polyps was 61 years. Lymphoid structures at most seem to play only a casual role in the pathogenesis of intestinal polyps. In view of the evidence and its abundant verification in clinical experience, it would seem that the term "benign polyp" should not give the idea of an innocent tumor but rather of one stage in the pathogenesis of a carcinoma.

New Method for Production of Potent Inactivated Vaccines. Levinson and his co-workers have developed a new method for completely killing turbid suspensions of bacteria and viruses in less than one second by exposing continuously flowing thin films to far and extreme ultraviolet irradiation. Intensity, film thickness, time of exposure and distance have been so standardized that experiments could be duplicated with consistent results. By means of this new technique, suspensions containing approximately one billion organisms per cubic centimeter of the following bacteria were completely killed in 0.17 to 0.33 second exposure to ultraviolet rays: *Escherichia coli*, *Cherthella typhi* (strain 58), *Salmonella enteritidis*, *Staphylococcus aureus*, *Streptococcus childers* and *Diphtheria pneumoniae* (type 1). Four per cent uncentrifuged brain tissue suspensions infected with fixed rabies or lymphocytic choriomeningitis virus were completely inactivated by irradiation for 0.17 to 0.33 second; an exposure twice this length was necessary to inactivate highly centrifuged 4 per cent suspensions of St. Louis encephalitis virus. Several lots of rabies vaccine

inactivated by this irradiation technic consistently induced a higher degree of immunity in mice than control phenolized vaccines. The irradiated rabies vaccines exhibited no significant loss of potency after six months' storage at 5 C. Two lots of St. Louis encephalitis vaccine inactivated by this irradiation technic conferred a high degree of immunity in mice. Irradiation of rabies or St. Louis encephalitis viruses beyond the optimal time necessary for complete inactivation causes progressive diminution of antigenicity.

Carotid Sinus Syncope.—Roseman and his associates present an unusual case of a sensitive carotid sinus syncope developing after ligation of the common carotid and internal carotid arteries. The patient originally had multiple severe injuries about the head with the resultant production of an arteriovenous aneurysm of the left internal carotid artery and cavernous sinus. An unusual opportunity for follow-up was afforded by the use of the electroencephalogram and the electrocardiogram. The control electroencephalogram was characterized by the presence of high voltage fast activity, which disappeared with the abeyance of the subjective noises in the head and reappeared with the intermittent presence of the swishing sounds heard by the patient. The sensitive carotid sinus appeared on the side of the ligated carotid vessels some two months after operation and is attributed to scar tissue formation, with resultant tension stimulation of the left carotid sinus each time the head was turned to the right. Electroencephalographic and electrocardiographic tracings of the syndrome are recorded. Cure of the sensitive left carotid sinus occurred following complete excision of the carotid bifurcation.

Splenectomy for Hemolytic Jaundice in the Aged.—James and Evans present the history of a woman aged 70 who developed severe hemolytic anemia. The case is of interest because it yields information on three phases of the diagnosis and treatment of hemolytic jaundice. First, the disparity among results obtained with various types of erythrocyte fragility tests deserves comment. Second, an attempt to classify the patient's anemia as either the congenital or the acquired form helps to evaluate recent studies of certain features of these syndromes. Third, the patient's advanced age at the time of onset and of splenectomy is of interest, since only 1 other case of splenectomy for hemolytic jaundice over the age of 70 has been reported in the literature. Study of the literature revealed 15 cases, including the 1 here reported, in which the onset of hemolytic jaundice occurred at or beyond the age of 50 and in

which not all the essential criteria for a diagnosis of congenital hemolytic jaundice were present. The family and past histories were noncontributory. Symptoms and physical signs included loss of energy, anorexia, weakness, palpitation, shortness of breath on exertion, pallor, jaundice and enlargement of the liver and, somewhat more regularly, of the spleen. Of the 15 cases, 5 showed definite improvement after splenectomy. In 10 of the cases splenectomy was ineffective or resulted in acceleration of the downhill course. The cases reviewed demonstrate that splenectomy may save the lives of elderly persons with acquired hemolytic jaundice and that it should not be regarded as a useless procedure. Although good results following splenectomy are more likely in a patient with increased erythrocyte fragility, spherocytosis and a spleen typical of congenital hemolytic jaundice than they are in others, it is sometimes of value in patients whose clinical picture lacks one or more of these characteristics.

*Dermatologic Aspects of Poliomyelitis. J. G. Reyes.—p. 1673.

Dermatologic Aspects of Poliomyelitis.—During the recent poliomyelitis epidemic in New York City, Reyes observed 84 children, their ages varying from infancy to 14 years, admitted to St. Francis Hospital with the diagnosis of poliomyelitis. The disease was more common in boys than in girls, the ratio being 5 to 1. In 98 per cent of the children lesions were located on both infrapatellar areas, on the anterior and lateral aspects of both ankle joints, on the dorsa of both feet, on both soles and on the malleoli. The lesions were symmetrical and were typically those of hyperkeratinization in the form of plaques, small papules or slightly verrucous elevations, with roughness and dryness of the skin of the legs. Lesions of these types and forms are encountered in cases of vitamin A deficiency. Their abundance seemed to be proportional to the severity of the poliomyelitic involvement, their prominence disappearing with the abatement of the disease. Among the children who were admitted for other lesions, only 1 in 8 had such skin manifestations. From the extremely high incidence of these skin lesions in poliomyelitis, Reyes deduces that vitamin A deficiency may be a predisposing factor of poliomyelitis. He advises that a diet rich in vitamin A should be given to all children, especially during the periods of epidemics, and this diet should be supplemented by cod liver oil or its concentrates. Since vitamin A deficiency will produce keratinization of the epithelium of the skin and the mucous membranes of the internal systems, it is possible that these structures which have been affected by the keratinizing metaplasia are open doors for the entrance of the poliomyelitis virus into the human body. It should be investigated whether the administration of vitamin A, either by mouth or parenterally, is of value in the treatment of poliomyelitis.

Buffer Precipitation Test for Malaria.—Bogen states that in troops returning from the South Pacific repeated smears taken over a long period of time may be negative, yet months later chills may recur or even appear for the first time. Microscopic studies usually fail to disclose such latent infections. A variety of immunologic technics have been proposed for the diagnosis of malaria, but the difficulty in obtaining specific antigens and the variability of the results obtained have precluded their general use. In 1939 Wolff of Colombo, Ceylon, reported that blood serum added to buffered distilled water became cloudy at a higher pH in malaria than in normal controls. The following year he described a simple buffer precipitation test, using only a few drops of serum and requiring little technical labor. The reaction is apparently due to a euglobulin which arises in the blood of malaria patients. Wolff found that normal human blood serum added to distilled water at pH 7.7 remains clear, but blood serum from malaria patients becomes cloudy. From this observation the buffer precipitation test has been developed. More than 3,000 such tests made at the author's hospital have confirmed the validity of this reaction. The reaction is strongest in active malaria between paroxysms and in recently recovered patients but remains positive for many months. The test offers valuable aid both in individual diagnosis and in the detection of malaria in large groups. It may have interesting possibilities in suggesting prognosis, in guiding suppressive and therapeutic measures and in evaluating cures.

Egg Allergy.—Sprague and Barnard point out that extremely sensitive allergic egg reactors may develop serious and possibly fatal allergic reactions if inoculated with the vaccines of yellow fever and typhus which are cultivated in chick embryo or yolk sac tissue. Each person should be asked if he is sensitive to egg before being given typhus or yellow fever vaccine. Persons with an egg sensitivity history should be skin tested with diluted egg white and egg yolk. If they show negative skin tests to 1:10 dilution, it is believed that the vaccine can be given safely. The knowledge of severe immediate reactions to ingested egg since childhood was a prominent feature in the histories of 2 cases reported by the author. This sensitivity is often only one manifestation of a generalized allergic state. If the sensitivity is discovered, it would appear wise not to submit them to inoculation of vaccines containing chick embryo products.

Replantation of Teeth.—Alexander defines replantation as the reinsertion of a tooth in its original socket from which it has been dislodged either by accident or by design. Replantation of dislodged anterior teeth can be done painlessly and quickly. Splinting or wiring of the tooth need be maintained for only three to five weeks. If the tooth is not devitalized before replantation, periodic check-ups by x-ray and vitality tests should be made. Should there be unfavorable developments, such as putrescence or pain, the tooth can be devitalized. The shorter the time between dislodgment and replantation, the better the chances for reattachment of the tooth.

Nicotinic Acid for Vasodilatation in Rheumatoid Arthritis.—Kurtz and his associates used nicotinic acid to produce vasodilatation in treating 36 patients with rheumatoid arthritis. In addition, 6 patients with osteoarthritis have been given at least one course. Among the 36 patients with rheumatoid arthritis there were only 7 in whom the disease had existed less than two years. In most of the patients the disease had steadily progressed despite varied types of therapy. Twenty-eight of the 36 patients were bedridden. The initial intravenous injection consisted of 200 cc. of a solution of 0.05 per cent nicotinic acid in isotonic solution of sodium chloride. If this was well tolerated, 400 cc. of a 0.05 per cent solution was given daily thereafter. In most instances this produced a feeling of warmth or prickling and a visible flushing of the skin lasting approximately an hour. If the flush was of shorter duration or the patient developed a tolerance to the drug, the strength of the solution was increased to 0.1 per cent. The solution was injected by slow drip requiring from one to three hours for completion. One patient was encountered who reacted with nausea, emesis and mild cyanosis, so that further treatment with nicotinic acid was not attempted. The most satisfactory method of oral administration was to give 50 mg. of nicotinic acid every fifteen minutes for three doses before breakfast and again later in the day, either before lunch or before supper, and before retiring. The drug was always administered when the stomach was empty. In some cases the oral dose had to be increased from 50 to 100 or 200 mg. In the group of 35 patients with rheumatoid arthritis significant improvement was determined subjectively and objectively in 25 and 26 patients respectively.

Toxoid Pastilles by Mouth for Restoration of Diphtheria Immunity.—Bousfield conceived the idea of a fairly firm gelatin sweet or pastille containing about 100 Lf units of formaldehyde toxoid, suitably flavored with some neutral agent such as peppermint. He tried the effect on himself, sucking four of the toxoid disks daily for seven days, without experiencing inconvenience. After additional observations on volunteers, he tried the effect on children. The method seems to be generally effective in subjects who have a demonstrable amount of antitoxin in the blood or who are definitely known to have reached the Schick negative level at some time in the past. Rises in serum antitoxin content are striking in some of the cases. While there is no evidence that the method will suffice to provide an adequate stimulus for primary immunization, it appears to be generally applicable to children and adults who have ever been immune in the past, provided the age and intelligence of the subject are sufficient to ensure that the disks are sucked slowly. Modification of the technic might still render primary immunization feasible. The treatment can be administered to immune and nonimmune subjects impartially without fear of producing local or general reactions, and thus, in cases which are known to have been immune in the past, a Schick test is not essential before using this method of reimmunization. While attractive to needle shy children, the greatest value of such a method might be in dealing with adults—e. g. nurses or men in the services—when it is so important that constitutional disturbance shall be avoided.

Thyrotropic Exophthalmos.—Zondek and Ticho describe 3 cases of exophthalmos which, according to the present classification, would have been designated as thyrotropic exophthalmos. The ophthalmic manifestations were of particularly severe degree. Two of them presented severe decalcification of the skull bones and enlargement of the sella turcica; this finding points to involvement of the pituitary-diencephalic region. In both cases there were diabetic dextrose tolerance curves. The abnormally high blood cholesterol level in 2 cases argued against hyperthyroidism. All 3 cases responded favorably to diiodotyrosine. In 1 case (postoperative exacerbation of the exophthalmos) diiodotyrosine, in combination with pituitary irradiation on two occasions, resulted in considerable improvement of the eyes (such as regression of proptosis and disappearance of chemosis and epiphora) and thus rendered surgical intervention unnecessary. In view of the fact that the part played by the thyrotropic hormone in the production of this type of exophthalmos is doubtful, while that of the pituitary-diencephalic system seems to be highly probable, the looser definition of "pituitary-diencephalic" exophthalmos is suggested.

Toxicity of DDT.—Cameron and Burgess state that American investigations and their own experiments with DDT suggest that there is a wide margin of safety in its use as an insecticide. There is no reason to anticipate danger to man

provided a maximum concentration of 0.5 per cent of DDT is insisted on for sprays. Only gross carelessness would be likely to lead to serious features. Even with long continued exposure to such sprays it is difficult to see how ill effects would be incurred. On the other hand, men handling higher concentrations should take precautions against skin contamination. Cleanliness is essential, the use of gloves and protective garments advisable. In spraying concentrates the use of respirators is advocated. Dry powders of DDT present no danger of absorption from the skin. It is only when oily solvents are employed that such risks are likely to arise, and here again there is much variation according to the type of solvent used. Ample warning of the approach to toxic levels is given in the form of anorexia, muscular weakness and fine tremors. If at this stage DDT is discontinued, complete recovery is the rule in animals. Even when liver damage has developed, a fatal issue is not necessarily inevitable if further DDT absorption is prevented. Difficulty arises when liver degeneration sets in without premonitory symptoms or associated nervous signs, and a fatal degree of hepatic insufficiency may be reached without warning. The authors have learned to attach importance to rapid decrease in body weight in such instances. Other features of value in assessing toxic absorption are the development of anemia and leukocytosis. A rise in blood calcium may also be suggestive. Prolonged contact with undergarments impregnated with DDT has not produced local or general disturbances in human subjects.

Storage of Skin for Autogenous Grafts.—Skin storage reduces the number of donor areas needed in multiple stage plastic repair. The patient is saved the pain of second or even third donor areas, which often cause more pain than the field of operation during the first forty-eight hours. The duration of each operation, after the first, is also lessened by the time it would have taken to cut a fresh graft. A spare piece of skin is available in case the graft partially fails. Stored skin can provide an experimental skin bank for investigating the problems of heterogenous grafting. A standard method has been developed for the storage of skin in a refrigerator which maintains a temperature of from 3 to 6 C. The graft is folded with its raw surfaces opposed as far as its shape allows. It is wrapped in a piece of tulle-gras and this in turn in a piece of gauze tightly wrung out of isotonic solution of sodium chloride. It is then placed in a sterile air tight screw topped glass bottle having a cubic capacity of 20 cc. It is held away from the small amount of fluid which collects in the bottle by insertion of a ring of rubber tubing or leadfoil for it to rest on. The power of growth of stored skin was proved by tissue culture of skin stored for eight days. Some of the refrigerated grafts were found to be sterile; others were infected with the normal contaminants of the skin, but despite the survival of these organisms on the grafts they had no harmful effects even after storage as long as seven months. The contact coagulum method of fixation has been employed to hold the stored grafts in position when their application at the bedside without an anesthetic has prohibited the insertion of stitches for pressure dressings. Matthews reviews the results of the first fifty grafts of stored skin. There is a possible relationship between refrigeration and increased resistance of the skin to infection.

Management of Traumatic Pyothorax.—The 44 cases on which Collis and his associates base their report are instances of total or almost total pyothorax and do not include cases of early infected hemothoraces in which the fluid present never became frank pus. The number is not large relative to the total of 710 admissions to the unit, but the high mortality of 27 per cent (12 cases) emphasizes its importance. Experience

has led the authors to believe that a localized empyema is sometimes unavoidable but that total pyothorax, with the possible exception of cases associated with esophageal injury or very virulent organisms such as hemolytic *Clostridium welchii*, is an avoidable condition. Provided pulmonary expansion is effected and is maintained from the onset of treatment, infection can produce only a localized empyema. The authors differentiate between cases of closed and of open pyothorax. In cases of closed pyothorax aspiration is carried out for the first few days, penicillin being introduced into the pleura after aspiration on alternate days. A portion of the ninth or tenth rib is then resected, all clot removed and drainage instituted just under the lateral edge of the erector spinae. Breathing exercises are started at once. A method of two tube drainage, with an additional apical tube, allows the cavity to be washed out and prevents the drain from becoming blocked.

Congenital Afibrinogenemia.—Henderson and his associates think that there is still too great a tendency to regard congenital "bleeders" of the male sex as hemophilic without adequate clinical and laboratory investigations having been made to eliminate other possible causes of the hemorrhagic diathesis. They report a case of congenital afibrinogenemia in an otherwise healthy boy of 11 years. Only 6 other cases of this disease have been recorded in the literature, but it seems probable that complete investigation of all congenital "bleeders" would reveal more cases. The principal clinical features of congenital afibrinogenemia are its hereditary character, a high incidence of consanguinity in the parents, the susceptibility of both sexes, a total absence of fibrinogen in the blood, complete incagulability of the blood, a bleeding time which is usually prolonged, a great reduction of capillary resistance, a low blood sedimentation rate and intermittent thrombocytopenia. Treatment of the severe hemorrhage is by intravenous transfusion with whole blood or nonprocessed plasma. Absence of fibrinogen is regarded as the principal cause of the hemorrhagic diathesis in congenital afibrinogenemia, but diminished capillary resistance may be a contributory factor. Four cases of congenital hypofibrinogenemia which have been recorded in the literature are reviewed. The principal distinction between congenital afibrinogenemia and congenital hypofibrinogenemia is that no clotting occurs in afibrinogenemia, whereas it is normal in hypofibrinogenemia.

Anticoagulating Action of Derivative of Camphor: Application in Phlebitis. C. Ollier and M. Matel. p. 83.

Marbled Blanching as a Alarm Sign of Ischemia.—Leriche thinks that marbled blanching is not usually given the attention it deserves. It does not as a rule occur alone but with accompanying signs, which are likewise neglected. It indicates irreducible ischemia. Sympathetic anesthesia, intra-arterial injection of procaine and ganglionectomy do not have any effect on it, because sudden marbled blanching and coldness of the hand or foot is always caused by a material obstruction in the circulation. Direct intervention at the involved point of the artery is an absolute necessity. Generally, marbled blanching occurs suddenly and without pain. The peripheral part is white and cold up to a certain point, where without transition the skin is warmer than on the opposite side. At the same time the extremity is insensitive; analgesia is absolute until the

patient attempts to move it. The peripheral pulse cannot be felt if this triad of symptoms is present. The author has seen marbled blanching after simple fractures of the elbow and of the lower third of the leg. The contused artery or arteries are rapidly thrombosed. Operating on the second day, Leriche has found the posterior tibial artery thrombosed and the anterior tibial artery compressed by an extensive ecchymotic infiltration. Resection of the posterior tibial artery, freeing of the anterior tibial and reduction of the fracture saved the foot. Marbled blanching is observed also in embolism, but in this case it does not last long; violet spots soon appear. He has not observed marbled pallor in arteritis, but he has seen the aforementioned triad in massive thrombosis of aneurysm. He has collected 6 cases of this type, of which he describes 1, in which the popliteal aneurysm was first removed and later a low amputation was done. This was better than an immediate amputation above the aneurysm, that is, in the thigh. Leriche stresses that in the sudden massive ischemic states, such as in embolism, prompt removal of the obstacle will save the extremity from amputation.

Cancerous Erythroblastic Anemias. R. Golin. p. 118.

Megakaryocytic Aleukemic Myelocytosis.—According to Delcourt the term megakaryocytic aleukemic myelocytosis is applied to a syndrome which in its complete form presents hepatomegaly, splenomegaly, subicterus or mild icterus, anemia, myeloma and normoblastosis, and severe myeloid and megakaryocytic reactions in the spleen, the liver and often the lymph nodes. The formation of multinuclear cells in the hepatic sinusoids frequently and the continuation of these with Kupfer's cells occasionally can be demonstrated. The nosologic place of megakaryocytic aleukemic myelocytosis is difficult to establish. The characteristic microscopic lesions group the syndrome with the reticuloses. Like these, megakaryocytic aleukemic myelocytosis is a rare disorder and its clinical diagnosis is difficult. The hematologic signs which accompany it occur in other blood dyscrasias, particularly in the erythroblastic anemias or in anemias resulting from bony spread of a cancer. Features of hemopoietic centers do not always show the pathognomonic element, the megakaryocyte. In the majority of cases diagnosis is not definite until after death. Exceptionally it may be possible to make the diagnosis by means of biopsy of the liver and spleen. The author reports a case of megakaryocytic aleukemic myelocytosis, in which there was intense erythroblastic reaction in the peripheral blood and hemopoietic centers. The patient, a woman aged 68, died, the immediate cause of death being an acute cardiac insufficiency. Necropsy revealed a pronounced myeloid reaction of the spleen with the formation of numerous megakaryocytes. This reaction was less severe and less systematized in the liver. The pleokaryocytic cells which were found there seemed to have an autochthonous origin at the expense of Kupfer's cells. There exist a transport of myeloid cells and of typical megakaryocytes to distant organs such as the thyroid, the parathyroids and the hypophysis. This is responsible for the formation of an important myelomegakaryocytic focus in a hemorrhagic cyst of the thyroid. In the treatment of this disorder only general routes are possible, and their usefulness is relative. Splenectomy is contraindicated. Irradiation is ineffective. Although a constitutional factor cannot be excluded, megakaryocytic aleukemic myelocytosis seems to be a toxic infectious syndrome of multiple causes.

Book Notices

A Handbook of Psychiatry. By Louis J. Karnosh, B.S., Sc.D., M.D., Associate Clinical Professor of Nervous Diseases, School of Medicine, Western Reserve University, Cleveland, Ohio. With the collaboration of Edward M. Zucker, A.B., M.D., Clinical Instructor in Nervous Diseases, Western Reserve School of Medicine, Cleveland, Ohio. Cloth. Price, \$4.50. Pp. 302, with 40 illustrations. St. Louis: C. V. Mosby Company, 1945.

Dr. Karnosh is associate professor of nervous diseases at Western Reserve University and director of neuropsychiatry, Cleveland City Hospital. Dr. Zucker is clinical instructor in nervous diseases at Western Reserve University and associate in neuropsychiatry at Cleveland City Hospital. As such both men have had extensive experience in neuropsychiatry as clinicians and teachers. The purpose of this handbook, as stated in the preface, "is to function as a faithful delineator of fundamental information on its particular subject and as a stimulating guide to further and more detailed study and investigation." This handbook should succeed in meeting both requirements. The book is well written. The bibliography is good although not very extensive (many excellent papers and books by well regarded writers on dynamic psychiatry have been omitted). Although the book contains only 302 pages including the index, the purpose for which the book was written has been adequately fulfilled. Probably the weakest chapter in the book is the one on psychosomatic medicine, which is finding such a prominent place in medicine today. The authors have ignored much of the research work that has been done in this field during the last decade. The chapters which relate to examination of the mental patient, management and observation of the mental patient and the purely descriptive material of categorical classification are particularly good. The chapters devoted to traumatic psychoses and psychoses with pathologic changes in the brain are also clearly and interestingly written. There is nothing in this handbook that is overtly controversial. Any differences in theory or practice related to different schools of psychiatry are presented without argument. The reader is left to read and arrive at his own conclusions. The book is recommended to students and graduates of medicine for exactly the purpose quoted in the preface.

Deep Massage and Manipulation Illustrated. By James Cyriax, M.D., B.Ch., Assistant Medical Officer, Physiotherapeutic Department, St. Thomas's Hospital, London. Cloth. Price, \$4.50. Pp. 242, with 98 illustrations. New York & London: Paul B. Hoeber, Inc., 1945.

This book deals exclusively with the technic employed and the results obtained from the penetrating effect of friction massage on deep-seated tissues. The technic described is that of deep friction over the site of the lesion, "which may or may not be within the painful area outlined by the patient." Heat is not given preceding this procedure; in fact, the author definitely states that he does not use it. He emphasizes the importance of diagnosis and the utilization of this technic "when a deeply situated soft structure has to have its mobility restored. . . . Hence traumatic or rheumatic lesions—both acute and chronic—of muscle, fascia, tendon, ligament and, sometimes, joint-capsule provide almost the only indications for deep friction."

Dr. Cyriax's method differs from the one used in this country. In the United States circular technic is used with the thumb over the lesion, while his method uses a deep transverse friction by means of the middle and index fingers, largely the middle finger. The purpose of this method is to free adhesions by "the mobilization of tissues in a way that exercises do not achieve."

The book is in two parts. The first part (18 pages) deals with the principles and technic of deep massage and manipulation. There are short chapters on (1) the scope and purpose of deep massage, (2) the principles governing the use of deep massage, (3) position of the physical therapist and her hands, (4) the physical therapist's working day, and (5) the action of massage. Part two (221 pages) has 98 full page plates. Each illustration has a page which describes the nature of the lesion, frequency, indication, the patient's posture, technic, duration of treatment and results. The descriptions are in sum-

mary form, and the illustrations clearly describe the technic. Both are well done.

Undoubtedly there are conditions in which the use of this vigorous technic is indicated; but, as Dr. Cyriax himself warns, there are dangers. "The use of deep friction, since it cannot fail to be painful, is justified only by the fact that it possesses great curative powers when applied to the right spot in the right way. If, then, damage is to be avoided, no question of deep friction can arise until two conditions are fulfilled—the first that the physiotherapist knows how to give it, and the second that she knows exactly where. Thus, the technically competent physiotherapist must be given a diagnosis precise in detail."

Unless the prescribing physician gives a diagnosis that is precise in detail, and the physical therapist knows how to apply the technic to the right spot in the right way, extreme caution should be used in introducing this method because of the danger of aggravating the original condition.

Character-Analysis: Principles and Technique for Psychoanalysts in Practice and in Training. By Wilhelm Reich. Translated by Theodore P. Wolfe. Second edition. Cloth. Price, \$4.50. Pp. 328, with illustrations. New York: Orgone Institute Press, 1945.

This book is an English translation of Reich's book of the same title published in Germany in 1933. As the jacket states, the book is intended for "students and practitioners in psychoanalysis." The book is not recommended to physicians or laymen who are not extremely well oriented in this specialty. There is much in the content of a controversial nature. The author takes a superior, almost condescending attitude toward most psychoanalysts, including Freud, whom he appears to condemn with faint praise. While there may be and probably is valuable material of careful thought and investigation contained in the contents of this volume, the subjects discussed should be strictly confined to serious students of dynamic psychiatry. Other readers will only be confused and bewildered by Reich's scientific jargon.

The Sexual Revolution Toward a Self-Governing Character Structure. By Wilhelm Reich. Translated by Theodore P. Wolfe. Cloth. Price, \$3.25. Pp. 273. New York: Orgone Institute Press, 1945.

This volume, like *Character-Analysis*, represents an English translation of a German production published in 1930. Also, like *Character-Analysis*, this book will prove neither valuable nor even interesting to any one who is not well oriented in psychoanalytic theory and practice. Reich may or may not have some valuable, advanced and constructive ideas. Only time and careful investigation of clinical material will prove whether his deduction, conclusions and what sometimes appear to be fantastic correlations are sound. Like most of Reich's books and papers, this volume is overloaded with "terminology," and even experienced psychoanalysts are liable to get lost in the maze of reichian clichés and attempts at new and original phraseology. The book is extremely confusing, but it is possible that something of value may eventually materialize as a result of Reich's studies. His books, however, are strictly for advanced students.

Psychiatry in Modern Warfare. By Edward A. Strecker, A.M., M.D., Litt.D., Professor of Psychiatry and Chairman of the Department, School of Medicine, University of Pennsylvania, Philadelphia, and Kenneth E. Appel, Ph.D., M.D., Sc.D., Assistant Professor of Psychiatry and Chief of Clinic, School of Medicine, University of Pennsylvania, Philadelphia. Cloth. Price, \$1.50. Pp. 88. New York: Macmillan Company, 1945.

A short, factual and sound statement of the psychiatric problems in modern warfare. The main part of this little volume deals with a comparison of the methods and utilization of psychiatric practice in the two world wars. Etiology, symptomatology, frequency, treatment and prognosis of the main psychiatric conditions encountered in the armed forces are given in a concise and readable manner. It is surprising that full utilization of psychiatry was not made by the armed forces until late in the war. Demobilization with attendant problems are thoughtfully stated in the last third of the book. Many valuable suggestions for physicians, psychiatrists, social workers, employers and others concerned with helping the veteran return to civil life will be found. It is a well written book that gives an epitome of the authors' vast experience and knowledge in a special field of psychiatry.

The Psychology of Women: A Psychoanalytic Interpretation. Volume II: Motherhood. By Helene Deutsch, M.D., Associate Psychiatrist, Massachusetts General Hospital, Boston. Cloth. Price, \$5. Pp. 408. New York: Grune & Stratton, 1945.

This is the second volume of a comprehensive study of the psychology of women by a woman psychiatrist. The author is not only an excellent clinician but possesses great ability in writing of her extended clinical experience. The first volume contains a superior and exhaustive study of the psychological development of women from early childhood to adolescence. Volume II is an equally comprehensive scientific investigation of motherhood. Reproduction with all its psychological, social and biologic aspects is carefully and clearly discussed in simple, easily understandable language. Three chapters at the end of the book are devoted to discussion of psychological problems of unmarried mothers, stepmothers and women who have adopted children. Many well known together with new or rarely recognized dynamic psychological formulations are convincingly illustrated in this work by a wealth of clinical material. The clinical material is so well presented by Dr. Deutsch that the reader has little difficulty in following and agreeing with the correctness of her dynamic conclusions. There is an extensive bibliography and adequate index. Assembling, discussing and formulating this truly scientific treatise was unquestionably a major undertaking. The result is well worth the effort involved.

Cinchona In Java: The Story of Quinine. By Norman Taylor. With an Introduction by Peter Honig. Cloth. Price, \$2.50. Pp. 87, with illustrations. New York: Greenberg, Publisher, 1945.

This is the story of quinine, told in an interesting style by Norman Taylor, known to garden lovers as the editor of the Garden Dictionary and other popular works but equally familiar to those interested in drugs as the director of the Cinchona Products Institute, an organization devoted to the promotion of quinine.

The history of the discovery of the medicinal value of the bark of the various species of the cinchona tree, the attempts to transport cinchona seedlings from Peru into other tropical countries principally by the Dutch and English, the conquest by the Dutch of the extraordinary cultural and genetic problems involved in the propagation of the most productive species, Cinchona ledgeriana, the international trade rivalries for the quinine market and the effect of the introduction of cinchona cultivation on the economic life of Java is a fascinating tale. Unfortunately for romanticists, Mr. Taylor tells us that the familiar story about the Countess of Chinchon is another piece of historical fiction. The antimalarial value of cinchona bark appears to have been first discovered by the Jesuit priests at Lima about 1630. For more than two centuries thereafter the world obtained its cinchona bark from South America. But it soon became evident, particularly to the Dutch and English, that the South American bark production could not keep pace with world demand, particularly since the natural South American cinchona preserves were being ruthlessly stripped without replanting and cultivation. Almost simultaneously both British and Dutch interests initiated cinchona projects. It is a tribute to Dutch perseverance that its efforts were finally crowned with success. Ironically the seedlings that proved to be best were obtained by the Englishman Charles Ledger and bought by the Dutch after the English had refused to take them.

But science is a fickle mistress, and it appears highly probable that atabrine and other newly developed synthetic antimalarials will diminish the importance of Ledger's stock, which is rich in the quinine alkaloid, and enhance the value of the spurned varieties which are abundant in quinidine, cinchonine and cinchonidine. There is little prospect that synthetic quinine or quinidine will have an important commercial influence on the situation.

The author undertakes to discuss malaria and its treatment, but one would never guess from his account that there was anything else than quinine available. It is a question whether the work might not have been a more clever piece of propaganda if the writer had at least given in passing "honorable mention" to atabrine and the critically important role it played in World War II.

There is no question that the Dutch have been handsomely rewarded for their work in making an ample supply of quinine

available to the world. But some believe the reward has been too great and that they have created an essentially evil monopolistic control over an article essential to human welfare. Those who share this point of view, and particularly some of our zealous public prosecutors, owe it to themselves, if they are intellectually honest, to read this able presentation of the case for the Dutch.

Principles of Psychology for the Basic Course in Nursing. By Rev. J. Edward Rault, O.S.B., Ph.D., and Sister M. Maurier Sheehy, R.N.M., B.S., Ph.D., Assistant Professor of Nursing Education, Catholic University of America, Washington, D. C. Cloth. Price, \$2. Pp. 200, with 18 illustrations. Milwaukee: Bruce Publishing Company, 1945.

This small book, by faculty members of the Catholic University, undertakes to provide material to be used as points of departure for discussions in the teaching of nurses. In highly condensed form the authors have endeavored to give a little of the essential material about the nervous system and much more about mental functioning. The result is a brief outline that should meet the purpose the authors intended, that is, as an aid to teachers of psychology. Taken by itself, however, the work has the basic weakness inescapable when those genetic considerations that offer the basis for the understanding of personality structure and human relationships are ignored, as they are by the authors. A nurse really cannot be helped to understand very much about her patient as a human being through a psychology that fails to give a consistent account of the growth and development of the emotional and social life through childhood and of the real life relationships people meet. She may learn quite a few psychological concepts and get some awareness of how people adjust and fail to adjust, but she does not get what the foreword of the book correctly asks for: a psychology with a "soul." This refusal of many psychologists to deal with the simple facts of human existence, of family and social relationships, is understandable in view of traditional taboos and prejudice. The following misstatement (page 124) perhaps makes the point most simply: "Freud and his followers base the development of various personality traits on accidental experiences of a sexual nature in early childhood." No one familiar with the development of dynamic psychology would quote this archaic concept in this form. If the teachers of psychology really wish to teach a psychology invested with "soul," a positive approach to the real life experience of human beings is necessary. This is not offered in the work by Rault and Sheehy.

Illustrations of Bandaging and First-Aid. Compiled by Lola Oakes, S.R.N., D.N. Third edition. Fabrikoid. Price, \$2. Pp. 272, with 300 photographs and coloured supplement. Baltimore: William Wood & Company, 1944.

A valuable textbook for teaching the art of bandaging. Numerous good photographs show clearly each step in the application of bandages to the injured parts of the body. Triangular and roller bandages are thoroughly described. It is regretted that so little mention is made of the use of adhesive bandages, since they enjoy wide use in this country. The sections on shock and first aid in hemorrhage are given in the briefest outline. Mention of the elementary physiology involved would have been both more instructive and more interesting reading. The section on first aid to fractures contains no information on the use of splints, particularly on the improvisation of splints from materials at hand. Photographs showing how to lift patients to a stretcher and the moving of patients are welcomed additions to the new edition.

Clinical Atlas of Blood Diseases. By A. Pinney, M.D., M.R.C.P., and Stanley Wyard, M.D., F.R.C.P. Sixth edition. Fabrikoid. Price, \$5. Pp. 198, with 48 illustrations. Philadelphia: Blakiston Company, 1945.

This edition of the pocket size atlas of blood diseases is a valuable and practical guide for the physician, technician or medical student. There are 48 excellent color plates of the different blood diseases. Opposite each plate there is a concise summary of the known facts on etiology, symptoms, blood findings, diagnosis and therapy. There are four pages on hematologic technique. There is an eight page glossary and index. This book is unexcelled as a small atlas of hematology.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

VITAL CAPACITY

To the Editor:—I am interested in the question of vital capacity, its estimation and its significance. None of the books in my small library seem to contain the necessary information for estimating it. I would appreciate references.

Ray S. Wycoff, M.D., Lexington, Neb.

ANSWER.—The maximum volume of air that can be exhaled after a maximal inspiration is called the vital capacity and represents an estimate of the total air content of the lung. An approximate relationship exists between vital capacity and total height: The vital capacity expressed in cubic centimeters is approximately twenty-five times the height in centimeters for man, twenty times for women, twenty-nine times for athletes and fifteen times for children. The measurement is easily accomplished with an ordinary spirometer. The standing patient is instructed to exhale as much air as he can after he has made a maximal inspiration. The rate of expiration should not be too slow or too rapid. Care should be taken that all the air exhaled goes into the recorder. The nose should be closed and the exhalation should be by mouth. It is important that the test be correctly made, and it must be performed two or three times after the patient is clearly instructed. Accuracy depends on the subject's cooperation and so is in part subjective.

Variations in the same person at different times are more significant than deviations from the standard. Vital capacity can be increased within limits with proper exercises. It is reduced in many diseases, especially those involving the cardiovascular and respiratory systems. It measures the elasticity of the lungs in heart failure and so gives an idea of the pulmonary vein engorgement.

The test is generally used to study the status and the evolution of a case of pulmonary tuberculosis or heart disease but adds little to the record of the symptoms and physical signs. Breath holding time is a simple bedside method of obtaining similar information.

CONGENITAL EXOPHTHALMOS

To the Editor:—A patient has congenital exophthalmos of an extreme degree. His brother, one sister and his mother have the same condition. Is there any one who does corrective surgery for such a defect?

M. A. Shillington, M.D., Montana.

ANSWER.—Any surgery performed for congenital exophthalmos must depend, of course, on the basic condition that is causing the protrusion of the eyeballs. Before a decision is reached as to the advisability of surgery, careful roentgenologic studies of the anterior skull are essential as well as an exhaustive examination of the possible degree of flaccidity of the extraocular muscles. If the correction is to come through surgery on the orbit, such work can be done by any capable neurosurgeon.

OLIVOPONTOCEREBELLAR ATROPHY

To the Editor:—A patient shows strong evidence of the neurologic syndrome designated under the term olivopontocerebellar degeneration. This man of 41 has for the past year been troubled by ataxia of the hands, a cerebellar type of speech defect and a cerebellar type of ataxia. There is no nystagmus and this, I believe, is in keeping with the diagnosis mentioned. The abdominal and cremasteric reflexes are absent, and the patient occasionally has diplopia. These last findings made me consider multiple sclerosis as a possibility, but in addition to the rather late onset the patient's real anxiety about himself in contrast to the typical mild euphoria so common in multiple sclerosis points strongly to a degenerative disorder of the olivopontocerebellar type. His negative spinal fluid findings are also consistent with the latter. I consulted a number of reports on olivopontocerebellar disease; in fact, every available reference in the medical school library. Some of these reports give much detail concerning morbid anatomy, but I can find little about prognosis. Some of the patients lived and apparently avoided serious disability for as long as fifteen or even twenty years, while in other cases the progress of disability was rapid and death occurred in a year or two. Is there any information not available to me on the prog-

nosis in this condition? From the nature of the underlying pathologic condition I do not feel optimistic as far as therapy is concerned and I am merely wondering if any one has any ideas that might be tried more or less experimentally.

Hervey M. Cleckley, M.D., Augusta, Ga.

ANSWER.—This case, no doubt, belongs in the group designated as olivopontocerebellar atrophy. Recently this term has been used to include Marie's ataxia, Sanger-Brown's ataxia and Gordon Holmes ataxia, because each are incomplete forms of one and the same process. This condition is thought to be a hereditodegenerative disease, although sporadic cases are occasionally seen. Pathologically there is atrophy of the inferior olives, the nuclei pontis and their fiber pathways leading through the middle and inferior peduncles into the cerebellum. The symptoms described fit in well with the cases of olivopontocerebellar atrophy or degeneration. The prognosis is poor for cure but not for life. There is no known treatment for this condition.

CONTACT LENSES FOLLOWING CATARACT OPERATION

To the Editor:—Can a young woman who has been operated on for congenital cataracts wear contact lenses without causing harm or injury to her eyes? She wears bifocal lenses at the present time.

Martin F. Crotty, M.D., Cambridge, Mass.

ANSWER.—Ophthalmologists are fairly unanimous in the opinion that contact glasses cannot produce harmful results, with the possible exception of their use by patients with high myopia, in whom the trauma of introducing and removing contact glasses might possibly lead to detachment of the retina. Contact glasses are worn by many younger persons who have been operated on for cataract and are successful in such cases. The unfortunate feature is that seldom can they be worn for longer than four to six hours at a time.

PREMENSTRUAL SKIN IRRITATION

To the Editor:—A woman aged 30 complains of itching over the entire body two weeks prior to and until menstruation is established. There is a slight breaking out between the breasts and on the vulva, also a full feeling and tenderness of the breasts. The patient is well and apparently normal except for slight attacks of asthma due mostly to bleaching substance in washing clothes and occasionally to a few other irritants. Would estrogenic substance be indicated or what treatment is advised?

M.D., Iowa.

ANSWER.—It is probable that the symptoms described are based on an excessive amount of estrogenic substance. Therefore the administration of this material is contraindicated and would probably aggravate the situation. For the same reason androgen may do some good by neutralizing some of the excess estrogenic substance. It would be well to give not more than 200 mg. a month in order to avoid unpleasant side effects.

RADIUM TREATMENT OF CANCER OF THE TONGUE

To the Editor:—Could you give me an idea about the use of radium seeds in a malignant growth on the tongue? What are the statistics, if any?

Paul R. Howard, M.D., Oak Park, Ill.

ANSWER.—Cancer of the tongue can be successfully treated with both radon seeds and radium needles. The scarring produced is minimal, and the function after the treatment is usually much better than that obtained with the more radical surgical procedures. The estimation of dosage and the determination of implantation patterns require some skill, and the best results are obtained by experienced radiologists. Improper techniques may produce bone damage and painful sloughs. Cancer of the tongue frequently metastasizes to the cervical lymph nodes early, and this complication must be watched for and adequately treated at an early stage in each case. The five year salvage for all stages of the disease varies from 26 to 33 per cent in various clinics, and 60 per cent of five year cures has been reported for early lesions measuring less than 2 cm. in diameter. Good results with implanted sources of radiation have been reported by Regaud, Cade, Berven, Hayes Martin, Kaplan, C. L. Martin and others.

INJECTIONS OF DISTILLED WATER

To the Editor:—1. Is the therapeutic use of sterile distilled water approved for intravenous use to replace fluid loss in patients, and if so, what is the maximum safe amount that can be given? 2. If not, what harmful effects might result?

M.D., Pennsylvania.

ANSWER.—1. Therapeutic use of distilled water for intravenous use has never been approved by any agency.

2. The harmful results are more theoretical than real, but there appears to be no basis for preference for water over isotonic solution of sodium chloride. Any condition demanding water probably would demand salt also. One physiologist has taken, by continuous intravenous injection, 500 cc. of distilled water without lowering the blood count below his own experimental error. No subjective effects were noted; there was mild hemoglobinuria. Theoretically there could be hemolysis of injurious degree. The reason this is not more serious is that injected water is promptly mixed with blood, so that the degree of hypotonicity is reduced and hemolysis occurs only at the point of injection. Yet there is still no reason for preferring distilled water unless it might be that emergencies may arise when salt solution is not available. In that case, slow injection of water over a period of time might be done. In general, there is no sense in the suggestion. It is never desirable to reduce a physiologic safety factor if it can be avoided.

COUGH DUE TO ALLERGY

To the Editor:—I have a cottage at a summer resort where the nights are pleasantly cool but where the atmosphere is exceptionally damp; the humidity is often 80 to 90 per cent. Last summer my daughter, now 18 months old, developed a dry irritating cough which lasted until a month, or so after we returned to our regular home. This summer, within a week after moving to the summer cottage, she is again coughing. I am extremely allergic, but the baby has shown no other definite indications of allergy. Can the cough be due to the high humidity? If so, is it probable that this may be an etiologic factor in any serious respiratory trouble, such as bronchiectasis? Is the sensitivity likely to decline in the future? Most of the residents at the resort have no complaint, but now and then some one will come for a short time and leave because of the humidity.

M.D., Illinois.

ANSWER.—A dry irritating cough, present under the conditions described during two successive summers and continuing for a month after returning to the all year round home, is not likely to be due only to high humidity. An allergic basis is more likely. Mild asthma or bronchial irritation may be considered preasthmatic. The following possibilities should be considered: (1) pollen sensitivity (grass pollens and ragweeds); (2) mold sensitivity, either in conjunction with pollen sensitivity or as a primary cause of the allergy; (3) environmental factors present in overwhelming amounts in the summer cottage not in such abundance in the regular home (various house dusts or animal emanations). This last is the least likely of the three possibilities but should be looked for as a possible explanation of symptoms.

CANCER, ARTIFICIAL MENOPAUSE AND LIBIDO

To the Editor:—A married woman aged 35, without children, has been separated from her husband for about three years. Her height is 5 feet 4½ inches (163 cm.) and weight 110 pounds (50 Kg.). Her parents are living and well, as are also 8 brothers and sisters. The patient is the eldest in the family. Her past history is normal: the appendix was removed at 4 years; there was drainage, but a good recovery was made; there was no severe peritonitis. The tonsils have been removed. There have been no pregnancies. The patient's habits are good; neither liquor nor tobacco is used. In December 1944 she had some irregular bleeding; in March 1945 a diagnosis by biopsy was made of carcinoma of the cervix. Radium was used in the standard amount by a doctor in Salt Lake City, who explained to the patient that she would have an artificial menopause and that no children could be had by any subsequent marriage. The patient now complains that she lacks sexual desire, response to her fiancé and so forth and asks whether anything can be done to restore the former normal libido. Is it safe to administer estrogenic substance by needle or by mouth, as ethinyl estradiol or diethylstilbestrol? Would such hormones be likely to restore the feeling of well being and sexual desire formerly experienced?

M.D., California.

ANSWER.—In the normally menstruating woman frigidity and lack of libido constitute a psychologic problem and not an endocrine one. In women from whom the ovaries have been removed, however, the decline in sexual desire may be reestablished through the administration of estrogens. Nevertheless, for this patient estrogens are contraindicated since, as the Council on Pharmacy and Chemistry of the American Medical Association has declared, a familial or personal history of a cancer in the generative organs is a contraindication to the use of estrogens. Estrogens are not directly carcinogenic, as is

the case with certain coal tar derivatives and other compounds, but by stimulating the growth of the sexual tissue they may influence these tissues to develop a malignant condition where there is a genetic tendency toward such changes. The androgens testosterone propionate or methyl testosterone may be administered to such a patient, since these compounds will relieve to some extent the menopausal symptoms and at the same time cause an increase in libido. As a matter of fact, it has been demonstrated that testosterone compounds may increase the sexual desire of many women even with normal menstrual cycles, probably through the enlargement of the clitoris, since this organ responds to androgens. The dosages recommended are 25 mg. of testosterone propionate twice weekly until a response is obtained, and then the dose may be diminished to a maintenance level. Methyl testosterone may then be used to maintain the therapeutic response conveniently; since this material is administered by mouth.

CONGENITAL ANOMALY OF UMBILICAL VEIN

To the Editor:—I operated on a patient recently who had a split in the falciform ligament of the liver; i. e., the round ligament (containing the obliterated umbilical vein), instead of forming the lower free edge of the falciform ligament as it normally does, ran alone from the under surface of the liver to the umbilicus. Above this was an empty gap, and above this was the falciform ligament of the liver. I have been unable to find any references to this rare embryologic defect. Would you be kind enough to help me?

M.D., California.

ANSWER.—In an article by H. L. Trimmingham and John R. McDonald entitled "Congenital Anomalies in the Region of the Umbilicus" (*Surg., Gynec. & Obst.* 80:152 [Feb.] 1945) it is stated that "the umbilical vessels converging at the umbilicus persist, normally, as the two obliterated hypogastric arteries, and the ligamentum teres of the liver's falciform ligament. It is doubtful whether this process is ever subject to pathologic aberration." Other references have not been found which in any way relate to the condition described in the inquiry.

SULFONAMIDES AND TRANSFUSIONS OR INFUSIONS

To the Editor:—Spink's book on the sulfonamides advises against the simultaneous use of the intravenous preparations of the sulfonamides with blood transfusion and parenteral glucose. For how long a period is either of these procedures interrupted if sulfonamide compounds are given intravenously? One hour? Two hours? Also can two different sulfonamides be given to the same patient? Are there any contraindications? For instance, a patient receives sulfamerazine (one or two doses) and then, being unable to get the sodium salt of sulfamerazine, one is forced to use sodium sulfadiazine intravenously on account of the serious condition of the patient.

M.D., Ohio.

ANSWER.—Further experience with the sulfonamides indicates that there is no contraindication to the simultaneous parenteral administration of the sulfonamides with transfusions of blood, plasma and infusions of solutions of glucose and sodium chloride. The original recommendation of not giving the sulfonamide simultaneously with other preparations was a precautionary measure. If patients should experience a systemic reaction there would be some difficulty in ascertaining whether or not it was due to the sulfonamide or to a transfusion or infusion. The possibility still exists that confusion might arise under these circumstances, particularly in patients who may have become sensitized to the sulfonamides.

There is no contraindication to the administration of two sulfonamides as illustrated. Sodium sulfadiazine may be given in place of sodium sulfamerazine. Subsequent doses of any sulfonamide following initial treatment with another sulfonamide should be regulated according to the sulfonamide blood levels.

SULFONAMIDES AND PROPHYLAXIS OF SCARLET FEVER

To the Editor:—Is it advisable to use the sulfonamides as a prophylaxis for contacts of scarlet fever patients?

M.D., California.

ANSWER.—Favorable reports have come from military sources with regard to the use of the sulfonamides for controlling streptococcal infections. Many physicians in private practice use the sulfonamides with prophylactic intent for scarlet fever contacts. Nevertheless patients while on sulfonamide therapy have been known to develop scarlet fever, and there are some resistant types of hemolytic streptococci against which the sulfonamides are ineffective. The question of sensitivity to the sulfonamides may also deserve consideration. For scarlet fever prophylaxis convalescent scarlet fever serum is preferable to the use of the sulfonamides.

TRANSIENT TACHYCARDIA

PROGNOSTIC SIGNIFICANCE ALONE AND IN ASSOCIATION WITH TRANSIENT HYPERTENSION

ROBERT L. LEVY, M.D.
NEW YORK

PHILADELPHIA

AND

BRIGADIER GENERAL CHARLES C. HILLMAN
UNITED STATES ARMY

The rate of the heart varies widely in normal persons and may be increased temporarily by many different causes. Among them are excitement, exertion, pain, the ingestion of food, the drinking of coffee or tea and the smoking of tobacco. Acceleration is observed also in numerous states of disease, such as thyrotoxicosis, infection, shock and hemorrhage.

Transient tachycardia due to emotional disturbance, when the only sign of a disordered cardiovascular system, has not been considered clinically important. No careful analysis of this condition has been found in a survey of the literature. In monographs on diseases of the heart only casual mention is made of it. In the booklet on "Standards of Physical Examination During Mobilization" (MR 1-9), issued by the War Department on Oct. 15, 1942, it is specified that a heart will be considered normal when there is "a pulse rate of 100 or over which is not persistent and not due to paroxysmal tachycardia." However, a registrant is not acceptable who shows "a persistent heart rate of 100 or over when this is proved to be persistent in the recumbent posture and on observation and reexamination over a sufficient period of time." The same criteria are applied to candidates for admission to the United States Military Academy (Army Regulations 40-100, Nov. 16, 1942) and to those seeking a commission in the Regular Army, National Guard, Army of the United States and in the Organized Reserves (Army Regulations 40-105, Oct. 14, 1942).

Quite recently some 5,000 men disqualified for general military service for cardiovascular reasons were reexamined by groups of cardiologists in five large

cities.¹ These examiners, using the Army standards, likewise were not impressed by the importance of a temporary increase in heart rate. In fact, in the report of this study the question was raised as to the advisability of extending the upper limit of the normal range, at rest, from 100 to 120 beats per minute. Because of the lack of specific information concerning the significance of transient tachycardia in terms of the subsequent history, the present analysis was undertaken.

MATERIAL, DEFINITIONS AND METHODS OF ANALYSIS

The same medical records of 22,741 Army officers, which served as the source of material for earlier papers in the series, were used in this investigation. The manner of collecting and preparing the data for statistical analysis has been described in previous publications.²

In this study, transient tachycardia has been the topic of central interest. In particular, its prognostic significance has been appraised, using as criteria the later development of sustained hypertension and of retirement and death with cardiovascular-renal diseases. The experience with transient tachycardia alone has been compared with the corresponding experience with transient hypertension alone, with the two conditions combined and with neither present. A brief note on sustained tachycardia has been included.

By transient tachycardia was meant a heart rate of 100 or over, of sinus origin, which was followed after rest, on any particular examination or at a later examination, by a rate under 100. The highest rate obtained during an examination was recorded. Tachycardia was considered to be sustained when a rate of 100 or over persisted, in the recumbent posture, throughout one examination or in a series of reexaminations made in the course of several days.

By transient hypertension was meant a reading over 150 mm. of mercury systolic or 90 diastolic which was followed, on any particular examination or at a later examination, by a reading below these levels. The highest systolic and diastolic readings obtained in any one of a series, taken at a given examination, were recorded. Sustained hypertension was taken to mean a reading of over 150 systolic or 90 diastolic, persisting throughout one examination, and not followed in subsequent examinations by lower levels.

L.; White, P. D.; Stroud, W. D., and Hillman, C. C.: Transient Hypertension: The Relative Prognostic Importance of Various Systolic and Diastolic Levels, and 128:1059 (Aug. 11) 1945. Levy, Hillman, Stroud and White.³

This is the fourth in a series of papers dealing with "Studies of Blood Pressure in Army Officers."

Dr. John W. Fertig, professor of biostatistics, Columbia University College of Physicians and Surgeons, aided in the analysis and preparation of the material for final presentation.

The work described in this paper was done under a contract, recommended by the Committee on Medical Research, between the Office of Scientific Research and Development and Columbia University.

Cardiovascular-renal conditions, if present, were always included in the tabulation as causes of retirement or death, even though not directly responsible for either. Thus, an officer may have retired or died with such a disorder but not necessarily because of it.

As in the papers to which reference already has been made, the method of person-years was employed in the

TABLE 1.—Experience, in Person-Years, Until the Occurrence of Sustained Hypertension, by Age, According to the Presence or Absence of Transient Tachycardia and Transient Hypertension

Age	Person-Years			
	Without Transient Tachycardia, Without Hypertension	Without Transient Tachycardia, With Hypertension	With Transient Tachycardia, Without Hypertension	With Transient Tachycardia, With Hypertension
25-29	20,007	1,711	1,189	110
30-34	31,101	3,587	1,000	998
35-39	31,125	5,992	2,210	1,578
40-44	29,101	7,702	2,180	1,003
45-49	21,019	8,097	2,171	2,205
50-54	12,325	0,309	1,132	1,778
55-59	5,703	1,073	746	1,108

analysis of the data in order to obtain the proper base from which to calculate the various rates on the usual annual basis. Because the subjects remained in the study for varying periods of time, it was essential that their experience be properly evaluated from entrance into the study until retirement or death, or until the period covered by the study was terminated. Further, the experience of each individual was allocated to the proper age group, since the risks discussed vary with age.

It should be stressed that it is not the number of individuals in any group which forms the base for the calculation of the rates, but rather the units of exposure accumulated by them. In fact, the same person might, at different times, belong to different classification groups with respect to the presence or absence of transient hypertension or of transient tachycardia. Thus, there were some who had neither condition throughout their stay in the study and so contributed

TABLE 2.—Rate of Developing Sustained Hypertension, Disability Retirement Rate and Death Rate with Cardiovascular-Renal Diseases, by Age, for Those Without Either Transient Tachycardia or Transient Hypertension (per Thousand Person-Years)

Age	Rate of Developing Sustained Hypertension	Rate of Retirement with Cardiovascular-Renal Diseases	Death Rate with Cardiovascular-Renal Diseases
25-29	0.1	0.2	0.2
30-34	0.7	0.2	0.1
35-39	1.3	0.4	0.1
40-44	1.7	1.2	0.4
45-49	5.1	3.0	1.3
50-54	7.7	8.7	2.0
55-59	13.4	10.3	1.0

all of their experience to the control group. Others began as controls and later developed transient tachycardia or transient hypertension. Their experience was appropriately allocated to the two corresponding groups. Still others began as controls, later developed one condition and still later developed the other. Their experience evidently was divided among three different categories. Thus, if a man aged 27, who began his experience as a control, developed transient hyperten-

sion at age 38 and transient tachycardia at age 46 and was retired for disability at age 56, he received eleven years' control experience in the proper age group, eight years' experience in the transient hypertension group and ten years' experience in the group with both conditions.

The base for calculating the rates of later development of sustained hypertension is somewhat smaller than that for retirements or for deaths, since the persons who developed sustained hypertension might remain in the study for some time before they retired or died, or before the study was terminated. Obviously, during this time they were not exposed again to the same risk. Although the difference in the number of person-years, because of this circumstance, was only about 5 per cent, it was considered worth while to take it into account in the analysis. The age distributions of person-years, shown in table 1, are appropriate only to calculating the rates of developing sustained hypertension. The appropriate distributions for rates of retirement and of death were, of course, also calculated but the figures are not reproduced here.

CONTROL GROUP

The Rates of Developing Sustained Hypertension, of Disability Retirement and of Death with Cardiovascular-Renal Diseases, by Age, for Those Without Either Transient Tachycardia or Transient Hypertension

TABLE 3.—First Occurrence of Transient Tachycardia, by Age

Age Periods	Number Under Observation Throughout Each Age Period	First Transient Tachycardia	Frequency, per Cent
25-29	3,009	115	3.7
30-34	4,526	201	4.4
35-39	5,000	300	5.1
40-44	5,081	310	5.6
45-49	4,010	210	6.0
50-54	2,675	109	6.6
55-59	1,002	70	6.6

(table 2).—It is apparent that in all three categories the rate increases with age. It is by using these rates as a base that the ratios given in tables 4, 5 and 6 are obtained.

TRANSIENT TACHYCARDIA

First Occurrence, by Age (table 3).—The frequency increases somewhat with age, up to 45; at this point a plateau apparently is reached. The first occurrence of transient hypertension, by age, shows a considerably higher frequency.³ However, the curve of increase is similar, beginning with a frequency of 5.9 per cent in the age group 25-29 and reaching a plateau, with 18.6 per cent, at age 50.

Development of Sustained Hypertension, by Age, According to the Presence or Absence of Transient Tachycardia and Transient Hypertension (chart 1 and table 4).—The relative prognostic importance of transient tachycardia and transient hypertension, with respect to the later development of sustained hypertension, is clearly shown in the curves in chart 1. The lowest curve, representing the control group in which neither condition is present, shows a gradual increase in the rate with age. Both the group with transient tachycardia alone and the group with transient hyper-

3. Levy, R. L.; Hillman, C. C.; Stroud, W. D., and White, P. D.: Transient Hypertension: Its Significance in Terms of Later Development of Sustained Hypertension and Cardiovascular-Renal Diseases, J. A. M. A. 124:1829 (Nov. 25) 1943.

tension alone show much higher rates, as indicated in the two succeeding curves. It is noteworthy that these two trends are approximately at the same level at all ages except 55-60.

The uppermost curve shows the rates for the group with both conditions present. It is in this group that

Chart 1.—Rates of developing sustained hypertension, by age, according to the presence or absence of transient tachycardia and transient hypertension.

TABLE 4.—Total Observed Number of Cases of Sustained Hypertension According to the Presence or Absence of Transient Tachycardia and Transient Hypertension, and the Total Number Expected According to the Rates for the Group Without Either Condition

	Without Transient Tachycardia		With Transient Tachycardia	
	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension
Person-years.....	165,216	27,502	11,883	2,546
Cases.....	400	562	120	233
	400	163.6	40.7	47.1
Ratio.....	1.0	3.4	3.4	7.5

the incidence of later sustained hypertension is highest, the rates at the various ages being from five to eighteen times greater than the corresponding control rates.

The same facts are apparent in table 4, in which the ratios have been calculated by comparing the observed number of cases of later sustained hypertension with the number expected on the basis of the control rates at the various ages. The ratios for transient hypertension alone and transient tachycardia alone are identical, whereas the ratio for the group in which the two conditions are combined is more than twice as high.

Disability Retirements with Cardiovascular-Renal Diseases, by Age, According to the Presence or Absence of Transient Tachycardia and Transient Hypertension (chart 2 and table 5).—The same general trends are shown in chart 2 as were apparent in chart 1. There is a progressive increase in the rates for disability retirement with cardiovascular-renal diseases as age increases.

Again the curves for the group with either condition alone are almost superimposed, and the curve for the group with both conditions present shows higher rates throughout.

The ratios obtained by comparing the observed with the expected number of cases (table 5) bring out again the equal importance of transient tachycardia and transient hypertension. When these conditions are combined, the ratio is about 50 per cent greater than when either condition is present alone.

Deaths with Cardiovascular-Renal Diseases, by Age, According to the Presence or Absence of Transient Tachycardia and Transient Hypertension (chart 3 and table 6).—The death rate with cardiovascular-renal diseases for the group with transient tachycardia alone is not conspicuously higher than for the control group,

TABLE 5.—Total Observed Number of Disability Retirements with Cardiovascular-Renal Diseases According to Presence or Absence of Transient Tachycardia and Transient Hypertension, and the Total Number Expected According to the Rates for the Group Without Either Condition

	Without Transient Tachycardia		With Transient Tachycardia	
	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension
Person-Years.....	166,814	29,207	12,429	10,786
Retirements with cardiovascular-renal diseases				
Observed.....	353	343	83	169
Expected.....	353	186.1	41.6	56.1
Ratio.....	1.0	1.9	2.0	3.0

Chart 2.—Disability retirement rates with cardiovascular-renal diseases, by age, according to the presence or absence of transient tachycardia and transient hypertension.

except at age 55 and over. This is in contrast to the group with transient hypertension alone, in which the rates are decidedly higher at all ages. The explanation for this difference is not evident. Where both conditions are present, the rates are distinctly increased.

The same facts are apparent in table 6. The ratio for the group with transient tachycardia alone is not significant. However, for the group with transient hypertension alone the ratio is significant. When both conditions are present the ratio is greater than when either is present alone, although not significantly so.

Chart 3.—Death rates with cardiovascular-renal diseases, by age, according to the presence or absence of transient tachycardia and transient hypertension. (No deaths occurred in the age group 40-44, in the category with transient tachycardia alone. The first portion of this curve is drawn lightly to indicate that its direction between the two connecting points is unknown).

It should be noted that the total number of deaths involved is relatively small.

Disability Retirement Rates, Excluding Cardiovascular-Renal Diseases, According to the Presence or Absence of Transient Tachycardia and Transient Hypertension.—For the group with transient tachycardia alone, the retirement rate is higher than that for the controls for practically every diagnosis. The reason for this is not clear. It is of interest, however, that the highest rates are for neuropsychiatric disorders and tuberculosis.

TABLE 6.—Total Observed Number of Deaths with Cardiovascular-Renal Diseases According to the Presence or Absence of Transient Tachycardia and Transient Hypertension, and the Total Number Expected According to the Rates for the Group Without Either Condition

	Without Transient Tachycardia		With Transient Tachycardia	
	Without Transient Hypertension	With Transient Hypertension	Without Transient Hypertension	With Transient Hypertension
Person-Years.....	166,844	39,207	12,429	10,786
Deaths with cardiovascular-renal diseases.....	106	106	15	37
Expected.....	106	50.2	11.7	15.0
Ratio.....	1.0	2.1	1.3	2.5

In the group with transient hypertension alone, the ratio with respect to the control rates is 1.1, which is not significant. However, when transient tachycardia is present, either alone or with transient hypertension, the ratios are significant, being 2.1 and 1.3 respectively. The latter ratio is considerably smaller, however, than that observed for retirements with cardiovascular-renal diseases.

Deaths, Excluding Cardiovascular-Renal Diseases, According to the Presence or Absence of Transient Tachycardia and Transient Hypertension.—The ratio for the group with transient tachycardia alone, which is 1.2, is not quite significant. The ratios for the group with transient hypertension alone and for the group with the two conditions combined are both significant, being 1.3 and 1.4 respectively. Even when neuropsychiatric causes are excluded, these ratios are still greater than unity, although no longer statistically significant.

SUSTAINED TACHYCARDIA

There were 327 individuals in whom sustained tachycardia was observed. Their experience after this occurrence was small because they were retired relatively early in their military careers. The average duration of follow-up was only eighteen months, so that rates for the later development of sustained hypertension would have no significance. On the other hand, the experience was sufficient to determine rates of disability retirement and death with cardiovascular-renal diseases. The observed rates were much in excess of those of the control group and of the group with transient tachycardia.

SUMMARY AND CONCLUSIONS

1. A statistical analysis was made of the medical records of 22,741 Army officers to determine the prognostic significance of transient tachycardia noted in the course of annual physical examinations. The same records were used which furnished the source of material for earlier papers in this series. The method of person-years was employed in the analysis.

2. The indexes chosen to demonstrate the influence of transient tachycardia on the subsequent state of health and cause of death were the later development of sustained hypertension, and disability retirement and death rates with cardiovascular-renal diseases.

3. The frequency of transient tachycardia increased somewhat with age, up to 45; at this point a plateau apparently was reached. The frequency was considerably less than that found for transient hypertension.

4. The group with transient tachycardia showed higher rates for later sustained hypertension and for retirement with cardiovascular-renal diseases than did the control group. The rates were similar to those for the group with transient hypertension.

5. In the group with transient tachycardia, the death rate with cardiovascular-renal diseases was not significantly greater than in the controls. This was in contrast to the group with transient hypertension, in which a significant increase was demonstrated. The reason for this difference was not evident.

6. When both transient tachycardia and transient hypertension were present, the incidence of later sustained hypertension was more than twice as great as when either condition was present alone. The incidence of retirements and deaths with cardiovascular-renal diseases was also higher, but to a less pronounced degree.

7. In a small group with sustained tachycardia, the rates of retirement and death with cardiovascular-renal diseases were far in excess of those of any other group considered.

8. Transient tachycardia due to emotional disturbance or some other cause not discernible, like transient hypertension of similar origin, is often a precursor of hypertensive vascular disease. In this respect the two conditions are of equal importance.

LOCAL USE OF PENICILLIN IN
INFECTIONS OF THE EAR,
NOSE AND THROAT

RESULTS OF TREATMENT

FLETCHER D. WOODWARD, M.D.

AND

THOMAS HOLT, M.D.

CHARLOTTESVILLE, VA.

In order to evaluate the local use of penicillin in infections of the ear, nose and throat, a study of a group of patients was begun in February 1945 for the purpose of taking advantage of the seasonal peak in the incidence of upper respiratory infections. The study continued for three months. During this period approximately 500 patients were treated. Of this group the case records were complete enough in 339 to be used for statistical purposes. Cultures were obtained in 403 patients, and these results are also tabulated.

Although the exciting cause of acute rhinitis (the common cold) is generally accepted to be a virus, its effects are relatively transient. It is the activation of a host of pathogenic pyogenic organisms by the virus which produces the many local and remote pathologic processes which constitutes the main problem in the management of upper respiratory infections. Fortunately, the majority of these secondary as well as primary invaders are susceptible to penicillin, and since the drug can be applied topically in most instances in adequate concentrations to be effective, infections of the ear, nose and throat and adjacent structures offer an ideal field for the study of this antibiotic agent. None of these patients received penicillin in any way other than locally, and none received any other chemotherapeutic agent. Only commonly employed symptomatic and supportive measures were used in conjunction with the local use of penicillin.

After study of the meager literature and discussion, it was decided to employ

1. Solutions of 500 units per cubic centimeter of the sodium salt in isotonic solution of sodium chloride as a spray and by drop, since stronger solutions might be irritating and weaker ones were apt to become too dilute after mixing with retained body secretions.

2. A base of a water soluble jelly whose pH would not inactivate the penicillin or disturb the nasal mucosa, 1,000 units per gram

3. Lozenges of an inert base such as lactose, 800 units per lozenge

Methods of application were:

For the ear—Instillation of 5 to 6 drops every two hours during the waking period, allowing the drug to remain in the external canal of the upturned ear for five to fifteen minutes. In some instances gentle, positive pressure was used to force the solution through the tympanum and eustachian tube

For the nose: The spray was used every one or two hours during the waking period for two days, then every three to four hours for two days. The jelly was instilled into the nose at bedtime in some instances

For the sinuses: If lavage was indicated, isotonic solution of sodium chloride was employed and 2 to 5 cc. of the solution

or water soluble base jelly was instilled through the cannula at the completion of the irrigation.

For the throat: Lozenges were allowed to dissolve slowly on the tongue every one or two hours. In many instances the nasopharynx and pharynx were sprayed with the solution at the same time, either transnasally or transorally.

For the mouth and gums: The lozenges alone were used

All material was kept under refrigeration until given to the patient, and repeated bacteriologic testing showed no deterioration in the product while under refrigeration and no deterioration at room temperature within the period it was to be used by the patient. The amounts dispensed were solutions in 30 cc. bottles, lozenges in vials of twelve and water soluble jelly in collapsible tubes of 16 Gm. For office use the solution and jelly were kept under refrigeration in sterile rubber-capped bottles.

RESULTS

Acute Rhinitis.—Since acute rhinitis (the common cold) is the activator of most infections in this field, a small group of patients were selected who were seen

12.	1	1.1

during the prodromal or early phase of the disease and whose critical evaluation of the remedy could be relied on. The results obtained in this small group are considered to be encouraging, since the great majority of them (36) believed themselves definitely improved, against 4 who were unimproved in forty-eight hours. None of these 36 developed any complications and all were well within four to five days. It must be remembered that it is important to differentiate an early acute rhinitis from allergic rhinitis and the initial coryza of certain infectious diseases. This differentiation is not always easy in the early phases of these disorders. Acute rhinitis also varies widely in intensity and duration of symptoms, and the psychologic effect of a new drug must also be evaluated in one's conclusions. Hence, until penicillin becomes plentiful enough to treat large groups in army camps and industrial organizations, it cannot be said that topical application in the early phase of acute rhinitis will or will not be of value.

Sphenothmoiditis.—Under this category were grouped those patients in whom the nasal symptoms of a stuffy nose and postnasal discharge, along with

From the Department of Otolaryngology, University of Virginia Hospital

The lozenges were prepared by the Hinson, Westcott & Dunning Company, Baltimore

Paper published under the auspices of the Section on Laryngology, Otolaryngology and Rhinology.

The penicillin used in this study was furnished by the Commercial Solvents Corporation, Terre Haute, Ind.

The bacteriologic studies were conducted in the Clinical Laboratory, University of Virginia Hospital, under the direction of Dr. W. E. Bray

various other commonly related symptoms, persisted after the acute phase of the infection had passed. These symptoms usually persist for three to six weeks before resolution and may be caused by unusual virulence of the organisms, poor body resistance from any cause or certain deformities of the nasal passages producing mechanical obstruction to proper aeration and drainage. Any one or combination of the foregoing tends toward chronicity of the infection. Of the 39 patients in this group, 32 were improved in forty-eight hours and 7 were unimproved.

In order for penicillin to be effective, we must be able to apply it frequently in adequate concentration to the diseased area, so nasal congestion must be relieved intermittently by a spray of 1 per cent ephedrine in isotonic solution of sodium chloride or 0.25 per cent neosynephrin solution. The patient was instructed to spray the nose with the vasoconstrictor solution three times at three minute intervals every three or four

hours, if necessary. In cases in which there is obstruction to aeration and drainage by deformities of the nasal septum or turbinates or in which the infecting organism is penicillin resistant, one cannot expect improvement.

Sphenothmoiditis, Chronic.—In this category were grouped those patients in whom the postnasal discharge had persisted for a longer time. Associated symptoms were nasal stuffiness, occasional headache, cough, sore throat and hoarseness. Pathologic changes characterized by hyperplasia of the nasal mucosa, proliferation of lymphoid tissue in the nasopharynx and pharynx, and mild lymphedema were frequently noted; likewise, nasal obstruction to aeration and drainage from deformities of the nasal septum and turbinates was often present. The other sinuses in this group were not involved.

The results in a small group of 20 patients were 7 improved in four to five days, 13 unimproved. In an effort to secure a more intimate contact of the penicillin solution to this area, 9 patients were treated daily by the Proetz displacement method. Of this number 5 were improved in eight days, and 4 were unimproved. Persistence in this method should be of value in suitable cases. But for reasons just stated, one should not expect a too favorable response in this group.

Acute Maxillary Sinusitis.—The most frequent complication of nasal infection which calls for active surgical intervention is empyema of the maxillary sinus.

It has been our custom for some years to irrigate the maxillary sinus every second or third day with a canula introduced through one of the natural ostiums, or pars membranacea, using isotonic solution of sodium chloride, whenever this condition is recognized. This procedure is painless, hastens resolution and does not

interfere with the normal physiologic response of the nasal or sinus mucosa. As a result of this experience, resolution could formerly be expected in fourteen to twenty-one days.

Since this sinus is so readily accessible and so frequently involved, it offered an excellent opportunity to test the effects of penicillin when injected after the completion of the lavage. For this purpose 2 to 5 cc. of the solution or 2 to 5 cc. of the water soluble base jelly was used. As a result, of 73 patients so treated, 64 were well after an average of 2.7 irrigations, 6 were improved after 4 to 5 irrigations, and 3 were unimproved after 4 to 9 irrigations. In the 64 patients who were well after 2.7 irrigations, the time interval was six to eight days, a very definite decrease in the time interval and number of irrigations. No further reduction in time should be expected, since six to eight days are necessary for the body defenses to be mobilized and for reversal of the pathologic changes. The fact that penicillin is effective in the presence of pus gives it precedence over the sulfonamide drugs in this condition.

Chronic Maxillary Sinusitis.—The same procedure was carried out in 8 patients with chronic maxillary sinusitis. None were improved after 10 irrigations. This result was not unexpected, for the pathologic changes here were irreversible and surgery is required. However, we have found that healing is promoted after operation by instillation of a penicillin solution.

Acute Pharyngitis and Nasopharyngitis.—The acute sore throat is a common disorder and, although usually self limited, serious complications are always imminent.

The infectious process tends to spread rapidly over the mucous membrane, and in many instances the process is more severe in the nasopharynx than in the pharynx, although the symptoms are mainly pharyngeal because of the mobility of the tissues. The nasopharynx should always be inspected under these conditions.

Both lozenges and the spray were used, and if the patient was unable to spray the nasopharynx trans-orally he was instructed to use the nasal route. Of the 31 patients in this group, 27 were improved in forty-eight hours, 3 of whom relapsed and the treatment had to be started again; 4 were unimproved.

It must be remembered here that many persistent sore throats with regional adenitis and elevated temperature are probably of virus origin, infectious mononucleosis being an example of this type. None of these disorders would be affected by penicillin. However, in a few instances of infectious mononucleosis in which there was a pronounced ulcerative pharyngitis the

topical application did seem to control the secondary invaders and hasten healing of the pharyngeal and nasopharyngeal lesion.

Acute Tonsillitis.—Lozenges alone were used for 9 patients; 7 improved within forty-eight hours, and 2 were unimproved. The oral spray was used for 13 patients; 9 were improved in forty-eight hours, and 4 were unimproved. For subacute tonsillitis 6 patients were treated by lozenges alone. Of this small group 5 were improved in three days and 1 was unimproved. Acute tonsillitis is also a self limited disease, as a rule, but the toxemia is severe and complications are not uncommon. The treatment with penicillin is simple and seems to be effective.

Otitis Media, Purulent Acute.—The great majority of acute otitic infections are due to penicillin susceptible organisms, but there is no safe nor practical way to apply the drug to the mucosa of this area. However, 31 patients were treated by the use of drops and in a few instances by gentle positive pressure irrigation; 18 were improved in five to seven days and 13 were unimproved, which is approximately the result one would have obtained without any treatment. The results of systemic treatment by the sulfonamides and penicillin so far overshadow any other method of therapy that the use of penicillin locally is unnecessary and futile.

Otitis Media, Purulent Chronic.—If the causative infection is due to penicillin susceptible organisms and there is a large tympanic perforation, without pseudo-cholesteatoma or osteitis, then local treatment may be employed. Instillation of drops was used for 34 such patients; 18 were improved in seven days, and 16 were

unimproved in seven days. Under these conditions we feel we are justified in trying local treatment. One of the most gratifying yet unexpected results in this group of patients was the disappearance of the odor. Since the odor is due, as a rule, to penicillin resistant organisms, one can only conjecture as to the reason for this unexpected result. In several cases due to gram positive cocci, it was noted that following treatment these organisms disappeared and their place was taken by one or more of the gram negative bacilli. This

change of flora did not mean the cessation of drainage and clinical cure but oftentimes an even more intractable infection.

Postoperative Radical Mastoid Cavities.—Following radical mastoidectomy, we used the drops locally for 18 patients. Within seven days 13 were improved and 5 were unimproved. In some instances a catheter was sewed into the depths of the wound through the incision and connected with a 50 cc. syringe fastened to

the bed post. A closed method of irrigation was thereby established. These wounds all remained clean as long as this procedure was maintained. When the patient was allowed out of bed after four to five days, the tube was withdrawn and the local instillation of drops was started. The cases listed as improved were those in which there was but little infection, and healing was rapid. Reinfection in old, healed, radical cavities usually respond quite well to the same treatment, provided the organisms are susceptible.

Vincent's Gingivitis and Angina.—A small group of 8 patients with proved Vincent's infection of the gingiva, mouth or pharynx were treated by the frequent use of the lozenge. All were improved in three to five days. One of the most gratifying findings here was in those cases of gingivostomatitis in which the severe symptoms were promptly alleviated, the patient being able to eat fairly comfortably in twenty-four hours. Proper medical and surgical treatment was, of course, also employed.

Toxic or Allergic Reactions.—No systemic toxic nor allergic reactions were noted in this series. However, in 6 patients under treatment for otitic infections, a pronounced dermatitis of the auditory canal and auricle occurred, and treatment had to be discontinued. Whether this reaction was due to local sensitization

or to the release of certain penicillin resistant organisms whose activity had formerly been held in abeyance was undetermined.

CONCLUSION

The local use of penicillin has proved helpful in the control of acute and subacute infections of the nose, sinuses, nasopharynx, pharynx and mouth and of occasional benefit in certain cases of chronic otitis media. It has also proved beneficial postoperatively in mastoid and sinus surgery.

It has been of no value in acute otitis media and of no or negligible value in chronic sinusitis and chronic sinusitis associated with allergic rhinitis.

Its usefulness in the treatment of the common cold is still undetermined.

In those cases in which it has proved beneficial, its effect will no doubt be enhanced by its combined use systemically or by the combined use of an appropriate sulfonamide.

Local application does not produce any dramatic change in the bacterial flora present in the nose and throat. Its effect seems to be more bacteriostatic in nature than bactericidal. In several patients who had recently recovered from scarlet fever, we were unable to alter the bacterial flora on repeated cultures, after local treatment.

The solution, 500 units per cubic centimeter, and the lozenge provide the simplest and most effective means of application. The water soluble jelly was useful at times for instillation into the nose at bedtime and in the treatment of atrophic rhinitis, in which the nasal symptoms were ameliorated.

We are hopeful that new antibiotics will soon be available, particularly for the gram negative organisms and for the more common bacteria which have become sulfonamide or penicillin resistant.

104 East Market Street.

ABSTRACT OF DISCUSSION

DR. ARTHUR W. PROETZ, St. Louis: This careful study and cautious evaluation of the local effects of penicillin goes far to clarify the problem and should prevent useless medication. A new therapeutic agent should be studied by capable observers under scientific conditions and with adequate controls rather than be turned loose on practicing physicians, who, honest though they may be, are untrained in scientific methods and flood the literature with unimportant communications. By the time the effect of these misleading opinions has been brushed away months have passed and tons of useless medicaments have been administered. My own experience with penicillin, much less extensive than that of Dr. Woodward and Dr. Holt, is limited to its effect on the nose. It would suggest that penicillin may be of some minor help in the control of acute and subacute infections of the nose. I am not at all convinced either by my own observations or by those in the present paper that this therapeutic value is any greater than that of half a dozen other agents at hand. The common cold, for example, should improve under almost any treatment within the thirty-six to forty-eight hours stipulated in table 1; a small number will improve without any treatment in that time. The results of my own introduction of penicillin solution (250 units per cubic centimeter) were disappointing, as were those of Dr. Woodward. Almost any of the commonly used solutions should produce some improvement in a chronic sphenoiditis within eight days. Whether this is permanent or not depends on the nature of the pathologic process in the sinus and not on the irrigating solution. The concentration of 250 units per cubic centimeter in my own cases was determined by my previous observations in the laboratory that stronger solutions had some slight detrimental effect on the ciliary activity. The effects of the local application of penicillin on the upper respiratory tract closely resemble those of a great number of other topical applications.

DR. O. E. VAN ALYEA, Chicago: The authors recognize that to be effective penicillin must be of sufficient concentration and in constant contact with the infected tissues for a considerable time. This no doubt accounts for the very good results obtained in their cases of pharyngitis and tonsillitis with the constant use of lozenges augmented with nasal and pharyngeal sprays. Penicillin was shown to be less effective in treatment of nasal and sinus infections, and this is easily understood when it is realized that no medicament remains long in contact with the ciliated mucosa of the nose and sinus because of the protective nature of the mucous film which lines these cavities and the action of the cilia, which quickly propels foreign material to the sinus outlets and to the nasopharynx. The authors found the penicillin drops to be of little value in the treatment of acute otitic infections. Although 18 of the 31 cases showed improvement in seven days, similar or better results have been attained by the use of other cleansing agents. In the chronic suppurative ear cases the use of the drops was also disappointing but was found to be of distinct value in eliminating the odor from the discharge. Following mastoid surgery, penicillin instilled by way of a catheter kept in the wound maintains a clean field and in that respect is of distinct value.

DR. C. H. McCASKEY, Indianapolis: Considering the fact that penicillin is practically a new drug and that the time was so short in which the authors had to carry on their experiments, and especially with the small amount of work that had been done by other investigators, these doctors had to depend entirely on their own findings and methods of procedure. Some of the important points which they made in this discussion are as follows: 1. They attempted to keep a fairly normal pH for their spray solution, which is important in any solution used as a nasal spray. 2. They advised adequate doses and the frequent use of their solution in nasal infections. 3. They pointed out that in acute purulent maxillary sinusitis the drug was effective but that in chronic maxillary sinusitis the results were not good. 4. They brought out the point that in virus infections the drug was not of much value but that in many of the secondary infections following virus infections it was valuable. 5. They stated that their results in acute and chronic purulent otitis media were not of great value. My experience with penicillin in infections of the ear, nose and throat has been limited.

ARTHRITIS RESEMBLING REITER'S
SYNDROME

OBSERVATIONS ON TWENTY-FIVE CASES

CAPTAIN JOSEPH L. HOLLANDER
CAPTAIN CHARLES W. FOGARTY JR.
CAPTAIN NATHAN R. ABRAMS
AND
MAJOR DAVID M. KYDD
MEDICAL CORPS, ARMY OF THE UNITED STATES

At Ashburn General Hospital, a center designated by the Army for the treatment of arthritis, we have had the opportunity of seeing many unusual manifestations of rheumatic disease. We have been impressed by the apparent frequency of a syndrome characterized by arthritis, nonspecific urethritis and often conjunctivitis. Because of the sparsity of previous clinical reports, we believe it advisable to report our preliminary observations.

In 1916 Reiter¹ described a clinical syndrome with these characteristics. Since that time only 50 cases in twenty-six communications have been reported, and only a few of these reports have appeared in American journals.² It is noteworthy that 22 of the reported cases have occurred in soldiers on active duty in World Wars I and II.

Various organisms, including a spirochete, a staphylococcus, an enterococcus and a filtrable virus, have been suggested as causal agents, but none have been confirmed, and the symptom complex still remains a syndrome of undetermined etiology. In 1942 Bauer and Engelman,³ in reporting 6 cases, described the results of a biopsy of synovial membrane in 1 case and reported findings suggestive of infectious disease, but distinct either from the ordinary specific infectious arthritides or from rheumatoid arthritis. Other reports have disclosed that the entire triad has not always been present, and, in some, other symptoms including diarrhea, balanitis and nongonorrheal keratoderma have occurred.⁴

Our series consists of 25 cases, in 11 of which the triad of arthritis with an acute onset, purulent urethritis and suppurative conjunctivitis occurred. The remaining 14 cases presented an identical clinical pattern except that the conjunctivitis was absent. For the sake of comparison and discussion, those with the entire triad are listed as "typical" (group 1) and the others as "atypical" (group 2).

The patients came from all branches of the Army, and the disease appeared in camps in the United States as well as in all the major theaters of operation. Necessarily many of our observations include those recorded at other military installations. There were 9 officers in the series. Ages varied from 18 to 37 years, with an average of 26 years. Although many of our patients

are nurses, Red Cross workers and members of the WAC, no case resembling this syndrome was observed in the female sex. Only 2 patients gave a positive family history of rheumatic disease. None gave a history of previous joint disease other than a few cases of definite traumatic arthritis. None of the patients in group 1 admitted sexual exposure within one month preceding the onset. Five patients in group 2 gave such a history. The results of other observations are given in the table.

Urethritis was the initial symptom in 19 cases, arthritis in 2 and diarrhea in 4. The time required for the complete clinical picture to develop varied from two to forty-two days, with an average of fifteen days. In those cases in which arthritis was the initial symptom urethritis developed within three days.

The urethritis was purulent in nature. Repeated smears and cultures of the discharge were negative for gonococci. The urethritis did not appear to be influenced significantly by adequate doses of the sulfonamides (23 cases) or penicillin (19 cases) in doses of 100,000 to 3,000,000 units. In practically all cases, however, it disappeared eventually, but recurrences were noted in a few. In 4 cases a residual prostatitis

was noted. In these, culture of the prostatic secretion on selective mediums showed either no growth or *Staphylococcus albus*.

Eight cases showed a balanitis or perimeatal ulceration. Dark field examinations in these cases were consistently negative. A recurrence of balanitis was noted in 2 cases.

A mild diarrhea of short duration was the initial symptom in 4 cases and was concomitant with the arthritis in 2 others. Stool examinations and cultures revealed no specific organisms.

Purulent conjunctivitis developed either just before or shortly after the onset of the arthritis in 11 cases. This was usually mild and disappeared as promptly on symptomatic therapy alone as when a sulfonamide or penicillin was administered. It lasted from two days to three weeks, an average duration of four days. Cultures of the discharge were either sterile or showed a scant growth of *Staphylococcus albus*.

Concurrent with the acute phase of the syndrome, circinate lesions developed on the penis in 1 case and keratotic lesions on the legs and feet. The penile lesions were typical of balanitis circinata. The skin lesions were characteristic of keratoderma blennorrhagica and lasted two months. In another case subungual abscesses appeared in six of the fingers.

4. Lever, W. F., and Crawford, G. M.: Keratosis Blennorrhagica Without Gonorrhea (Reiter's Disease?), *Arch. Dermat. & Syph.*, 40: 389 (June) 1944.

Characteristic of the entire group was the explosive onset of an acute polyarthritis accompanied by a moderate elevation of temperature. The chill which so often initiates acute specific infectious arthritis was significantly absent in every case. The affected joints were red, hot, swollen and tender. The involved joints are shown in figure 1. Noteworthy is the fact that many of these cases were initially regarded as either acute rheumatic fever or gonorrheal arthritis.

During this acute stage the leukocyte count averaged 12,000 per cubic millimeter. The sedimentation of the erythrocytes was rapid in all cases. The peak was not reached until approximately four to six weeks after the onset of the arthritis, when the urethritis and conjunctivitis had subsided and the inflammation of the joints was less acute.

In 8 cases a joint was aspirated. The fluid contained from 9,000 to 14,000 leukocytes per cubic millimeter, of which 65 to 74 per cent were neutrophils. Smears were negative and cultures on routine and

cytosis disappeared within seven to ten days. The sedimentation rate returned to normal in approximately three months in most cases.

The duration varied. Some patients became asymptomatic in three months; others still under observation have symptoms after eight months. The average dura-

Fig. 1.—Distribution of joint involvement by case numbers.

selective mediums were sterile. Gonococcus complement fixation reactions on blood and synovial fluid were negative in the 3 cases in which the test was employed.

Roentgenographic abnormalities were noted in 18 cases. These changes first appeared approximately two months after the onset of the disease. Osteoporosis of the bone ends was the characteristic finding. Often this was spotty, and never was it sharply defined. In addition, periosteal proliferation developed in 3 cases. Subsequent roentgenograms in 2 cases showed a disappearance of this. Actual bony destruction in a small joint was noted in only 2 cases.

The clinical course showed little variation except for the total duration of the disease. As a rule, the acute stage lasted from four to six weeks. In only 1 case was there further progression to new joints after this time. Following the acute stage, most joints returned to normal. In many, however, a few of the most severely affected joints continued to be swollen and stiff without signs of acute inflammation. Fever and leuko-

Fig. 2.—Synovia from the suprapatellar pouch, left knee; $\times 60$.

tion in 6 patients who returned to duty was five months. Recurrences of joint swelling and pain were encountered in 7 patients. Three patients gave a history of a previous attack of the symptom triad followed by complete remissions of nine, sixteen and twenty-nine

Fig. 3.—Synovia from the infrapatellar fat pad; $\times 60$.

months respectively. Unilateral superficial keratitis developed during the course of the disease in 2 patients who had had an early conjunctivitis and in 1 who had had no previous ocular abnormalities. One patient without previous eye symptoms developed a moder-

ately severe iritis. No permanent ocular damage was encountered.

An arthrotomy was performed on the right knee of 1 patient in the eighth month of his disease. The synovia was congested and presented a reddish purple appearance. No gross thickening was noted. There were several small circumscribed areas of white fibrinous-like material lying on the surface of the synovium. Portions of synovia from the floor of the suprapatellar pouch just proximal to the articular surface of the condyle and from the congested infrapatellar fat pad were removed for section. The cartilage appeared normal.

Microscopic examination revealed intense inflammatory reaction, which was limited to the superficial synovial layers and did not involve the supporting collagen, fibrous connective tissue or vessel walls (fig. 2). The synovium was thrown into large club-like projections in which the abundant capillaries were all dilated. Each projection was distended by a heavy lymphocytic infiltrate mixed with a smattering of plasma cells and a few neutrophils. No fibrinous exudate was observed. The intima was approximately six to ten layers deep. Only a few perivascular focal collections of lymphocytes and plasma cells could be found. There were no well defined new capillaries, and the intense hyperemia consisted of dilatation of preexisting capillaries (fig. 3).

On the basis of our observations we believe that Reiter's syndrome may exist even when the triad of arthritis, nonspecific urethritis and suppurative conjunctivitis is incomplete. In our series conjunctivitis was commonly absent.

We believe, moreover, that this disease is a clinical entity. It differs from the acute specific infectious arthritides in many respects. The course in practically all our patients has been that of a self-limited disease without residual damage to any body structure in spite of the lack of definitive therapy. Prior to the use of sulfonamides and penicillin, no group of patients with acute specific infectious arthritis had such a favorable prognosis. Recurrences such as occurred in our patients are not characteristic of specific forms of arthritis. The initial rise of temperature, white blood count and the synovial fluid cell counts were considerably lower than are commonly observed in the specific types. Response to chemotherapy was lacking.

Differentiation from rheumatoid arthritis is more difficult clinically. The association of nonspecific urethritis with or without suppurative conjunctivitis is not common in the latter. Furthermore, recurrences of such a triad have not been described in rheumatoid arthritis. While a biopsy was taken of only one joint in our series, the findings were similar to those in the case reported by Bauer and Engleman even though it was performed later in the course of the disease. The intense hyperemia and cellular reaction, limited to the superficial layers of the synovium, was quite striking and distinctly different from the appearance in rheumatoid arthritis.

CONCLUSION

From our observations in 11 cases of polyarthritis, nonspecific urethritis and conjunctivitis, identical with those described previously as the Reiter syndrome, and 14 cases similar to this group except for the absence of conjunctivitis, we believe that these two groups are similar and that they represent a clinical entity distinct from specific infectious arthritis or rheumatoid arthritis.

THE COMING AGE OF INDUSTRIAL MEDICINE

LEONARD G. ROWNTREE, M.D.

Colonel, Medical Reserve; Chief, Medical Division, National Selective Service System; Chairman, Joint Committee on Physical Fitness
WASHINGTON, D. C.

Industrial health in wartime is a very critical aspect of our whole national manpower problem. Wartime taught us that the resources of human capacity are the greatest resources in any country. We started out in 1940 to train 900,000 men a year in a peacetime military training program. That was easy to accomplish, and our manpower seemed completely adequate for such a purpose. We have learned, as a result of our experience in the war, that our manpower is neither inexhaustible nor is it always available. We cannot waste or neglect it. On the contrary we must carefully nurture, husband and train it and wisely allocate and employ it if we are to achieve our national purposes. It has been the function of the Selective Service System and the War Manpower Commission to supervise this utilization of manpower and to bring sharply to mind its problems in wartime which may be a guide to our postwar needs.

TABLE 1.—Analysis of the Total Manpower Situation,
Jan. 1, 1945

Total population	138,000,000
Total male population.....	69,000,000
Total number of registrants 18-45 years of age.....	45,000,000
Total number of registrants 18-44 years of age.....	29,000,000
Total number of registrants 18-37 years of age.....	22,000,000
(liable for military service)	
Total number of registrants who have been in armed forces..	10,700,000
Registrants 18-37 years of age rejected for service.....	4,500,000
Registrants 18-37 years of age in other classes.....	6,800,000

One of the early outstanding problems was the significance of the health and fitness of individuals. This was brought sharply in relief as the military authorities indicated that older men were not equal to the onerous duties of battle and the demand for younger men mounted. With all the conflicting needs of manpower for combat and war production and for food and with goals that would have been in ordinary times impossible to meet, it may be recorded that the handling of the manpower program was adequate for the situation. We raised an Army and Navy of 12,000,000 men. We had a labor force of more than 50,000,000 men and women, and the final test of the success of the manpower problem was the victory both in Europe and in the Pacific.

SIZE OF THE MANPOWER PROBLEM

Some statistics will indicate the size of the manpower problem with which we were dealing in wartime. The situation on Jan. 1, 1945 was as shown in table 1.

THE MILITARY MANPOWER PROBLEM

Military manpower needs were determined and they were effectively supplied. Selective Service procured registrants of military age and sent forward to the induction stations, with or without examination, those believed capable of service. The armed forces induction

Paper to have been presented before the Annual Congress on Industrial Health, Chicago, Feb. 13, 1945.

In the preparation of this paper assistance was given by Col. Edward A. Fitzpatrick, A. U. S., Col. John N. Andrews, Infantry, Col. William M. Wilder, Infantry, and the Division of Research and Statistics of the Selective Service System.

stations made physical examinations and inducted into the service those men not deferred and considered physically, mentally and morally fit. The armed forces gave all basic and other forms of training prior to combat, discharged on Certificates of Disability all those found inapt or adjudged unfit, accorded to all members of the fighting forces the finest medical service that this country could provide, rehabilitated defects on an unprecedented scale, considered assignments judiciously and as far as possible utilized manpower to best advantage. Thus the military authorities were able to build the finest fighting force in history from the manpower available in the nation. But, in doing so, Selective Service and the armed forces uncovered some national weaknesses of which the nation and we, as doctors, must take cognizance.

TABLE 2—Estimated Principal Causes for Rejection of Registrants 18-37 Years of Age in Class 1-F and Classes with F Designation* April 1, 1945

Principal Cause for Rejection	Number			Per Cent		
	Total	White†	Negro	Total	White†	Negro
Total..	4,629,000	3,713,000	886,000	100.0	100.0	100.0

* Includes registrants in classes 1A, B and C with F designation.
† Includes all races other than Negro.
‡ Includes (1) registrants with more than one disqualifying defect who were rejected for educational deficiency prior to June 1, 1941, (2) registrants rejected for failure to meet minimum intelligence standards beginning June 1, 1941 and (3) morons, imbeciles and idiots rejected November 10, 1941.

REJECTION OF REGISTRANTS BY CATEGORY AND NUMBER

Table 2 gives in broad categories the number of rejections as of April 1, 1945. While the rejection rate is a less reliable index of the national health picture than is the incidence of defects, yet it gives some insight of our shortcomings in health, at least from a military point of view. The table shows that the number of rejections in the IV-F pool is 4,629,000 as of April 1, 1945 and also reveals the causes for these rejections. Medically, rejection does not mean that these four and one-half million men are cripples but rather that they are below military requirements. The standards, how-

1. This paper was for a February 1945 meeting, presented on request and brought up to date.

ever, have been investigated thoroughly by a Presidential commission and are considered rock bottom from a military point of view.

THE CIVILIAN MANPOWER PROBLEM

Like "taxes," the civilian manpower problem is with us always both in peace and in war. In war it is especially difficult, because if we take men out of the civilian labor force and put them in the Army we increase the demands of civilian labor force to arm, clothe, feed and maintain these men as soldiers. The constantly fluctuating and unsettled conditions of wartime adds to the problem, factors which do not exist in peacetime.

The size and composition of the labor force for 1942, 1943 and 1944 and the distribution of working personnel is indicated in table 3. From the table it appears that as men in industry decreased in number from 37,610,000 to 34,060,000 the number of women increased by more than 2,000,000, from 16,020,000 to 18,150,000. The additional million is probably made up largely from the ranks of the previously unemployed.

PROBLEM OF RURAL INDUSTRIAL MANPOWER

The problem of industrial manpower has been evident in the country as in the city. The problem has become no less important in wartime as in peace. It becomes more important in view of the diminishing labor force on farms. Many expedients were developed to spread the regular labor force on farms from cities by the crea-

TABLE 3—The Labor Force, 1942, 1943 and 1944

	December 1942	December 1943	December 1944
Labor force	57,610,000	51,060,000	52,210,000
Men	37,610,000	34,060,000	34,060,000
Women	16,020,000	17,000,000	18,150,000
Agricultural	7,180,000	6,800,000	6,110,000
Nonagricultural	14,840,000	10,200,000	12,040,000
Unemployed	1,000,000	800,000	600,000

Nonagricultural employment includes mining, construction, transportation and public utilities, government, finance, service, trade, manufacturing and miscellaneous.

tion of women land armies and by special training methods and provision of transportation of itinerant workers. The same problems exist for the farm as for the factory. The problem of health and fitness was as significant in the country as in the city, and there was no superiority in the physical fitness of farmers as compared with industrial workers. The farmer and the food processor have met the demands of our civilian and military manpower as has the industrial worker.

A SUMMARY VIEW OF THE WARTIME INDUSTRIAL HYGIENE PROBLEM

Industrial health, including the health of the agricultural workers, is an important phase of the wartime manpower problem. We have not thought of it in such terms, but it was there all the time. The military manpower had the spotlight. But the no less necessary but less spectacular war and food production were progressively required to reach extraordinary goals not only with less manpower but with a manpower less physically fit. The process of selection selected the physically fit (I-A) and left those not fit for military service (the IV-F's). There was a further fact of great significance that great numbers of doctors and dentists entered the military service, and the industrial and agricultural population lacked adequate medical care according to peacetime standards.

ANTICIPATING POSTWAR PROBLEMS

In the postwar world this problem of industrial health will be even more significant. There will be cutbacks, frictional unemployment and reconversion. There will be the necessary readjustments. There will be more than 10,000,000 returning from the armed forces, many handicapped. There will also be the need of the readjustment of the medical and dental professions, not only to care for the civilian population, but to care for the hospitalized veterans of the war.

INDUSTRIAL EMPLOYMENT CONDITIONS

During war, manpower engaged in industry was characterized by high rates of turnover and absenteeism. Several factors contributed to the cause. Men moved by a spirit of adventure want to "go places and see things" and hence take advantage of every opportunity for change. The more shiftless avoid work completely as their finances permit. Many war workers live in mushroom settlements which are low in sanitary provisions and in medical and dental facilities. But, above all else, the greatest difficulty is found in the ranks of the workers themselves. Though many in industry are deferred for special skill, yet industry as a whole has been forced to accept what the military establishment has rejected from their point of view as unsuitable. More than 5,000,000 men have been discarded as fighters and these men were left for industry and other occupations to absorb. In addition, at present, pre-employment examinations are at a very low ebb. Hours are long and the work week consists often of six or even seven days. Women are employed as substitutes as the healthy males are inducted. War working conditions are poor and below peacetime standards.

Despite all the handicaps faced by management and labor, production has proceeded at a very high level. It has been estimated that since July 1940 the war production plants, including clothing manufactured for the armed forces, have turned out war material valued at more than \$170,000,000,000 (August 1943 price level). While this tremendous output was being accomplished, livestock production steadily increased. In 1944 this production expanded from 29,659,000,000 pounds to 41,755,000,000 pounds, or an increase of 41 per cent over the average for the years 1935-1939. Total agricultural production in 1944 was increased by 33 per cent over the average for the period 1935-1939.²

MEDICAL ATTENTION TO HYGIENE AND HEALTH
OF WAR WORKERS

The problem of hygiene and health were early recognized. They were met through the cooperation of medicine, public health, management and labor, and the government—especially through the help of local health authorities. In most instances each problem presented received prompt and effective attention. Considering the magnitude of the problems involved, the results have been eminently satisfactory. Medical cooperation has been a real factor in our splendid record of production achievement.

FOOD PRODUCTION: THE FARMERS, THEIR DEFERMENT AND THEIR HEALTH

The health of the farmer is a national problem. Food production also is obviously essential to the welfare of the nation. Hence farmers, as essential workers, received special consideration in deferments under the Selective Service System. In this country there are at the present time 6,000,000 farms and 12,000,000 farm-

ers considered as family and hired workers. As of Sept. 1, 1943, 1,600,000 farmers 18 to 37 years of age were being deferred and an additional 550,000 farmers were liable for military service but were not being called at that time because of their age, 38 to 45 years. Now in 1945 the situation is essentially unchanged. Deferments for farmers 18-37 years of age are still running in the neighborhood of 1,600,000.

Since 1939-1940 some 4,500,000 men have left the farms and approximately 1,200,000 have been inducted. Most of the others have found their way into cities and towns and have entered some form of industry. As a result, farm labor is scarce. Despite manpower shortage, our food production is high; in fact, the highest in our entire history. Food production has been sufficient to meet the needs of fighting men and our people at home, with enough left over to supplement materially the food supply of our allies. Food restrictions have not been sufficient to date to affect in any way the health of our people. In fact, nutrition is probably better now than in peacetime because of better wages and the greater purchasing power among the poor.

RURAL HEALTH AND MEDICAL CARE

Surveys of the health situation among the rural families in some of the states indicate that a large proportion of farmers have poor health, that the facilities for health services are below normal requirements and that there is a pitiful inadequacy of the care provided regularly for the lower income families. A look at some of the surveys indicates that between one third and one half of the lower income groups have no medical or dental care whatsoever. Of the 16,000 cases of serious illness reported by farm families in Texas and Oklahoma, less than one half had a doctor's care. Only one out of three births was attended by a physician.³

Physical examinations of farmers in three Nebraska counties revealed that about 72 per cent of men would not have met the current standards for military service. In rural areas, death rates among mothers and infants far exceed those of urban mothers and babies. At almost every age level, death rates are greater in rural areas, and especially in towns and cities from 2,500 to 10,000 population, than in our largest urban centers.⁴ In recent examinations, farm youth 18 and 19 years old showed the highest Selective Service rejection rate for physical, mental or educational defects of any occupational group: 41 per cent compared to an average of 25 per cent for other groups.⁵

In most rural counties, public health services and hospitals are far from adequate. For years physicians have been leaving not only the rural areas for the cities, but the poorer agricultural states for more prosperous ones. Before the war, many areas had but one physician for every two or three thousand people. War has further aggravated this situation. More rural physicians have entered the armed forces than have urban ones. Most of those remaining are older men. If rural areas are to have more adequate health service to meet the needs of the future, comprehensive plans must be made for this service.

The national physician-to-population ratio which is considered the minimum necessary to protect civilian health is probably about 1 to 1,000. Individual areas

⁴ Anderson, Elm L.: Adequate Medical Care for Rural Families, J. Home Econ. 36: 397 (Sept.) 1944.

⁵ Fact Sheet on Rural Health and Sanitation, United States Department of Agriculture, Jan. 3, 1945.

² Information supplied by the Division of Economic Information, Bureau of Agricultural Economics, U. S. Department of Agriculture.

are considered critical if they have a ratio of one physician to 1,500. In April 1942, sixteen rural states had less than one active private practitioner for 1,500 people in 1,005 rural counties which neither included a metropolitan center nor were adjacent to counties which had metropolitan centers. The total population of these counties exceeded 22,000,000. The average number of persons per active practitioner in these 1,005 counties was 2,015. In the same month an equitable distribution of the nation's available physicians could have provided one for every 937 persons.

The shortage of dentists in rural areas is even worse. One Southern state reported one dentist to every 11,000 people for the entire state. The teeth of many farmers and members of their families are in need of dental work. Among hundreds of thousands of farmers, dental care is practically unknown. And it is not only their teeth that suffer, but sometimes their entire system as a result of neglect of the teeth.

Many rural areas have inadequate or no hospital facilities. It has been estimated that over 1,200 counties of the United States are without a single satisfactory general hospital. While some of the counties have had some service from adjoining counties, many are in dire need of hospitals—at least emergency facilities.

In 1941, of America's 3,070 counties, 1,400 were without services of full time departments of public health—and practically all of them were rural counties. The situation now is even worse because of the war.⁶

If rural people are to share more fully in the benefits of modern medical science, they need immediate help in four areas: determining need for physicians and means of attracting them to rural areas after the war, getting legislation to enable communities to establish hospitals and health centers, setting up programs that emphasize preventive medicine rather than catastrophic illness and carrying out an educational program that will clarify the issues involved.

THE GENERAL WARTIME PICTURE OF THE HEALTH OF THE NATION

Despite the stress and strain of worldwide conflict, the health of the people remains good, surprisingly good in the extraordinary situation. The mortality statistics for 1943 and 1944 reveal a death rate unprecedentedly low. In the first month of 1945 the general death rate, estimated from the 10 per cent mortality sample, was 11.3 deaths per thousand of population, which is significantly lower than the rate of 13.4 for January 1944 and 6 per cent lower than the expected rate. Fortunately, the nation has been spared any serious epidemic.

But despite the low mortality figures, war has taken a definite toll of the health of the civilians. Families and homes have been disrupted. Emotional and mental distresses increased greatly. Men and women were breaking physically, emotionally and mentally in large numbers. So in addition to the great demands on war medicine some serious health problems are being encountered on the civilian front especially in the field of nervous and emotional disorders. Medical men, wherever they may be, are heroically attempting to meet the old and new challenges with new ideas, new principles and new methods of practice.

BROAD CONSIDERATIONS BEARING ON INDUSTRIAL MEDICINE

Jobs for 60,000,000 workers is the postwar employment objective. In this country and in most civilized nations, labor is struggling with fundamental social

problems having to do with the welfare of the people. The International Labor Code of 1939 reveals the depth and breadth of these efforts. Many of the questions with which labor deals present medical angles. Only through wise medical guidance can best solutions be obtained. Obviously employment itself, a living wage, a satisfactory home and proper nutrition are all essentials here as everywhere. Wages, working hours, rest periods and an annual holiday are of national concern to all. The employment of minors, their training and pay, and especially their use on night shifts needs careful supervision. The employment of women, now so general, calls for special consideration. Problems of industrial health, safety and welfare are newly laid at our door. Social insurance is struggling for recognition. New legislation is being sought. Labor statistics are being compiled. Migration is receiving consideration. Standards for judgment and action are being devised. These represent broad considerations in which medicine must take its stand.

Employment is essential to life, liberty and the pursuit of happiness and also to mental, moral and physical health. Employment will have to be found not only for those now at work in this country but for the 10,000,000 men and women who will return at the close of the war. Adjustment to peacetime employment will in most instances be just as difficult as that required on entering military service. Hence proper provision must be planned and made available in advance of the return of the veterans. With 60,000,000 people to be employed in the plants and shops and on the farms this represents the greatest postwar problem which the nation and the healing arts have to face.

THE MEDICAL PROFESSION AND EMPLOYMENT OF WAR VETERANS AND OF THE HANDICAPPED

While this nation was at war medicine and dentistry were likewise at war. No part of the entire war effort—combat, production or agriculture—was more effective than was that of the professions of medicine and dentistry. Industry faces the greatest problem of its history in the forthcoming postwar period. Labor, management, medicine and dentistry must unite in a common effort in which the rights of all must be considered. The welfare of each group must be considered in the great cooperative efforts necessary to meet the great problems. The high ideals of the medical and dental profession will meet the new situation in terms of its.

In the postwar period many changes will be effected. More and more professional men will enter into industrial endeavors. Industrial medicine will demand the maximum efforts of the medical and dental professions. Medicine stands ready in this emergency, as in all others, present and past, to do its share. This, however, should be done through cooperation and not by coercion. Only plans winning whole-hearted medical support will yield maximum results.

THE HANDICAPPED AND THEIR EMPLOYMENT

The war has centered attention on the employment of the handicapped. This will be an important problem in postwar industry. Manpower shortage already has compelled the employment of great numbers of the halt, the lame and the blind. Management has been able to find some place for all handicapped workers to make a contribution to the war effort. Management states that the major difficulties rest not with the individuals concerned but with problems of insurance and

6. Fact Sheet on Rural Health and Sanitation, pp. 2-4.

unionism. Medicine believes that there is a definite place in industry for handicapped persons, including the cardiac provided proper consideration is given to their examination, placement and routine check-up.

Absorbing the disabled veteran so that he may take his place in society is one of the major tasks of business and industry. Although the first responsibility for rehabilitation and vocational adjustment of discharged servicemen in the United States is placed on the Veterans Administration, much of the responsibility for the veteran's return to normal life falls upon industry. It is not a responsibility that will be shirked. Individual companies throughout the country are making plans not only to take back into their organization those of their own employees who have become disabled but to absorb as many as possible of the handicapped servicemen who have not previously been employed by the company. Many successful programs are already in operation.

The medical profession has much responsibility in helping disabled veterans make their adjustment. The doctors and dentists who are associated with industrial and business firms, either on a full or on a part time basis, will have an especial opportunity in this regard.

The successful placement of handicapped workers requires close coordination of efforts of the personnel and medical departments. Mr. Michael Supa, supervisor of the physically handicapped personnel of the International Business Machines Corporation, who is himself blind, writes:

Proper placement of the physically handicapped person has the same results as the proper placement of nonhandicapped individuals. If properly placed, the physically handicapped person is not a handicapped worker.

War casualties are now bringing into industry in large numbers persons with physical defects of all kinds, loss of arms and legs, of vision and of hearing. Fortunately the Medical Corps of the Army and Navy have gone to great lengths to train these victims of violence with physical and mental handicaps and condition them for future employment. The majority of such men will face their problem of peacetime employment with the same kind of courage, ingenuity and understanding that characterized their actions on the field of battle. As long as these victims are willing to work and to approach employment in a cooperative spirit, all these major problems should be susceptible of solution, including matters pertaining to insurance and to unions. Success will depend largely on the spirit of veterans, of labor and of management. But since the rights of veterans have been bought on the field of battle and have been paid for in advance, the American people, if need be, will see that these rights are recognized and met.

MEDICAL EDUCATION AND RESEARCH

Many of the medical and dental officers who have served with the Army and Navy will seek refresher or postgraduate courses before they return to civilian practice, while others will want to undertake such training after they resume civilian practice. Expansion of special training facilities through increased provision of teaching hospitals and medical centers will be required.

Tremendous progress has been made in medical research during the war. The curative powers of penicillin and sulfonamide drugs, the life saving value of blood plasma and serum albumin and typhus vaccine, and the development of new malaria control methods

are all fruits of a concentration and expansion of medical research resulting from determination to win the war. Adequate financing, coordination and teamwork have been the keys to this success. Through governmental agencies, such as the Army, Navy and the Office of Scientific Research and Development, and quasigovernmental agencies such as the National Research Council, and nongovernmental agencies such as the universities, pharmaceutical houses and other groups, the nation's resources for research have been mobilized in a vast cooperative effort.

With victory attained, we now approach the challenges of peace. Many problems await solution. Much long-term, as well as short-term, research into the cause and cures of cancer, arteriosclerosis, hypertension, dental decay and nervous and mental disorders must be undertaken in order to assure further progress against disease.

THE NEED FOR ORGANIZED RESEARCH FOR INDUSTRIAL HEALTH

The professions of medicine and dentistry and the medical and dental schools must organize research in the interest of industrial health and hygiene, for the purpose both of making new discoveries and adding new techniques and of utilizing more effectively the wide but unrelated knowledge and technic that already exists. Research as an important basic instrument in our program must not be overlooked and for the long run it is absolutely essential. It means that all workers will work more effectively and will bring about greater advances. To complete the whole program, professional training of old and new workers in the industrial field will need to be added to organized research. Let us look briefly at a practical program already proposed.

THE NEED FOR A BASIC TRAINING PROGRAM FOR INDUSTRIAL HEALTH PERSONNEL

Nor must one forget that the whole program for the improvement of industrial health will require a definite educational program. This will have to take the place of our very incomplete and fragmentary efforts at the present time in providing systematic facilities for instruction in modern health industrial methods both before and after graduation. Such instruction will have to be a part of the curriculum of the school for the undergraduate. Provision will have to be made also for advanced systematic study in bona fide graduate instruction as well as continuing postgraduate instruction for the doctor engaged in practice. In a report by committees representing the American Association of Industrial Physicians and Surgeons and the Council on Industrial Health of the American Medical Association, the need for a unified plan is expressed "which assigns overall responsibility for coordinated classroom discussion, field studies and laboratory and section work to one single teaching division, preferably preventive medicine and public health. There must always be considerable dependence on clinical teaching in the medical and surgical aspects of industrial practice, but the testimony of recent graduates clearly indicates that older methods of divided and unrelated instruction fail to provide dependable and reasonably complete information." The same committee emphasizes the need to teach the administrative aspects of industrial health organization in plants, factories, mines and stores. It outlines two additional aspects of the content of instruction to be given as (1) industrial hygiene and toxicology

and (2) industrial medicine and traumatic surgery. In the former, emphasis will be placed on prevention as a cardinal principle for reducing the incidence of disability in industry. In the second phase the object will be the "full restoration of the injured worker to his former earning capacity in the same line of work and without unnecessary delay." The whole program will promote industrial efficiency, increase earning power and establish cooperative, industrial relations. All of these will contribute to the most effective organization of the labor force and make available manpower serve more effectively the public interest and promote the common welfare.

CONCLUSION

The postwar situation is a challenge which American medicine cannot and will not ignore. As medical advisers of the greatest of industrial nations, American medicine will serve to keep American leadership and supremacy. It will be found cooperating with labor and with management and will be giving the individual workman and farmer a medical care better than elsewhere available in the whole world. It will, by its research, its ingenuity, its professional knowledge, help create the standards for employment conditions which, together with an individual care comparable to the care it gave the American soldier, will make American manpower, in quality and quantity of production, the greatest in the world.

CLINICAL AND EPIDEMIOLOGIC ASPECTS OF EPIDEMIC PLEURODYNIA

SAMUEL J. NICHAMIN, M.D.
Surgeon (R), U. S. Public Health Service
MEMPHIS, TENN.

In recent years the medical profession has become alerted to a disease, pleurodynia, which was relatively unknown twenty-five years ago. Its frequent dramatic appearance in epidemic outbreaks over widely separated areas of the world has elicited many and varied clinical descriptions. The American reports of epidemics together with historical summary of the disease have been enumerated in a recent paper by Tasker Howard¹ and his associates describing an epidemic in Brooklyn in 1942.

The great majority of the authors have stressed the extent of the epidemic, its distinctive clinical characteristics, the essentially benign character of the disease, its self-limited course free from sequelae, and its importance in diagnostic differentiation from many more serious medical and surgical conditions. In addition to the epidemic of 75 cases reported here, I have encountered many additional sporadic cases in various other communities. As knowledge and awareness of the disease picture become more widely disseminated, a more precise estimate of its true incidence in both its sporadic and its epidemic form may be realized.

Less consideration has been hitherto directed toward the morbidity aspects of the disease. The afflicted individual, although reassured as to his ultimate recovery, nevertheless finds himself relatively incapacitated and unable to perform his regular duties successfully over an indefinite period of time. Such disability when multiplied *en masse* for an entire group of a working population may exert a significant effect on industrial efficiency. One of my purposes in this paper is to focus attention on the subjective reactions of the ailing indi-

vidual. More accurate appreciation of these factors may alter our concept of the disease and reorientate our ideas of the degree of incapacity associated with it, while noting its effect on economic loss.

A clearer delineation of the disease syndrome and its economic implications would be an effective stimulant toward expanding our knowledge of the epidemiologic aspects of the disease. Only scant reference has been made in past reports of epidemics of epidemic pleurodynia to its mode of spread and communicability. Adequate information concerning these factors has been far from satisfactory. For the public health control of the disease, it is essential that more epidemiologic data be forthcoming.

In the early summer of 1944 I was confronted with an outbreak of epidemic pleurodynia on an island war housing project for shipyard workers. In view of the uniformity of environmental conditions and the economic status of the population, a study of the disease, with emphasis on its clinical behavior, morbidity and epidemiologic characteristics, seemed opportune. The circumstances were such as to preclude an accurate statistical study of the daily clinical progress of the individual patient, the number of relapses, the exact duration of the disease or the amount of absenteeism from work. Because of limited laboratory facilities, studies on the etiology or pathogenesis of the disease were not pursued. In the past, attempts at determining the etiology of the condition have completely failed. Intensive laboratory and bacteriologic studies such as those carried out by McDonald, Hewell and Cooper² have yielded negative results. However, recent work at the National Institute of Health has given promising results toward establishing a virus as the infectious agent.

During a period extending from the last week of June 1944 through the middle of November 1944, 75 cases of epidemic pleurodynia or myalgia were collected on Blakely Island, a war housing project, located on an island in the Mobile River, which lies adjacent to a large shipbuilding yard. Occupancy of the 1,200 apartments in this project was limited to employees of this concern. A tunnel for automobile traffic connects the island with the mainland. This group of shipyard workers and their families consisted of white persons, most of whom came from rural areas of Alabama and Mississippi.

EPIDEMIOLOGIC DATA

At the outset it was decided to study the manner of spread of the epidemic by locating each case as it occurred on a spot map of the island housing project. By following the chronological incidence of cases in families, and their successive occurrence in localized areas, it was hoped to secure information bearing on the degree of infectivity of the disease, its relation to environmental factors and the duration of the incubation period. Estimation of the latter has thus far been rather indefinite.

Three weeks after the appearance of the first case, a total of 19 cases had been accumulated. Of these, 6 cases (32 per cent) were confined to an area of three blocks (area I, fig. 1). Seven cases (37 per cent) were in a corresponding area (area II, fig. 1) to the left of the center block of the housing project. The remaining 3 cases were distributed to each of three sparsely populated border zones (areas III, V and VI, fig. 1). With increased incidence of the disease, the bulk of

108 A 3d, 106 A 3d and 104 D 3d, with intervals of approximately twenty-two days and forty-eight days respectively. Pairs of cases taken at random throughout the island, as A5, A11, reveal a ten day interval; o1 and S2, a twenty day interval; s3 and S5 (adjoining apartments), a nine day interval; Jn7 and j4 (adjoining apartments), a six day interval.

In each of 2 instances, a6 (208 A West Avenue) and all (204 D West Avenue), the symptoms of epidemic pleurodynia occurred in persons who had been living on the island only over a two week period. j3 and j12 represent cases in a son and his mother occurring on July 5 and July 15 respectively, an interval of ten days. In most of the cases the dates mentioned represent the first visit made instead of the date of onset of symptoms. This would therefore tend to alter the accuracy of any estimated incubation period.

Reference to figure 2 reveals two fairly abrupt rises in the case frequency curves of area I, the first occurring at the end of the first week in July and the second in the third week of August. On the other hand, the curve of area II shows a more even and gradual curve up to the beginning of September, after which no further cases occurred until the third week in October. Four cases then developed in a period of ten days. With the onset of cooler weather no further cases were observed.

It is to be noted that, for the most part, the aforementioned data are necessarily circumstantial and presumptive. Nevertheless, one may venture an approximate estimate of the incubation period as between one and three weeks.

The epidemiologic evidence of spread of the disease by intimate contact seems substantiated by the fairly characteristic distribution of cases in adjoining apart-

ments and within the same household. Yet in many instances only 1 member of a household would develop the disease. The degree of infectivity was therefore rather variable and often not particularly high. Individual susceptibility or immunity are factors that need further investigation in relation to the infectious agent. The concentration of cases in the more congested areas of the community would tend to implicate overcrowding as a factor in the spread of the disease by contact. Most of the apartments were rather small, averaging four or five less than medium sized rooms; yet often they contained several families or several boarders. No other significant environmental factors could be ascertained in relation to the mode of spread of the epidemic or to the sudden rises in the curve of case frequency of area I. One might add that an excessive amount of rainfall with periods of continuously high humidity had been present during the spring and summer of 1944 in Mobile. Harder,³ in describing an epidemic of pleurodynia in southwestern Ohio, commented on the occurrence of warm moist weather and stated that the amount of rainfall had been more than usual. The majority of our cases occurred during the warmest months of the year as prevailing in the deep South (table 5). The highest number appeared in July and August, namely 21 and 22 cases respectively.

In conformity with previous reports, this outbreak of the disease was most prevalent among persons under 30 years of age, totaling in this category 51 cases

3 Harder, F. K. Epidemic Myalgia or Pleurodynia in Southwestern Ohio, *Am J M Sc* 1911: 678-685 (May) 1936

(68 per cent, table 2). There were only 6 children 10 years of age and under. The youngest patient was aged 7 and the oldest 69.

The sexes have usually been equally affected by this ailment. However, in this group there was a preponderance of females. As noted in table 3, there were 27 males (36 per cent) as compared to 48 females (64 per cent). The significance of this fact on age and sex distribution is limited because of the distinctive nature of the industrial population on the island.

CLINICAL MANIFESTATIONS

Only 10 of the 75 cases (table 4) lacked a history of an abrupt onset, a characteristic finding of the disease. The majority of patients would spontaneously mention the exact hour at which the symptoms first became apparent.

Prodromal symptoms associated with upper respiratory infections were noted in only a small number of cases. Thus, sore throat or a burning type of dis-

comfort in the pharynx were complained of by 9 patients. This finding is in contrast to other epidemics, in which pharyngitis has been a rather prevalent symptom. In 9 cases chills were mentioned as preceding the onset of the illness. Patients frequently related a history of a preceding "run-down" condition that had existed over a variable period of time.

A febrile reaction has been one of the most constant findings associated with cases of epidemic pleurodynia. MacDonald⁴ reported an incidence of 91 per cent in 70 cases. Table 6 reveals that more than half of the patients in the present series were practically afebrile. Often a patient would complain of feeling flushed or feverish despite the presence of a normal temperature. In about one third of the cases a low grade fever up to 101 F. was present. In a smaller group of 10 cases (13 per cent) the temperature was over 101 F. and in 1 case reached as high as 105 F. Except for an occasional case with bradycardia, no significant alterations of the pulse were noted.

Because of the diverse symptomatology of the disease and the ease with which it could be confused with many

other serious medical or surgical conditions, those cases that did not present pain and tenderness in the epigastrium or in either of the subcostal regions were absolved from the diagnosis of pleurodynia. The pain was most frequently of a paroxysmal, lancinating type and radiated throughout the trunk in all directions. Burning or knifelike were terms often used to describe the pain.

			Over 100	9	16

Others stated that it "cut their breath off" and in many instances a "smothering" sensation was complained of substernally. There was a conspicuous absence of complaints involving pain or aching of the extremities. Variations of the severity of the pain or discomfort seemed directly related to the individual's inherent pain threshold. Moderate palpation over the tender muscles in the epigastric region often elicited severe, inwardly radiating pain associated with a transitory feeling of nausea. In certain individuals objective findings of tenderness in muscles of the upper abdomen were discovered on physical examination, in the absence of subjective complaints.

Table 7 shows the site and frequency with which various areas were involved. It is noteworthy that the trapezius muscles were affected in 29 cases (39 per cent). Scant reference has been made in the literature to such involvement. However, Ronald⁵ has noted that, in addition to the abdominal muscles, there is particular involvement of the muscles around the shoulder girdle and neck in some cases of epidemic pleurodynia. On the basis of anatomic and physiologic facts relating to the innervation of the diaphragm by the phrenic and intercostal nerves, he concludes that the clinical manifestations of the disease are due to a pathologic disturbance of the diaphragm or its overlying pleura. Backache was complained of in 22 of our cases (29 per cent). This was referred most frequently to either of the costovertebral areas. A number of patients disclosed the fact that their abdominal or thoracic pain

became aggravated with movements of the body, deep breathing or coughing.

The presence in 31 cases, or 41 per cent, of acute pain and tenderness in the lower right abdominal region overlying the appendix is an indication of the importance of considering pleurodynia in the differential diagnosis of acute appendicitis. Awareness of the essential clinical features of pleurodynia would lead to more accurate diagnoses of such acute surgical emergencies. One should never relax one's vigilance regarding the possi-

4. MacDonald, R. R.: Epidemic Myalgia or Pleurodynia. *Pennsylvania M. J.* 41:519-520 (July) 1938.

5. Ronald, James: *Bornholm Disease*. *J. Roy. Nav. M. Serv.* 28: 144-149 (April) 1942.

bility of acute appendicitis when confronted with any type of acute abdominal pain. Nevertheless, major surgery is not indicated in the treatment of a benign condition such as pleurodynia. Other acute intra-abdominal conditions that need to be differentiated from pleurodynia are acute cholecystitis, perforated peptic ulcer, gastroenteritis and pelvic inflammations. Among other conditions might be mentioned coronary disease, pleurisy, influenza, pneumonia, rheumatism and diseases of the genitourinary system.

The subjective systemic reactions displayed by patients suffering from pleurodynia are in many respects as important in the clinical picture of the disease as are the aforementioned objective findings. In many instances they may even overshadow the latter. In general the patients appeared languid or lethargic, exhibiting varying degrees of prostration and malaise. The peculiar, distinctive character of the pain or discomfort seemed so totally unfamiliar to them that they appeared baffled and often apprehensive as to the pos-

sensations were described usually in the upper extremities. Certain individuals reported fainting attacks. Some were aware of an aching, burning discomfort in the eyes. Another complaint was that of difficulty in focusing their eyes on near objects.

Laboratory findings were necessarily incomplete. At best, such data offer no particular aid in diagnosis or prognosis. A noticeable feature in table 9 is the relatively low levels of hemoglobin and red blood cell counts. The white cell blood cell count was 8,000 or below in 13 out of a total of 16 such counts. The differential counts appeared to be within normal limits. Three fourths of the sedimentation rates performed proved to be elevated. Such preponderance of high sedimentation rates is in agreement with a similar proportion of high sedimentation rates culled from table 1 of the paper by Howard and his associates.¹ Further investigation of this finding in relation to epidemic pleurodynia would seem to be indicated.

Although the duration and course of the disease are unpredictable, one can remain quite confident of its benign termination. The average duration of the present group of cases appeared to be one to two weeks and sometimes longer. A few persons reported residual areas of tenderness in the lower thoracic and upper abdominal regions as long as six to eight weeks after the acute symptoms had subsided. Prognostically one can unreservedly reassure the patient as to his eventual recovery without complications. Only one of my patients, a child of 8 years, developed otitis media during the course of the disease.

sibility of heart trouble or other serious ailments. Weakness and fatigability aggravated their feeling of wretchedness. Attempts at remaining ambulatory or continuing at their work usually provoked increasing nervousness, irritability and exhaustion until the patient finally succumbed to bed rest.

One of the foremost complaints was that of frontal headache, noted in 43 cases, or 57 per cent (table 8). It was of a constant, dull character in contrast to the sharp, intermittent pains referred to the region of the occiput. Dizziness, usually associated with the headache, was present in 30 cases (40 per cent). In most reports digestive disturbances have been noted in one third or less of the cases. However, in our series nausea appeared more prominently, involving 61 per cent of the cases, and vomiting was noted in 40 per cent. The incidence of diarrhea or constipation was indeterminate, since self medication during the initial stage of the illness seemed an almost universal practice.

An interesting feature of this outbreak seldom mentioned in previous reports was the presence of paresthesias, especially in females, which occurred in 21 cases (28 per cent). Numbness, tingling and pricking

COMMENT

In the absence of a known etiologic agent, only symptomatic therapy can be applied for relief from the noxious effects of the disease. Efforts were made to provide effective therapeutic agents so as to enable the patients to resume their important wartime duties within the shortest time, thereby preventing relatively long periods of absenteeism. No such hopes were realized, except for temporary relief secured by the local application of heat and occasional strapping of the lower thoracic region. In spite of the multiplicity of therapeutic agents exhibited, including the sulfonamides, vitamin B₁ and neostigmine, no convincing beneficial results materialized. Certain patients did seem to respond to one or the other of these agents, but the results did not appear to be consistent beyond a certain proportion of cases. Definitive therapy for this disease will depend on the isolation of a specific etiologic agent. In the Annual Report⁶ of the U. S. Public Health Service there is a statement relating to the fact that the blood, spinal fluid and nasal washings of human cases of epidemic pleurodynia have yielded an agent pathogenic for monkeys. Further development of such virus studies are in progress (personal communication).

Many reports have stressed the high incidence of involvement of children as well as young adults. Only 6 children under 10 years of age (8 per cent) were noted in our series. In them, the salient presenting features were the abdominal complaints. The ever present shadow of possible acute appendicitis was a matter of great concern to the parents. An accurate evaluation of the clinical picture as a whole, and the presence of acutely painful and tender muscles elsewhere over the abdomen as well as around the thorax, the neck, and high in the epigastrium, may aid in the differential diagnosis.

6 Annual Report of the United States Public Health Service for the Fiscal Year 1944, Federal Security Agency, Washington, D. C.

It is my conviction that sporadic or epidemic cases of pleurodynia are more prevalent than would be inferred from a perusal of the literature in this field during the past two decades. Certain obscure conditions relating to virus infections and simulating acute surgical conditions of the abdomen have been reported. Butsch and Harberson⁷ recently reported a series of 50 cases of an acute virus infection with nerve root involvement simulating appendicitis. Of this group 13 were operated on and normal appendixes were removed. Further study revealed a definite syndrome characterized by an abrupt onset of abdominal pain, nausea and vomiting. Aggravation of the pain by coughing or deep inspiration was noted. The authors' diagrams reveal the areas where the abdominal pain and tenderness were found; namely, on the right side at the level of the umbilicus, next in the right subcostal border and right lower quadrant, and lastly in the epigastrium and left subcostal regions. These cases occurred during the summer and fall months. Laboratory findings were not significant. A punctate erythematous edema of the palate was noted in most of their patients. It is conceivable that closely related viral agents might be responsible for the striking similarity in the clinical manifestations between this syndrome and that of epidemic pleurodynia.

SUMMARY

A survey of the clinical and epidemiologic aspects of an outbreak of 75 cases of epidemic pleurodynia reveals that its role as a communicable, incapacitating disease, contributing to economic loss through absenteeism and simulating more serious medical and surgical conditions, should not be underestimated.

The Rise of American Gynecology.—From a practical point of view, gynecology of the nineteenth century was essentially American. The superb contributions of Ephraim McDowell (1771-1830), James Marion Sims (1813-1883), the Atlee brothers and Thomas Addis Emmet (1828-1919) solved several of the major therapeutic problems of this specialty. To these we may add the names of other surgeons who ventured to invade the pelvis during the preantiseptic days: Nathan Smith (1762-1829) of Yale, John Lambert of Richmond, François Prevost (1764-1842) of Louisiana, William Gibson of Baltimore, Alban G. Smith of Kentucky, Gilman Kimball (1804-1892) of Massachusetts, David L. Rogers of New York, J. C. Warren of Boston, J. Bellinger (1804-1860), A. Dunlap (1815-1894), Nathan Bozeman (1825-1905), E. R. Peaslee (1814-1878) and D. Hayes Agnew (1818-1892). Daring indeed were John King and his fellow townsmen T. Gaillard Thomas and A. J. C. Skene (1837-1900) for their deliberate performance of a laparo-elytrotomy. George Osgood reported a laparotomy for extrauterine pregnancy in 1802, and in the following year David Ramsay (1749-1815) of Charleston reported a similar operation. In 1816 John King of Edisto Island, South Carolina, performed a remarkable operation for abdominal pregnancy, saving both mother and child by cutting through the walls of the vagina and applying forceps, with abdominal pressure exerted on the fetus. He afterward expanded his account of the operation with his observations into a volume of one hundred and seventy-six pages and published it at Norwich, England, in 1818. Joseph Pancoast (1805-1882) of New Jersey was the first to perform a successful plastic operation for extrophy of the bladder. This operation was repeated with success on the female bladder by Daniel Ayres of Brooklyn (1822-1892) in November 1858.—Ricci, James V.: *One Hundred Years of Gynaecology*, Philadelphia, Blakiston Company, 1945.

IS SURGERY INDICATED IN ALL CASES OF NODULAR GOITER, TOXIC AND NONTOXIC?

J. WILLIAM HINTON, M.D.

AND

JERE W. LORD JR., M.D.

NEW YORK

From an analysis of the data presented in this paper we believe the following two theses to be true:

1. All nontoxic nodular goiters—single and multiple—should be removed surgically because of the high incidence of unsuspected cancer, a rate which exceeds that of cancer of the breast in the clinically benign appearing group.

2. Toxic nodular goiters should be removed surgically and should not be treated with thiouracil.

Two recent papers¹ have emphasized the high incidence of malignant degeneration in nodular goiters. Ward¹ presented an incidence of 4.8 per cent in 3,539 nodular goiters of both sexes. In males the incidence was 11 per cent and in females 4.0 per cent. Cole and his associates¹ showed the incidence of carcinoma in 523 nodular goiters (including toxic, nontoxic, benign and malignant) to be 7.2 per cent. However, a breakdown of their cases revealed the following extraordinary facts: In 193 cases of nontoxic nodular goiter there was an incidence of 17.1 per cent of carcinomas, while in the group of nontoxic solitary nodules 24 per cent were the seat of carcinoma.

We reviewed the cases of nodular goiter in which we operated during the past five years and after eliminating all the cases in which the diagnosis of carcinoma was made preoperatively and confirmed pathologically we were left with 184 cases of clinically benign nodular goiters (some were toxic and some nontoxic) which showed an incidence of 7.6 per cent of cancer on pathologic examination. This figure is in close agreement with that of Cole and his associates.

We believe that an incidence of 7.6 per cent of cancer in cases of apparently benign nodular goiters is a compelling reason for operative removal of all such nodules unless a strong contraindication exists. To reinforce this thesis we have made the following study on breast tumors. It is generally agreed among internists and surgeons that biopsies should always be taken of a "lump" in the breast, followed by a radical mastectomy if proved malignant. This policy holds, regardless of how innocent clinically the "lump" may seem.

At the New York Hospital the following data were accumulated: Two hundred consecutive pathologic specimens of breast lesions were studied, and it was observed that 140 (70 per cent) of them were benign, and 60 (30 per cent) were malignant. The charts of 30 consecutive malignant cases then were reviewed and it was evident from the clinical data that only 5 out of 30 cases were considered benign. The remaining 25 cases clinically exhibited the characteristics of cancer. Therefore out of every 75 lesions clinically benign only 5 are proved to be malignant on biopsy by the pathologist—an incidence of 6.7 per cent. Yet no one would criticize the policy of routine biopsy of a "lump" or mass in the breast, as reference to the accompanying

1. Ward, R.: Malignant Goiter, *Surgery* **16**: 783-803 (Nov.) 1944. Cole, W. H.; Slaughter, D. P., and Rosciter, L. J.: Potential Dangers of Nontoxic Nodular Goiter, *J. A. M. A.* **127**: 883-888 (April 7) 1945.

table will show. Hence we feel that the same attitude and policy is justified when one is dealing with a nodular goiter whether solitary or multiple, nontoxic or toxic. The operation on the thyroid gland performed by a surgeon experienced in thyroid surgery is not dangerous, entails only three to four days' hospitalization and in the nontoxic group should be without mortality. The technic of thyroidectomy and our experience with the nontoxic nodular goiters will be published elsewhere.

The second thesis, i. e. thiouracil should not be used in cases of toxic nodular goiter, is based on the practical grounds outlined in the first thesis and on the theoretical grounds to be discussed.

Broders and Parkhill² stated recently that "microscopically the thyroid gland in cases of Graves' disease treated with thiouracil shows extreme hyperplasia with heightened epithelium, marked papillary infolding, and mitosis in the epithelial cells." And again the same authors state that "the thiouracil goiter is more of a cellular hyperplasia with mitosis very much in evidence, and so therefore more comparable to a carcinoma of the thyroid." Bielschowsky³ has reported the unusual finding that the carcinogenic agent 2-acetylaminofluorene which produces a wide variety of cancers in the rat fails to produce any such change in the thyroid gland unless thiourea is administered simultaneously. In that

Incidence of Clinically Unsuspected Cancer in Breast and Thyroid Nodules

	Number of Cases	Number of Cancers	Per Cent
Breast.....	75	5	6.7
Thyroid.....	181	11	7.6

case adenomatous or anaplastic invasive epithelial tumors of the thyroid gland may develop.

In a recent editorial in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION⁴ attention was drawn to these experimental findings of Bielschowsky and the possible significance of the use of thiouracil in man for the treatment of hyperthyroidism. Ward¹ has stated that carcinoma occurred in only 1 instance in his series of 1,900 toxic diffuse goiters; hence the potential danger of thiouracil in this group of hyperthyroid patients is slight. On the other hand, because of the facts presented in thesis 1, i. e. 7.6 per cent of clinically benign nodular goiters are malignant, and because of the observations of Broders and Parkhill and of Bielschowsky, we feel that thiouracil is contraindicated in the treatment of toxic nodular goiter and that operative intervention should be employed.

CONCLUSIONS

1. All nontoxic nodular goiters should be removed surgically because of the relatively high incidence of unsuspected cancer.

2. Thiouracil is contraindicated in the treatment of toxic nodular goiter and operative intervention is the treatment of choice.

IMMEDIATE CARE OF THE WOUNDED THORAX

MAJOR PAUL C. SAMSON

MAJOR BENJAMIN BURBANK

MAJOR LYMAN A. BREWER 3d

AND

MAJOR THOMAS H. BURFORD

MEDICAL CORPS, ARMY OF THE UNITED STATES

The experience which has been gained in the early preoperative care of severe thoracic battle casualties can, in large measure, be applied to the primary management of thoracic injuries in civil life as well. As far as this is true the following presentation may help to place such therapy on a firmly established basis in civil practice. The discussion is based on work in the Mediterranean and European theaters over a period of two and one-half years by us and our colleagues of an auxiliary surgical group.

First aid treatment of the thoracic casualty is initiated on the battlefield by company aid men. These soldiers are taught that sucking wounds should be closed with a dressing large enough to stop the sucking noise, that a "stove-in" chest should be bandaged snugly, that the wounded man should be urged to cough if he has a rattle in his windpipe and that he should be transported in a sitting position if he has difficulty in breathing when lying down. Further treatment is given at the battalion aid station under the supervision of a medical officer. Here, dressings are adjusted when necessary and petrolatum gauze is packed in a sucking wound; morphine may be administered and plasma given. The patient receives a high priority for evacuation to a clearing station and thence to a forward mobile hospital. In civil life this type of therapy may be compared to the first aid treatment which can be given for thoracic injuries and accidental wounds occurring in the factory, on the street and elsewhere. In industrial organizations particularly the well trained first aid man should be able to initiate nearly all the therapeutic measures here enumerated.

When the thoracic casualty arrives in a forward hospital, preliminary appraisal is made of all wounds and of the patient's general status. Since many are in too poor condition to be x-rayed at once, the correct interpretation of physical signs becomes all important. Measures of resuscitation are immediately instituted which will either prepare the patient for surgery or make him more safely transportable. As soon as possible, roentgenograms are taken and the whole problem is reevaluated. The scheme of management described here is likewise applicable to civil practice. The measures are not first aid in nature and are to be instituted in a hospital under professional guidance.

GENERAL DIAGNOSTIC CONSIDERATIONS

Physical examination of the patient includes accurate localization of the external thoracic wounds and a projection of the probable course of the missile. Roentgenograms should consist of upright frontal and lateral views of the chest whenever possible. A flat plate of the abdomen is essential, owing to the high incidence of thoracoabdominal wounds and the frequency of gastric dilatation. Oblique projections and fluoroscopy are unnecessary in the preliminary survey. Later they may be required in localizing accurately certain foreign

bodies lying in the region of the diaphragm.¹ The course of the projectile is best determined by considering the external wound, identifying fractured ribs and visualizing the metallic fragment when present. As a general rule missiles travel in a fairly straight line. Deflections from the bony cage must be taken into consideration, and foreign bodies lying free in the pleural cavity may be misleading. Other presumably bizarre courses often may be explained by reconstructing the patient's position at the time of wounding.²

By plotting the course of the missile a general idea can be gained as to intrathoracic or thoracoabdominal damage. This is one of the first steps in planning what type of surgery may be eventually necessary. The possibilities of past or future hemorrhage may be more accurately appraised. The suspicion of extensive pulmonary or cardiac contusion will counsel a delay in surgery. Pulmonary contusion may be manifested either by scattered areas of hemorrhage bilaterally such as seen in "blast" injuries or by massive bleeding involving an entire lobe or more. Cardiac injuries are not always easy to diagnose and form a special problem both in resuscitation and in surgery. A general "washed-out" condition, sustained rapid pulse, transient irregularities of rhythm and the persisting need for oxygen have been indicative signs of cardiac injury. In contrast to civil practice, tamponade has been of rare occurrence. Even the development of tamponade has not been an absolute indication for surgical intervention, as aspiration alone has sufficed on several occasions. Continuing cardiac hemorrhage is justification for an early operation. Myocardial contusion, however, constitutes a serious risk for any type of operation. The patient tolerates surgery poorly during the first few hours and undoubtedly should be handled like a patient with an acute coronary occlusion. Unless absolutely necessary, all surgery should be postponed for at least twenty-four to forty-eight hours.

Careful examination of the abdomen always should be performed on thoracic casualties. A large number of patients with uncomplicated thoracic injuries develop acute gastric dilatation; decompression must be carried out immediately. Abdominal pain, tenderness and a silent abdomen on auscultation also may be complications of a purely thoracic wound. Although frequently difficult, early decision is required as to whether these signs are due solely to intercostal nerve damage or to intra-abdominal injury. In general, the abdominal spasm which accompanies a thoracic wound is likely to be unilateral and becomes less evident on inspiration. At times the results of anesthetic block of the intercostal nerves may be of aid. Following nerve block there are often cessation of pain and skin tenderness, but in the presence of peritoneal pathologic change some degree of spasm, rigidity and tenderness to deep pressure usually remain. In most instances, however, accurate determination of the track of the missile is the deciding factor.

RESUSCITATIVE MEASURES

The clinical estimation of shock is based on a systolic blood pressure below 100, an elevated pulse, pallor (or cyanosis), sweating, a lowered skin temperature and rapid shallow respirations. In most thoracic casualties cardiorespiratory imbalance and pain are the chief elements in perpetuating shock; hemorrhage frequently

is a secondary consideration. With certain exceptions (intra-abdominal pathologic conditions, severely damaged extremities, continuing hemorrhage) there is no necessity for rushing a thoracic casualty to the operating room; often from six to twelve hours are utilized in resuscitation. In specific instances (extensive pulmonary contusion [blast] or myocardial contusion) at least twenty-four to forty-eight hours should elapse before even minor surgery is performed.

Actual resuscitation of the soldier with extensive thoracic wounds may be discussed under three headings: (I) correction of impaired cardiorespiratory physiology and relief of pain; (II) restoration of fluid balance; (III) early prevention of infection. Many of the procedures necessarily may be carried out almost simultaneously.

I. CORRECTION OF CARDIORESPIRATORY IMBALANCE

The following measures are concerned with bringing the thoracic wall, lungs, heart and mediastinum as close to a normal physiologic state as possible. Correction of cardiorespiratory imbalance frequently will bring the patient out of shock without the necessity for fluid replacement therapy.

Impairment of Thoracic Wall.—Often the first step in gaining physiologic restitution is accomplished during the first examination of the thorax. A poorly dressed sucking wound must be effectively occluded to prevent exchange of air. At the same time it may be convenient to evacuate a portion of the blood and air that have collected in the pleural cavity, particularly if the sucking wound is valvular in type. This is done by placing the patient in such a position that the wound is roughly dependent. During forced expiration and cough the wound is held open, and during inspiration the edges of the wound are approximated. Thus several hundred cubic centimeters of fluid and air may be rapidly removed. At the preliminary examination localized "flail" chest may be controlled by inducing quiet respirations through the use of regional nerve block. When flail chest and paradoxical motion are extensive, mechanical means of stabilization are necessary such as the use of small sand bags, positioning the patient with the affected side down or the use of firm adhesive strapping. Elevation of the ribs with external fixation by pericostal sutures or towel clips has not yet been necessary.

Thoracic Pain.—The relief of thoracic pain has a vital bearing on hastening recovery from shock. Anesthetic block of the intercostal nerves has proved the best means of relieving thoracic pain and has been used extensively.³ Routinely a regional type of block is employed in preference to local infiltration at the injured site. The extent and contamination of wounds have dictated the former choice. When wounds are posterior and mesial, or when regional block has not given complete relief, paravertebral injections of the same nerves are done. By this technic it is probable that both the sympathetic chain and the intercostal nerves are infiltrated. In performing regional block the area of pain is outlined and 5 cc. of a 1 per cent solution of procaine hydrochloride is injected into each nerve at the angles of the ribs. Two nerves above and two below the painful area are usually included in the injection. It is difficult to describe adequately the immediate surcease from pain which many wounded receive from this therapy

alone. A patient who has been dyspneic and grunting with pain will become quiet and may often fall asleep within a few minutes. Adhesive strapping has not been satisfactory in relieving pain due to thoracic wounds. It is now reserved solely for the stabilization of flail chest which exhibits paradoxical motion.

Morphine for the control of pain must be administered with great caution in the resuscitation ward. The observations of Beecher¹ have been verified by all who have treated fresh battle casualties. It now appears that much of the morphine given in the combat area may remain largely unabsorbed because of the slowed peripheral circulation due to shock and cold. During resuscitation quantities of unabsorbed morphine may be picked up by an improving circulation. This has resulted in acute morphine intoxication on a number of occasions. Similar occurrences may be expected in civil practice. In thoracic casualties particularly, overmorphinization has a deleterious effect in depressing respiration and dulling the cough reflex. When morphine is indicated for shock patients it should be given intravenously in doses not to exceed $\frac{1}{8}$ to $\frac{1}{4}$ grain (8 to 11 mg.).

Anoxia.—In patients with extensive thoracic wounds severe degrees of anoxia are made manifest by extreme restlessness, apprehension, sustained rapid pulse and dyspnea with or without cyanosis. Thoracic pain is often a contributory factor. Anoxia usually has been due to a combination of causes; reductions in vital capacity, anemia and cardiac injury. Again, morphine must be used with caution if at all, since respiratory depression will increase the anoxia. Pain is relieved by nerve blocks; oxygen should be given at once by nasal catheter or mask at not less than 7 liters per minute. This will act as supportive therapy until the lungs can be partially re-aerated and blood administered. There must be no delay in commencing oxygen, as a manic stage of restlessness has been observed to be the immediate precursor of death in several instances. As a general supportive measure oxygen should be used early and freely on any patient who is restless or dyspneic or whose pulse remains elevated. Cyanosis is a late manifestation of anoxia, and oxygen should be administered before it develops.

Hemothorax.—This is the most frequent complication of intrathoracic injury. A large hemothorax or hemo-pneumothorax may reduce the vital capacity to dangerous levels. If the pleural cavity appears to contain more than 500 cc. of fluid or if the patient is dyspneic and there is cardiac and mediastinal shift to the opposite side, thoracentesis should be done. As much blood is removed as can easily be obtained up to 1,000 cc., or up to the point that the patient complains of tightness in his chest. If the blood is presumably uncontaminated and less than twenty-four hours old it may be used for an autotransfusion. Changes in roentgenographic and physical signs following thoracentesis will give an indication as to further bleeding. It is difficult to generalize on how much bleeding constitutes life endangering intrathoracic hemorrhage. Bleeding of such severity from the pulmonary parenchyma is exceedingly rare. We have found the following criteria to be the most reliable guides to serious continued hemorrhage: (1) a blood pressure which fails to rise with apparent adequate blood transfusion as high as 2,000 cc. or, having risen to relatively normal levels, falls again; (2) reacumu-

lation of 1,500 to 2,000 cc. of blood in the pleural cavity within twenty-four hours of the initial aspiration of a similar large amount; (3) persisting severe anemia in spite of blood replacement, as determined by serial hematocrit readings.

Excessive Bronchopulmonary Fluids.—"Traumatic Wet Lung."²—Inadequate tracheobronchial evacuation of excessive secretions and blood has been observed in varying degrees of severity from a few hours up to seven days after injury. Wet lung is a frequent complication of thoracic trauma and has occurred following fractured ribs, parietal and intrathoracic wounds and pulmonary blast injuries. During the immediate post-traumatic period the complication may be serious and, when unrecognized, has been directly responsible for death. Its presence always increases the surgical risk. The most common symptom is a frequent "wet," painful cough. Oral wheezes are prominent and rhonchi are heard constantly over one or both sides of the chest. The cough is non-effective in that only small amounts of sputum are raised and the bubbling character of the respirations persist. Blood and tenacious mucus form the bulk of the obstructing fluid. Purulent exudate signifies a preexisting bronchitis. Acute massive collapse of the lung has been seen only twice. On both occasions it was due obviously to obstruction of a main bronchus.

The aim of treatment is to improve bronchopulmonary drainage. Any surgery ordinarily should be postponed until an adequate airway can be maintained. Morphine in large amounts and sedative cough mixtures are expressly contraindicated. Thoracic pain is relieved by nerve block³ and voluntary cough is urged. Oxygen is given if the patient's pulse remains elevated or if he becomes cyanotic. Should the patient be unable to cough effectively because of physical exhaustion, or should excretions continue to flood the bronchi overwhelmingly, mechanical suction is resorted to without delay. Either tracheobronchial catheter aspiration⁴ or bronchoscopy is employed. Suction may be necessary at hourly intervals. A catheter may even be left indwelling in the trachea and oxygen administered through it between aspirations. Catheter suction is a valuable procedure in that the materials are readily available, the technic is simple and no topical anesthesia is required. Bronchoscopy is more efficient and may be performed twice daily without ill effect. If the secretions are frothy and fine rales are heard, intravenous atropine in doses of $\frac{1}{400}$ grain (0.65 Gm.) may be beneficial. In such cases oxygen given under positive pressure also has been of value.⁵

Pressure Pneumothorax.—While infrequent, this complication may be serious and even fatal if unrecognized. The diagnosis is based on the findings of dyspnea with or without cyanosis, a hyperresonant hemithorax, absent breath sounds and a shift of the heart and

mediastinum to the opposite side. The most frequent acute traumatic cause of pressure pneumothorax is pulmonary laceration in which the bronchial opening acts as a check valve. During inspiration gradually increasing amounts of air are trapped in the pleural cavity. Pressure pneumothorax may result from the ingress of air through the thoracic wall in patients with sucking wounds. As already described, this may be relieved easily when the wound is dressed. A third but rare type of pressure pneumothorax develops as the result of small perforating wounds of the subglottic larynx or cervical trachea. Air dissects along the fascial planes of the mediastinum and may break into one or both pleural cavities. In these cases an early, low tracheotomy to short circuit the air stream is mandatory.

In the purely emergency treatment of any pressure pneumothorax a large-bore needle should be inserted in an upper anterior intercostal space and attached to a water-trap bottle. A short transfusion cannula with attached flange is excellent for this purpose. The needle should not be left indwelling for more than a few hours. If air continues to bubble through the water-trap system or, if examination shows that the lung is not expanding, a No. 16 to 18 catheter is to be substituted for the needle. The tip of the catheter is inserted just within the pleural cavity and likewise attached to a water seal. The lung will expand only if the caliber of the drain is larger than the caliber of the bronchial opening; frequently the catheter will be successful in controlling the pneumothorax when a needle has failed. No patient with pressure pneumothorax should be transported with a needle in his chest or with any type of attached water-trap drainage. When evacuation is necessary a flutter valve (long penrose tubing or condom with small distal slit) is attached to the catheter.

Mediastinal Emphysema.—This condition occasionally has been diagnosed roentgenographically. The most frequent clinical sign is the presence of a precordial crunch or click which is synchronous with the heart beat. In our experience it has not been of clinical significance and no case of increased mediastinal pressure has developed. Mediastinal emphysema has followed wounds of the hilar bronchi, trachea and subglottic larynx. Control of the pressure pneumothorax which almost always complicates these injuries has stabilized the patients sufficiently to permit operation. Suprasternal incisions into the deep fascial planes might rarely be necessary as an emergency measure. The absence of old pleural disease and the lack of pleural thickening and adhesions in nearly all individuals in the Army probably explains the ease with which air in the mediastinum dissects into the pleural cavity.

II. FLUID REPLACEMENT

For the most part intravenous therapy is limited to blood; plasma may be started at once while blood is being cross matched. Serial red cell counts and hematocrit readings have been of value in determining the degree either of anemia or of hemoconcentration, and the response to replacement therapy. Intravenous crystalloids are employed but rarely and only when there is evidence of dehydration. Besides laboratory findings, the amount of blood given is based on the patient's improvement following the first 500 cc. and on the minimum known loss (thoracentesis). Unless there has been obvious exsanguination it is better to slow the rate of administration after rapidly giving the first 500 cc. Occasionally a continuous transfusion of 1,500 to

2,000 cc. is necessary, but this should be given over a period of hours. Large transfusions rapidly administered are not well tolerated by an injured lung or heart. This is particularly true of severe pulmonary blast; in some instances the flooding of these patients with blood has precipitated acute pulmonary edema and thus become an undoubted factor in the fatal outcome.

III. THE EARLY PREVENTION AND CONTROL OF INFECTION

All battle wounds are contaminated wounds. This is equally true of compounded injuries which are incurred in civilian life. In either situation the prevention of infection is highly desirable, particularly when the wound or injury communicates with the pleural cavity. It has been routine practice to "dust" battle wounds with sulfanilamide in the combat area, and many soldiers have taken 3 or 4 grams of a sulfonamide orally before arriving at a forward hospital. Unfortunately it is impossible to say that sulfonamide therapy has materially reduced the percentage of early wound infections. Although the incidence of generalized sepsis is low, soldiers whose initial surgery has been unavoidably delayed still present an appreciable number of infected wounds. At present, all but those with minor wounds receive penicillin on admission to a forward hospital. It is given intramuscularly every three hours. If the patient is septic on arrival the initial dose is given intravenously. If there is evidence of early intrapleural infection penicillin is instilled into the pleural cavity at least once during the period of resuscitation. While believed an important adjunct, chemotherapy has not been accepted as a substitute for adequate initial excision of devitalized tissue by surgeons in the Mediterranean theater.⁹

Careful handling of the wound in a forward hospital is a factor in the prevention of infection. While it is frequently necessary to examine thoracic wounds preoperatively, several changes of dressings by different individuals must be condemned. A single inspection under sterile precautions nearly always suffices. When reapplied the dressing should not be so large that it will be disturbed by thoracentesis or subsequent examinations of the thorax.

SUMMARY

1. A rational plan has been adopted for the early preoperative care of the severe thoracic casualty in forward hospitals.

2. This program is applicable whether one is dealing with war wounds or with the thoracic injuries and wounds which may be encountered in civil and industrial practice.

3. Adequate resuscitation is a necessary preparation either for surgery or for transportation. Unless hemorrhage or the urgency of other wounds dictates early surgical intervention, the majority of serious thoracic casualties will be greatly benefited if they are not rushed to the operating table.

4. Patients with extensive contusions of lungs or heart are poor risks, and surgery in these patients should be delayed whenever possible.

5. Methods of resuscitation are (1) restoration of normal thoracic physiologic conditions including the control of pain and the treatment of hemothorax, "wet

⁹ Churchill, E. D.: The Surgical Management of the Wounded in the Mediterranean Theater at the Time of the Fall of Rome, *Ann. Surg.* 120: 268 (Sept.) 1944.

lung," anoxia and pressure pneumothorax, (2) fluid replacement and (3) early prevention of infection.

6. Oxygen should be freely used, preferably before cyanosis develops, for any patient who is restless or dyspneic or whose pulse remains elevated.

7. Caution should be observed in the administration of morphine in the resuscitation ward.

8. The "therapeutic triad" most commonly employed for improving thoracic dysfunction consists of nerve block for the control of pain, thoracentesis and water-trap catheter drainage for intrapleural pathologic changes and mechanical suction (catheter aspiration, bronchoscopy) for the removal of excessive bronchial fluids.

CONCLUSIONS

The development of an integrated system of "thoracic" resuscitation in forward hospitals has paid excellent dividends in lives saved and morbidity reduced. We would be remiss if much of the information thus gained was not applied to the solution of similar problems in civilian practice. Early contact with many wounded soldiers has served to emphasize the fact that clinical shock is perpetuated by disturbances of cardiorespiratory equilibrium. Continued experience has strengthened the concept that patients with severe thoracic wounds should be resuscitated thoroughly, that time itself plays an important role and that, with few exceptions, nothing is gained and often much is lost by hurriedly submitting the thoracic casualty to the surgeon's knife.

PARTIAL OR INCOMPLETE DELIRIUM

MAJOR MAX LEVIN

MEDICAL CORPS, ARMY OF THE UNITED STATES

My first object in this paper is to describe a particular variety of delirium, one which differs from other varieties in the extent of the patient's disorientation: Whereas in other varieties the patient is disoriented in the three spheres of time, place and person, disorientation in the variety to be described is restricted to, or is most pronounced in, the sphere of time. Reasons will be given for regarding this variety as a rudimentary form of delirium, a "partial" or incomplete delirium, while that with disorientation in all three spheres is a severe or complete delirium. My second object is to show that in partial delirium the restriction of disorientation to the sphere of time is not a capricious and incomprehensible phenomenon but is understandable in the light of Hughlings Jackson's theories of nervous function and is indeed an especially clear illustration of the merit of those theories.

Three cases will serve as examples of partial delirium. It is needless to give complete clinical histories; the relevant details alone will be given:

CASE 1.—A man aged 56, while taking bromide for a mild depression, became delirious and was admitted to a mental hospital on April 10, 1934. The history, the findings and the outcome were typical of a bromide delirium.

At no time was he observed to be disoriented for place or person, and after his recovery he could not remember having ever been disoriented in these spheres. By contrast, there was conspicuous disorientation for time. Thus on April 12, 1934 he gave the date as March 12, 1934 and said he had

been in the hospital ten days (really only three). On April 20, when asked to give the year, he replied doubtfully "35, I guess"; when asked the month, he replied "May, ain't it?—the middle"; when asked the time of day, he said "It must be getting toward evening," though it was only 9 a. m. He recovered on or about April 22.

In case 1 disorientation was restricted to time. In cases 2 and 3 it was not restricted to, but was most pronounced in, that sphere.

CASE 2.—A woman aged 20, developing a bromide delirium while under treatment for a mild depression, entered the hospital on Sept. 1, 1937. She recovered on or about September 10.

At no time did she show disorientation for place. Disorientation for person was shown at home but never in the hospital. Disorientation for time, however, was present to an extraordinary degree, as in the following examples:

September 4: She thought it was May or June. She could not give the time of day; she guessed it was 3 or 4 p. m. and thought she had already had her lunch, though actually it was only 11 a. m. Questions pertaining to time confused her to an extreme. Though it was only her fourth day in the hospital, she estimated the length of her stay as "two or three months." When asked her age, she replied in a puzzled tone "About 4,000 years— (correcting herself) —26 or 28—30 years. . . . I don't know, I'd be about 4,000 years old, I guess."

September 8: She thought she had been in the hospital "about a month." She gave the date as Sept. 15, 1938.

September 9: She gave the day, the month and the approximate day of the month correctly but still thought it was 1938.

September 10: She was now well oriented. When asked the year she smiled and said "It's not '38 yet," remembering and deprecating her previous mistakes in this respect. With amusement she recalled thinking she was 4,000 years old and said "I imagined I was the oldest woman in the world." Before her admission she had been reading about Cleopatra, and she thought this must have been in the back of her mind.

CASE 3.—A woman aged 65 with cerebral arteriosclerosis was admitted to the hospital on Feb. 6, 1935 in a bromide delirium which cleared up a little over a month after admission.

Orientation for place was never disturbed. Orientation for person was disturbed only in the first few days in the hospital and then only occasionally. But orientation for time was strikingly poor. On February 9 she said it was the middle of January 1934. Though it was only her fourth day in the hospital she said she had been there "three or four weeks." On February 14 she gave the month correctly but gave the year as 1900. On February 20 she said it was February 24; in trying to give the year she said "It's nineteen hundred and ——" and could not finish. On March 4, when she seemed much brighter, she gave the month correctly but said it was "about the 30th"; when asked the year she replied uncertainly "Is it 1935?" On and after March 15 she was clear and kept track of time without trouble.

Study of these and similar cases leads one to the conclusion that partial delirium is of a piece with complete delirium, from which it differs only in degree. In partial just as in complete delirium the patient is lacking in alertness and is restless, apprehensive, deluded and hallucinated. The toxemias and other causes of complete delirium are found also in partial delirium.

Since partial delirium appears to be a rudimentary delirium, the question arises: Does the former ever occur as a preliminary stage in the evolution of a complete delirium? Evidence on this point is hard to get, since the physician confronted with a case of partial delirium must try to cure it rather than allow it to advance. But if there is scant opportunity to study

the waxing of delirium, there is ample opportunity to study its waning. Such study shows that the completely delirious patient, in recovering, sometimes passes through a clearly definable period of partial delirium; this is shown by cases 4 and 5:

CASE 4.—A man aged 76, a heavy drinker, was admitted to the hospital on Nov. 13, 1935 in a severe delirium brought on by cardiac decompensation and by morphine taken to allay certain nervous symptoms which had followed the sudden withdrawal of alcohol. On admission he was disoriented in all spheres. In recovering he became oriented for place and person over two weeks before he became oriented for time. On November 16 he became permanently oriented for place and person. Yet on November 19 he gave the year as "36." Next day he could not give the month or year. On November 27 he gave them as January 1996. On November 29, when asked the year, he replied "It's '29—oh wait, no, that's wrong—well (helpless and embarrassed), I give it up." On December 4, for the first time, he was fully clear and remained so ever after.

CASE 5.—A man aged 85 was admitted to the hospital on Feb. 1, 1936 in a complete delirium, the immediate causes of which could never be established with certainty. The case is none the less instructive because of the order in which the symptoms disappeared in the course of his recovery. On February 4, his fourth day in the hospital, he became oriented for place and person and remained so ever after. By contrast, orientation for time was not restored until at least twenty-two days later. Thus on February 4 he said it was the end of February 1919. On February 17 he gave the year as 1937. On February 26 he gave the date as March 2, 1836. He was not questioned again as to time until March 18 when he gave the date as March 16, 1936, which is within normal limits. Thereafter he remained clear.

Cases 4 and 5 show that in recovering from a complete delirium some patients become oriented for place and person long before they become clear as to time. This of course does not happen in every case, for in many cases orientation is restored in all three spheres simultaneously. It is significant that patients 4 and 5 were very old, 76 and 85 respectively. This may explain why their recovery was so gradual. One of the signs of old age is a reduction in the speed with which the brain rallies from the effects of a poison. Hence in a group of elderly people recovering from delirium some cases may offer a "slow motion picture" of the process of recovery.

The following conclusions have been reached: There are two degrees of delirium—complete (with disorientation for time, place and person) and partial (with disorientation restricted to, or most pronounced in, the sphere of time). Partial delirium appears to represent an intermediate stage in the evolution of complete delirium; when it occurs, it may be taken for granted that the patient will in the course of time become completely delirious (provided, of course, the causes of his delirium have not been checked).

PATHOGENESIS OF PARTIAL DELIRIUM

Why, in partial delirium, should the sphere of time bear the brunt of the disorientation? Light is thrown on this question by Hughlings Jackson's theory of the relative vulnerability of the more complex nervous functions. Jackson showed that, in disease of the nervous system, functions are vulnerable in proportion to their complexity: of the functions represented in a diseased area, the most complex are the most easily disturbed.

The recognition of time is a more complex function than that of place and person. The manner of determining the complexity of a function need not be discussed fully here; reference is made to an earlier paper.¹

One criterion, however, may be mentioned: Lateness of appearance is one measure of the complexity of a nervous function. As the brain matures, higher and higher pathways are laid down, and, correspondingly, more and more complex functions and abilities make their appearance. As every parent knows, children learn to recognize places and persons long before they learn to keep track of time. This is in keeping with the relative difficulty of these tasks. For one thing, persons and places are concrete—they can be seen and touched—while time is abstract. For another, persons and places seldom change, if ever, while time on the other hand is never constant; a particular person is always "Mother," a particular building is always "Jimmie's house," but today is not always Monday. To comprehend an abstract ever changing thing like time presupposes a higher degree of cerebral growth than to recognize concrete and relatively immutable things like places and persons.

It is therefore possible to understand why, in partial delirium, it is the sphere of time that bears the brunt of the disorientation. Orientation for time, the most difficult and complex of the three varieties of orientation, is for that reason the most easily disturbed. The last to be acquired, it is the first to be lost and the last to be regained.

SUMMARY

There are two degrees of delirium, complete and partial, the difference being in the extent of the patient's disorientation. In complete delirium there is disorientation in the three spheres of time, place and person; in partial delirium disorientation is restricted to, or is most pronounced in, the sphere of time. Partial delirium appears to represent an intermediate stage in the evolution of complete delirium; when it occurs, it may be taken for granted that the patient will in the course of time become completely delirious, provided the causes of his delirium have not been checked.

The recognition of time is a more complex function than that of place and person. Therefore the relative ease with which orientation for time is disturbed is in keeping with the teachings of Hughlings Jackson, viz. that in uniform dissolution of the nervous system functions are disturbed in proportion to their complexity, the most complex being disturbed first and most.

ABSTRACT OF DISCUSSION

DR. JOHN C. WHITEHORN, Baltimore: Major Levin has called attention to the special difficulty of keeping oriented in time—a difficulty which is demonstrated in his clinical case records by the occurrence of temporal disorientation in mildly delirious patients. He pushes his generalization to an unconfirmed absolute in stating that "it may be taken for granted that the patient (temporally disoriented) will in the course of time become completely delirious, provided the causes of his delirium have not been checked." While disorientations as to time, place and person, when demonstrated, are clear and simple clinical indications of delirium, one encounters not infrequently mildly delirious patients whose delirious condition is manifested, not in clearly describable disorientation, but in misinterpretations of complex situations and inaccurate identifications, apparently determined in part by emotional attitude. Is it the author's intention to brush aside such clinical complexities in favor of a sharply simplified neurologic schematization? If so, then he is proposing essentially a simplified redefinition of delirium. The material presented is suggestive but does not appear to me adequate to establish the utility or validity of such a redefinition.

1. Levin, Max: Degrees of Automatic Action: Some Psychiatric Applications of Hughlings Jackson's Concept of "Reduction to a More Automatic Condition," *J. Neurol. & Psychopath.* 17: 153-175, 1936.

DR. WINDRILL MUNCH, Baltimore: Dr. Levin has called attention to a clinical phenomenon often enough encountered; namely, the increased frequency with which time disorientation occurs relative to place and person disorientation. His explanation that orientation for time is more complex and more recently acquired developmentally than are the two other varieties of orientation would seem to fit in with the facts of child development. That this presupposes a higher hierarchy of functions in the Hughlings Jackson sense does not follow. The child orients himself for person and place perhaps because these items are more loaded with symbolic significance for his welfare, in the terms that he recognizes that function to be. Actually "time" to the infant is an item in the essential bodily rhythms of waking—sleep, quiescence and peristalsis, and so on, thus having a function as an integral part of the vegetative processes. Probably because of this it comes to have symbolic value as an element in orientation only late in development and then to a large extent by the impression from external sources of the need and desirability of order. In these senses, then, place and person orientation may be the more firmly grounded because it appealed to and fitted in earlier and more strongly with the infants' psychobiologic needs. Direct recognition of this fact may be further seen in the care given to all sorts of hospital patients—as well as delirious ones—namely, we attempt to further the sense of security of the patient by providing him with a relatively constant environment. We do not change rooms and nurses frequently if it can be avoided. It is less important to have a clock and a calendar in the patient's room. All this argument may offer only a teleological explanation of what Hughlings Jackson postulated in neurologic terms. What may be said for those patients who show disorientation for self (with parts of the self) and/or others, for place, but in whom time appreciation is relatively unimpaired? According to the best information to date, such disturbances follow on localized lesions and are related to the classic agnosias and apraxias. This gets into a most complicated field, far from being satisfactorily explored. As far as I know, time appreciation has never been so linked with the agnosias and apraxias. Perhaps Hughlings Jackson would say this offers only further proof of his contention that the earlier the functional development, the more basically is it laid down in structure. The concept of delirium basically rests on demonstrable clouding of consciousness with difficulty in grasp. Disorientation then is only one of several features. Accordingly, the title of the paper might better have been "Delirium with Partial and Selective Disorientation"

Clinical Notes, Suggestions and New Instruments

RECURRENT HEADACHE RESULTANT FROM MALARIA

COMMANDER ABRAHAM KAPLAN (MC), U.S.N.R.

Headache is a common symptom, due to many causes. This report focuses attention on a type of headache which will present itself with increasing frequency as more of our personnel who served in the Pacific combat areas are demobilized.

REPORT OF CASE

History.—C. B. R., a Marine corporal aged 36, was admitted to sick bay because of recurrent headaches. As a youngster he was knocked out while boxing and fainted once a few days later. When he was 17 years old he enlisted in the U. S. Marine Corps and two years later was given a BCD (bad conduct discharge) for falling asleep at his post while on guard duty. In April 1942 he reenlisted in the U. S. Marine Corps fifteen months after the second enlistment he was transferred from a ship to a nearby hospital ashore because of pain of the right arm of two months' duration. At the hospital it was learned that when he was 12 years old he was struck with a rifle over the right upper arm and since then a "lump" remained

at this site. The "lump" gave him no trouble until two months previously, when he first discovered pain and discomfort on motion. Examination showed a firm, moderately tender tumor about 10 cm. in diameter at the upper end of the right humerus. The tumor seemed attached to the bone but in no way interfered with motion. X-ray films of this region showed a bony growth about 8 cm. in length distal to the articular surface of the head of the humerus. It had the appearance of a benign osteochondroma. After one week in the hospital the symptoms subsided and he was discharged to duty.

Present Illness.—In December 1943 he was admitted to the ship's sick bay in a delirious condition. It was known that he had consumed large quantities of alcohol. He was given 3 grains (0.2 Gm.) of amytal and transferred to a nearby hospital ashore. On the following morning he was fully oriented and freely admitted drinking alcohol to excess but denied being addicted to liquor. For three weeks he had been troubled with occipital headaches which were so severe that he was unable to sleep and to get some relief he took to drink.

Physical and neurologic examinations were completely negative. The spinal fluid studies showed an initial pressure of 175 mm. There was no evidence of block and no increase in cells, sugar, chlorides or protein. The blood and spinal fluid Kahn tests were negative. Other laboratory studies, including x-ray of the skull, were negative. X-ray films of the mandible, however, showed suspicious rarefied areas in the region of the second and third molars. These teeth were extracted, but the extractions did not result in any improvement in the headaches. Repeated eye, ear and sinus examinations failed to reveal any pathologic condition that could account for the severe occipito-vertex headaches. Routine blood studies as well as studies of blood calcium, blood phosphorus and sedimentation rate were negative. The basal metabolic rate was minus 15. Dehydration did not influence the severity or the frequency of the headaches. Check x-ray studies of the right humerus showed no evidence of any malignant change. After two months of hospital study, observation and treatment, during which time there was no subjective improvement, the patient requested that he be returned to duty. He was therefore discharged.

He returned to his station and after five days' trial of duty he was found to be of little value to his command. During this interval the headaches continued unabated; he became dejected and morose and stayed awake almost all night. He was therefore returned to the hospital for further investigation and disposition.

Examination again failed to show any abnormal physical or neurologic signs. The psychiatrist made the following note: "The patient is not as alert as he was several months ago. He seems to have deteriorated in his emotional fields and shows psychomotor retardation but no true depression. The case is a complicated one, presenting schizoid features but not manifest dementia precox. He is unfit for duty. The condition may be an incipient psychosis, but there is insufficient evidence at hand at this time to make such a diagnosis. I suggest the diagnosis of psychoneurosis, war neurosis, and recommend transfer to a hospital on the mainland for disposition."

While waiting for transfer it was noted that the patient rarely smiled, took little interest in his surroundings and spent most of his time in his bunk. Two months later he arrived at a hospital on the mainland.

He still complained of headaches, but they did not seem so severe. Repeated physical and neurologic examinations as well as laboratory studies were negative. The report of his mental status was as follows: "The patient has definite psychomotor retardation; he is listless, introverted and emotionally unstable. He has an earnest desire to remain in the service but has demonstrated a lack of energy and determination to fulfil this desire when it was granted on a previous occasion. The patient appears dejected and unhappy, but no depression is manifested. It is questionable whether this man can adjust himself even to limited duty, but, if observation warrants, a try at limited duty is recommended."

The patient was granted one month leave. He returned anxious to go back to full duty and was therefore granted another try.

This article has been released for publication by the Division of Publications of the Bureau of Medicine and Surgery of the U. S. Navy. The opinions and views set forth in this article are those of the writer and are not to be considered as reflecting the policies of the Navy Department.

For nine months during his stay on the mainland he managed to carry on his duties in spite of recurrent headaches. He was then returned to the Pacific area, where the headaches continued for eight months and during the month before admission they became increasingly severe. For six months he lost weight steadily. Ten days before admission he started to have chills and fever recurring every second day.

A malarial smear was positive for *Plasmodium vivax*. The patient was given a thorough course of quinine and atabrine, with complete disappearance of the chills and fever and for the first time in years complete disappearance of headache. The diagnosis was chronic malaria.

COMMENT

The experience here described is not altogether unusual and has been reported in detail to illustrate the false leads that may be encountered in a similar case. Although detailed blood studies were made repeatedly, a smear for malaria was unfortunately overlooked. Malaria in the Pacific area is a common disease and will become much more common in the United States as more of our fighting men return from the zones where they were exposed to the *Anopheles maculipennis* mosquito. Malaria is also a "great imitator," and it will have to be included with greater frequency in the differential diagnosis of many diseases.

The finding of the malarial parasite in the circulating blood of a patient does not necessarily rule out other causes of disease. A negative blood smear or even several negative blood smears for malaria in a patient who has had or was exposed to malaria does not rule out the existence of the malarial parasite. During the past year we have had at least a dozen patients presenting only the symptoms of recurrent headaches in whose blood we repeatedly failed to find the plasmodium in carefully prepared blood smears. In these patients the administration of quinine sulfate 15 grains (1 Gm.) or epinephrine 2 minims (0.12 cc.) subcutaneously invariably resulted in the appearance of the malarial parasite in the blood stream within two to four hours after the medication was given. A blood smear taken during this interval clinched the diagnosis.

Council on Foods and Nutrition

SPECIAL ARTICLE

The present lack of agreement concerning the value of vitamin administration has indicated the need for an authoritative discussion on the use and abuse of vitamins. At the request of the Council Dr. Norman Jolliffe, a competent authority in this field, has prepared this report describing the proper use of vitamin preparations and commenting on practices which tend to bring them into disrepute.

GEORGE K. ANDERSON, M.D., Secretary.

THE PREVENTIVE AND THERAPEUTIC USE OF VITAMINS

NORMAN JOLLIFFE, M.D.
NEW YORK

Commercial exploitation of recent advances in the science of nutrition has led to some misinformation and confusion of the public concerning the proper use of vitamins. The author of a magazine article¹ has noted the bewilderment of laymen by dozens of mutually contradictory statements offered as proof that this or that vitamin preparation is better than all others. When a person buys a vitamin product as a panacea, it makes little difference whether he does so because of unbounded claims over the radio, in newspaper or magazine advertisements, syndicated health columns or magazine articles or by a druggist, a doctor or a friend;

the expected miracle often fails to materialize. The resulting disappointment, multiplied many thousand times, may lead to a loss of public confidence and the eventual rejection of the good in scientific nutrition as well as the bad in its exploitation. Already there are indications that interest and faith in nutrition have begun to wane. Thus many editors, always sensitive to the public whim, are now jumping on the debunking band wagon by attacking indiscriminately both the good and the bad in the nutrition program.

Many people, with profit to themselves, turn to their physicians for advice on nutritional problems. Too often, however, the patient is further confused by such impatient counsel as "This nutrition stuff is the bunk"; "Vitamins are a racket"; "You eat a good diet, don't you?—Eat three square meals a day, including plenty of milk, meat, vegetables and fruit"; "Oh, take a vitamin capsule every day—any one, they are all the same." This type of injudicious advice may be more damaging to good nutrition than misinformation over the radio, since more people have faith in their physician than in a radio commercial. Sound information about the role of vitamins in nutrition thoughtfully presented can be the physician's valuable ally in maintaining his patients' health.

TABLE 1.—Supplementary Vitamin Mixtures

Vitamin A.....	4,000-5,000	international units
Vitamin D.....	400-800	international units
Thiamine hydrochloride.....	1-3	mg.
Riboflavin.....	2-3	mg.
Niacin.....	10-20	mg.
Ascorbic acid.....	30-100	mg.

Vitamin preparations may be divided into two large groups: the supplementary and the therapeutic. The supplementary preparations are those which, in the recommended daily doses, provide amounts of specific nutrients below therapeutic levels but sufficient as dietary supplements to insure an adequate intake of the specified nutrients. As a rule the formulas of the supplementary preparations supply in one dose or in divided doses the amounts of vitamins suggested in table 1. Whether a formula supplies the minima or the maxima of these levels, the indicated usage remains the same, that is, supplementary to the diet. The therapeutic vitamin preparations are those that provide levels in which the daily doses are sufficiently large to be of value in the treatment of deficiency diseases. These levels are usually three to five but may be ten or more times the minimum daily requirements. Supplementary as well as therapeutic preparations may consist of a single vitamin or combinations such as vitamins A and D, the B vitamins, the water soluble vitamins or a multiple vitamin formula of both water and fat soluble vitamins.

INDICATIONS FOR PRESCRIBING SUPPLEMENTARY LEVELS OF VITAMINS

The supplementary levels of vitamins are of use in helping to prevent diseases due to deficiency of the nutrients contained in the supplement. As listed in table 2, indications for such use occur whenever the diet is unsatisfactory from any of a variety of causes or when there is an increased requirement for vitamins. The supplementary formulas are definitely not appropriate when the patient has already developed a deficiency disease, as much higher levels are usually required for effective therapy.

1. Cunningham, R. M., Jr.: The Great Vitamin Scare, New Republic 112:287 (Feb. 26) 1945.

The physician will have little difficulty in recognizing the necessity for supplementing restricted or special diets and in infant feeding. Many, however, do not possess the time, inclination or information necessary to calculate a diet in terms of grams, milligrams or units of protein, minerals and vitamins. For most ordinary purposes this calculation is not necessary if a list of food groups, as shown in table 3, is used to check whether or not the patient eats at least the indicated minimum from each of the groups. A diet lacking in one or more categories, unless specially devised by an expert dietitian, is almost certain not to contain the National Research Council's recommended allowances of one or more of the essential nutrients. On the other hand, even the inclusion of a serving from each of the seven food groups does not definitely assure that the diet will be adequate. The check list is intended only as the simplest kind of guide for planning a satisfactory diet, and it should not be regarded as infallible. Not

ing in other essentials than vitamins alone, for those people who do not or cannot regularly consume a satisfactory diet a proper vitamin supplement is indicated. While this is not as good as a completely satisfactory diet, it is the next best thing.³

INDICATIONS FOR PRESCRIBING THERAPEUTIC LEVELS OF VITAMINS

The therapeutic levels of vitamins are of use in the treatment of vitamin deficiency diseases and as drugs.⁴ Successful treatment of nutritional deficiencies involves many factors other than giving vitamins: It involves careful diagnosis, the treatment and whenever possible elimination of conditioning factors, symptomatic treatment and finally the administration of nutritional therapy in sufficient amounts and over a sufficient period of time to evoke maximum reversal of the nutritional lesion.

The diagnosis of deficiency disease is frequently missed because it is not looked for. Nutritional deficiencies should be suspected in the following groups of persons:

1. Those whose diets indicate possible deficiencies.
2. Those who have conditioning factors known to increase the requirement, destruction or excretion of vitamins or to interfere with their digestion, absorption or utilization.
3. Those complaining of certain symptoms which, while not diagnostic, are often associated with deficiency disease.

The mere fact that a person falls into one or more of these groups does not in itself justify the diagnosis of a nutritional deficiency disease. That is made only in the presence of anatomic, chemical or physiologic alterations characteristic of deficiency disease which have been evaluated in the light of the history and of clinical and laboratory findings.

Adequate nutritive therapy does not consist in giving only the nutrients in which a deficiency is clinically manifest. It is now known that most deficiency states involve multiple factors, and deficiencies clinically evident are usually associated with additional tissue deficiencies of nutrients not yet clinically manifest. Adequate therapy of a deficiency disease, therefore, requires not only sufficient administration of the specific nutrient long enough to obtain maximum reversal of the manifest lesion but also, in addition, the restoration of tissue normal in all the essential nutrients. This can best be accomplished by a judicious combination of diet, a source of the whole vitamin B complex, the essential^{4a} vitamins (vitamin A, D, B₁, B₂, C and niacin amide) and specific therapy. A good diet means a full, nutritious, protein rich diet including natural unrefined foods administered within the tolerance of the patient. The good diet is essential, for it contains, along with known nutrients, unknown factors which cannot yet be encapsulated or dispensed in drops, ampules or tablets. In addition, the prescription of an adequate diet is a means of educating the patient of its value in the hope that he will continue it when other therapy is discontinued.

3. Some authorities apparently feel that a vitamin supplement may conflict with obtaining the best possible dietary. This is not necessarily or even usually true. It should be noted that the increase in vitamin sales between 1939 and 1944 coincided with, and did not prevent, a decided improvement in the per capita American diet. It may be that vitamin supplements call to the attention of their users the importance of a satisfactory diet.

4. The use of vitamins as drugs will not be dealt with in the present article.

4a. By essential vitamins is meant those recognized by the Food and Drug Administration as dietary essentials in human nutrition.

TABLE 2.—*Indications for the Use of Supplementary Vitamin Formulas*

1. To supplement:
 - (a) An unsatisfactory diet in the part of the general population that will not or cannot eat a satisfactory diet, or for those whose diets do not appear to be satisfactory.
 - (b) Restricted diets, as in obesity, diabetes, gallbladder disease, peptic ulcer and food allergy or during illness, infections or some surgical conditions and in convalescence.
 - (c) Special diets for food faddists.
 - (d) Infant feeding.
2. For persons known to have an increased vitamin requirement, as in hyperthyroidism, pregnancy, lactation, fevers and delirium or during periods of unusual physical exertion.

TABLE 3.—*Check List for a Satisfactory Diet*

Include at least:

- (1) 4 eggs weekly.
- (2) 1 serving daily of citrus fruit, tomato or their juices, or fresh uncooked salad greens.
- (3) 1 quart of milk daily for children, with an extra source of vitamin D.
1 pint of milk daily or its equivalent in cheese, for adults
- (4) 1 serving daily of lean meat, fish, poultry or seafood.
- (5) 1 serving daily of a cooked leafy green or yellow vegetable.
- (6) 1 serving daily of another vegetable or fruit.
- (7) 1 portion daily of enriched or whole grain bread or cereal.

all combinations from the seven groups will supply all the recommended nutrients. Moreover, even when the choice of combinations is originally satisfactory the diet may be rendered unsatisfactory by the destruction or loss of nutrients in cooking and serving, or by the additions of unusual amounts of vitamin deficient or poor foods such as refined cereals, sugar, many types of candy, cake and alcoholic or sweetened carbonated beverages. Practicality dictates that the physician prescribe supplementary vitamins whenever a patient is not regularly consuming a satisfactory diet. Some patients may sincerely try to eat a satisfactory diet but fail because of business, working or home conditions, or for other causes beyond their control. Others will not eat a satisfactory diet because of habits, fads or fancies, lack of necessary information² or sheer obstinacy. Even though an unsatisfactory diet may be lack-

2. The Food and Drug Administration expressed it as follows (Statement of Policy of the Federal Security Agency Under the Federal Food, Drug and Cosmetic Act, Fed. Register, July 3, 1940): "...nor are most consumers sufficiently educated on nutritional questions to enable them to make an intelligent choice of combinations of unenriched foods on the basis of nutritional values."

The entire vitamin B complex is given, preferably in the form of brewers' yeast, brewers' yeast extracts or crude extracts of whole liver, liver concentrates or desiccated liver, wheat germ or rice-bran extracts. These are not given primarily because of their content of thiamine, niacin and riboflavin but rather as a source of other B complex nutrients not yet synthesized, thus supplementing these factors as found in the full diet. Many conscientious physicians have been lulled into the belief that a dose of several milligrams of a yeast or liver fraction fortified with synthetic vitamins, in a capsule or a pleasantly flavored syrup or elixir, constitutes adequate B complex therapy. Liver and yeast products should be administered in grams and ounces rather than in grains and milligrams.

A preparation containing large amounts of the fat and water soluble essential⁴¹ vitamins is also given, as almost every manifest deficiency is associated with a multiple tissue deficiency of these vitamins. A practical formula is one containing vitamin A 25,000 units, vitamin D 1,000 units, thiamine 5 mg., riboflavin 5 mg., niacin amide 150 mg. and ascorbic acid 150 mg. The administration of this formula twice daily for a week or ten days is effectual in helping to restore normal tissue levels of these essential vitamins. After this period, administration once a day is usually sufficient.

To this basic therapy of diet, vitamin B complex and essential vitamins are added the specific chemicals indicated by the manifest nutritional diseases. Thus, if there are lesions of vitamin A deficiency, 50,000 to 150,000 international units of vitamin A is given. Similarly, for their specific lesions, 10 to 20 mg. or even 100 mg. of thiamine, 5 to 15 mg. of riboflavin, 100 to 1,000 mg. of niacin amide and 100 to 1,000 mg. of ascorbic acid are prescribed. In acute deficiency disease this treatment may be required only for days or weeks; for chronic deficiency disease treatment may be required for much longer periods.

SOME ABUSES IN THE COMMERCIAL EXPLOITATION OF VITAMINS

The confusion and bewilderment of the public and a possible incipient loss of faith in scientific nutrition are understandable when some of the promotional claims made for certain vitamin and food preparations are examined. The most prevalent abuses fall into three groups, namely therapeutic claims for supplementary levels of vitamins, failure to tell all and advertising puffery beyond a reasonable limit.

To make therapeutic claims for supplementary levels of vitamins—whether contained in enriched or natural or concentrated foods, in tablets, drops or capsules—has been held by the Federal Trade Commission⁵ as misleading. This interpretation seems to be well founded. It is granted that doses of vitamins within supplementary levels have been shown by qualified observers⁶ to have therapeutic value. It is important, however, to bear in mind the conditions prevailing in all these studies; the favorable responses were obtained in experimental subjects who were previously

well fed but had been subjected to an acute dietary deficiency of known factors for a relatively short time. Under these conditions supplementary levels have therapeutic value. In the aggregate there are probably many individuals in this country who from time to time have acute mild dietary deficiencies that will respond, within a reasonable period, to supplementary levels of vitamins. These persons, like people with a coryza, seldom consult a physician, as a few days of rest, with resulting elimination of some possible conditioning factors, a return to adequate diet or the taking of a vitamin supplement, usually results in a cure. It is, as a rule, only when symptoms persist that a physician is consulted. Just how large this group is, no one knows. Among those who consult physicians the commonest vitamin deficiencies are the more chronic ones,⁷ both mild and severe, in which supplementary levels of vitamins do not, within a reasonable period of time, cause a reversal of the nutritional lesions.

A review of the literature on vitamin therapy, especially that published since 1938, shows that almost without exception nutrition experts, to correct symptoms and signs due to vitamin deficiencies, advise and prescribe thiamine, niacin, riboflavin, vitamin A and ascorbic acid in daily doses larger than the supplementary levels. Since even physicians who are nutrition experts seldom, if ever, treat a deficiency disease with vitamin doses in supplementary levels, it does not seem to be in the public interest for therapeutic claims, no matter how qualified, to be made in advertising supplementary levels.

The failure to tell all may be a most pernicious practice in the commercial exploitation of nutrition, and one very difficult for any regulatory body or censor to deal with because what is said is carefully made to be factually true. Criticism of this practice meets the reasonable argument of the copy writer that limitations of language make it impossible, in the time or space available, to tell the entire story. This argument seems valid unless the public of average normal intelligence and information would probably be misled by the offending copy. It is recognized that any idea, even if expressed in the simplest and clearest of statements, may be misleading to some portion of the less intelligent, less informed and more gullible public. This fact should not prevent an advertiser from using a true statement which most of the public is capable of understanding without misinterpretation.

Examples of failure to tell all are numerous and include the stressing of economy of vitamin preparations as compared to food costs, incomplete quotations or lifting quotations from their context so as to give wrong implications, incomplete statistics, the enumeration of signs and symptoms of deficiency disease which vitamins will in truth prevent but without information that these signs and symptoms are not specific for nutritional disorders only and may occur as a result of nonnutritional diseases and the implication that this or that preparation will make the user more alluring to the opposite sex, except as far as the preparation will help maintain normal health. One of the most common failures to tell all is the implication that synthetic vitamins may be harmful or in supplemental levels have effects like drugs, that natural vitamins alone are effectual or that they have a value superior to

synthetic vitamins. This common implication, based on the fact that natural foods or concentrates contain values and substances other than their known vitamins, has been so misused that the Food and Nutrition Board of the National Research Council has recently gone on record to the effect that "there can be no possible difference between thiamine prepared synthetically and that which is extracted from a natural source of thiamine such as wheat or meat (or yeast). The same is true of riboflavin and of other vitamins that thus far have been synthesized. A vitamin is a chemical compound whether it is made by nature or by man."*

Advertising puffery beyond reasonable limits is another method of exploitation that is difficult to regulate; courts have held that advertising puffery, within reasonable limits, is not improper. "Within reasonable limits" may mean one thing to a regulatory body and something else to a copy man attempting to sell, in a highly competitive market, a product that is no better or no worse than a dozen other similar products. Reasonable limits include some puffing of the product based on a unique manufacturing device or on a peculiar and unique balance or unusual mixture, if in truth there

that are needed to avoid dietary inadequacies and resulting deficiency diseases. In contrast, there is fair unanimity that the National Research Council's Recommended Daily Allowances represent approximately the amounts of essential nutrients needed to insure, for population groups, a fair margin of safety in everything that food can contribute toward the long-range advancement of human welfare.

Wilder⁹ has pointed out that the daily allowances have at times been misused when it was suggested that the failure of a diet to meet these recommended quantities of nutrients is *ipso facto* evidence of dietary inadequacy or, still worse, of nutritional abnormality. This inference was unwarranted, "as the recommended allowances include a factor of safety of at least 30 per cent to provide for persons whose requirements may be greater than average. . . ." The failure of a population group to meet these requirements, therefore, does not mean that the group as a whole has an inadequate or deficient diet. It does mean, however, that the diet is unsatisfactory in that it fails to provide adequate nutrients for some persons whose requirements are in excess of the dietary intake. Since the

are advantages. Unreasonable limits would seem to be when claims are made for some vitamin or mineral whose value in human nutrition has not yet been established, to claim or imply that this or that preparation will enable a person to neglect his diet and that he will be as well as or better off than with consumption of a satisfactory diet or to claim or imply that this or that preparation will enable a normal person who always consumed a satisfactory diet to feel better. All of these inferences have been decisively exploded.

Another group of facts susceptible to much puffery by advertisers and to arbitrary decisions on the part of regulatory bodies are reports on the prevalence of inadequate diets among the general population, and claims or inferences concerning either the ease or the impossibility of the average consumer's obtaining an adequate diet from food alone.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION noted in an editorial "that there is a real difference as measured in terms of growth, development and general health record between optimum and just adequate nutrition; and that every practical effort should be made to apply this knowledge in the interests of human welfare." Much controversy exists concerning the minimum amounts of the various specific nutrients

individual usually has no way of knowing whether his needs are below average or above, and since those responsible for feeding population groups have no practical way of segregating those with nonaverage requirements, the only diet "that can be countenanced is one that provides enough for all well persons whether their requirements as related to the average are high or low."

Using the National Research Council's recommended daily allowances as criteria for a satisfactory diet, the Bureau of Agricultural Economics of the United States Department of Agriculture¹⁰ has shown that the food that disappeared into civilian retail consumption in 1944 contained after conservative deductions for waste and deterioration of ingredients in storage, transportation, cooking, leaching and serving satisfactory levels of nutrients. In 1943 the figures for riboflavin and niacin were not satisfactory. In the period 1935-1939 the available dietary levels of thiamine, riboflavin, niacin and calcium were unsatisfactory (table 4). These calculations are based on per capita consumption. It is not to be supposed that perfect distribution has ever been obtained, so that the number of people who received both above and below the per capita portions must be numerically large. Bearing out these figures of food

availability are the dietary survey records compiled by a committee of the National Research Council in 1943,⁷ which disclosed that unsatisfactory diets were widespread in all sections of this country. Later surveys made since this review of the National Research Council's committee have reflected the overall improvement in the nutrients available per capita in 1943. For example, the Bureau of Human Nutrition and Home Economics reported in 1944 that "in 1936 about three fourths of the families in the United States had diets that did not meet the National Research Council's recommendations for riboflavin; and about half had diets that were low in calcium, thiamine and ascorbic acid. It is estimated that in the spring of 1942 the diets of more than half of the families still did not meet the recommended allowances for riboflavin and that the proportion of diets low in calcium had been reduced to less than a third; the proportion low in thiamine to a fourth, and the proportion low in ascorbic acid, in which there was the greatest improvement, to less than a tenth. Some of the improved situation in respect to ascorbic acid was a result of seasonal increases in the consumption of citrus fruit and leafy greens. There was also a great reduction in the estimated proportion of families that had diets failing to meet current recommendations in vitamin A value, iron and protein, from about a fourth in the earlier period to around a tenth in the later period."¹¹ It is well to bear in mind, as pointed out by these investigators, that the estimates for both periods "are optimistic, since no correction has been made for nutrient losses in food preparation."¹¹

The American Institute of Public Opinion¹² in February 1943 made a single day nationwide survey of consumption of the seven groups of foods considered essential in a satisfactory diet as recommended by the Bureau of Human Nutrition and Home Economics. The results presented in table 5 show that a significant fraction of the American population in all economic groups fails to include all the basic foods in the daily diet. As has been pointed out, this means that the diet is probably unsatisfactory.

In a survey conducted during August, September, November and December 1943 by Lockhart and his associates¹³ actual chemical analysis was made of duplicate meals eaten by 71 individuals selected to obtain a distribution of age (above 5 years), sex, activity and economic status similar to that of the nation as a whole. By these analyses the average daily intake was found to be satisfactory in ascorbic acid, calcium and iron and unsatisfactory in thiamine, riboflavin and niacin. Only 7 per cent of the subjects, however, received a satisfactory level of all the nutrients analyzed, and all of these were children. Assuming that the National Research Council's recommended allowances included a margin of safety of approximately one third above the "protective" levels, these investigators found that 21 per cent of the subjects failed to obtain a "protective" amount of all nutrients.

Concurrently with this chemical dietary analysis a one day survey was made of the diets of 3,336 persons

in all parts of the United States. The quality of the food selection in this large group was definitely inferior to that of the 71 individuals whose diets were examined by chemical analysis. "Thus it is possible that the dietary intake of the nation at the time this study was made was even less adequate than that of the small group whose diets were analyzed."¹³ It seems therefore that, compared to the satisfactory diet, there is a high prevalence of unsatisfactory diets in all sections of this country. To take any other stand is to ignore the facts.

While it is possible, if one has the necessary information, education and income to purchase an adequate diet, it is obviously also not easy for the average person who does not know the difference between a calory and a vitamin to make this selection. This fact is borne out by the experience of investigators who have actually computed the values in dietaries consumed by those who are reasonably intelligent and have the necessary means to purchase whatever food they please.

These are the conditions on which the commercial exploitation of vitamin preparations is based and which make possible the abuses that have been described. They are also the conditions which create an oppor-

tunity for the physician to serve his patients and the public welfare by employing the advances in our knowledge of nutrition in such a way as to promote health.

CONCLUDING STATEMENT

The physician can contribute decisively to the preservation and the improvement of his patients' health by judicious nutritional advice as to satisfactory dietaries and the appropriate prescription, when indicated, of supplementary and therapeutic levels of vitamins.

Though a satisfactory diet is the best way to insure optimum nutrition, practicality dictates the use of supplementary levels of vitamins whenever a patient is not regularly consuming a satisfactory diet. When, however, signs of a dietary deficiency disease are manifest, supplementary levels of vitamins are inadequate and nutritional therapy is indicated.

The commercial exploitation of vitamins is subject to certain abuses, particularly the making of exaggerated claims, the publicizing of statements which, by failing to tell all, allow unfounded inferences to be made, and unreasonable puffery. These abuses may lead to a loss of public confidence and rejection of the good in scientific nutrition as well as the bad in its exploitation. For self interest over the long pull firms advertising directly to the public should censor their copy so that false claims or false inferences are eliminated.

SATURDAY, OCTOBER 27, 1945

NUTRITION IN THE NETHERLANDS

During the later part of the recent war in Europe the Netherlands was known to be one of the German occupied countries suffering severely from malnutrition. Reports reaching the liberated area from still occupied western Holland toward the end of last October attested to the extreme degree of food shortage and starvation existing there. Careful plans were made for a rapid survey of the nutritional status of these people by three teams of Allied nutrition experts promptly following their liberation. Stocks of special foods for treatment of the most desperate situations were imported, and fifty-one Dutch medical feeding units were organized and trained in their use.

The preliminary report on this problem of mass starvation¹ indicates the extensive ramifications of prolonged consumption of food at caloric levels of approximately 1,000 calories per day. The people complained of bodily and spiritual exhaustion. Dizziness and a tendency to collapse on prolonged standing were commonplace. Complaints of backache, leg-ache, chilliness and numbness of the extremities were frequent. Wasting and emaciation were striking in the appearance of the people. The skin was pale, sometimes with dun pigmentation of the face, and petechiae or larger superficial hemorrhages were noted on the backs of the hands. Hunger edema was not universally found but was present in about 20 per cent of those examined in a "street clinic" in Rotterdam.² This appeared most often in the lower part of the body and varied in all degrees of severity. The skin of other parts of the body at the same time often showed signs of desiccation. Objective findings sufficient to justify a diagnosis of frank scurvy, beriberi, pellagra or vitamin A deficiency were not encountered, although the incidence of purpuric manifestations, sensory changes, cheilosis and follicular hyperkeratosis was considerable. The heart was usually normal, although pulse rates often down to

40 per minute, systolic blood pressures to 80 mm. of mercury and body temperatures of 95 F. pointed to a low vitality. All of the persons seen were anemic, with hemoglobin values of about 11 Gm. per hundred cubic centimeters and a color index of 1 or slightly greater. A general osteoporosis had developed in some patients suffering from starvation. Those most severely affected had pain in the bones, and some had developed a progressive kyphoscoliosis of the upper part of the spine. In other less emaciated cases joint pains were often reported. Approximately 5 per cent of the total population of the areas examined were found to be in a serious state of undernutrition. These persons for the most part dwelt in the larger cities.

Treatment of the more severe cases consisted in absolute bed rest and conservation of body heat. Comparative observations were made on the effectiveness in initiating recovery of enzymic protein hydrolysates with and without added glucose and vitamins and a diet of high protein-moderate calory content. The hydrolysates were frequently distasteful and an aversion to them, sometimes vomiting, developed although they caused no other untoward intestinal symptoms. Psychologically the patients thought they were getting insufficient food. Hydrolysates in low concentration had little beneficial effect on the edema or apathy. Two liters of 7.5 to 10 per cent hydrolysate with an equal quantity of glucose daily had a moderately good effect. Others given 80 Gm. of protein with a 2,000 calory diet lost their edema but did not gain weight. Subsequently additional calories added in the form of 100 Gm. of butter produced a gain in weight and general improvement. The best results were obtained from a diet containing 300 Gm. of natural protein and 3,200 calories. For those who were too weak or refused to take food because of mental disturbance due to starvation the hydrolysate-glucose mixture administered by gavage was valuable for a short time until ordinary feeding could be instituted. In the hands of these nutritionists 5 per cent acid casein hydrolysate given intravenously caused thrombosis and when used alone did not secure favorable results.

Many of the complications were closely related to the extreme malnutrition and responded to generally improved nutrition rather than to specifics. Thus the severe anemias were not influenced by administration of vitamins, liver extract, injections or iron preparations with or without hydrochloric acid but slowly improved after sufficient feeding. The hemorrhagic diathesis did not respond to ascorbic acid but disappeared slowly with the general improvement. In other instances the use of such specific agents as nicotinamide for sore, red tongue and vitamin D for the bone dystrophies brought improvement rapidly.

In spite of the utilization of all therapeutic weapons in the modern scientific armamentarium for the correction of the nutritional deficits, approximately 10 per

cent of the persons requiring hospital admission died. Many in a state of shock or severe atrophy proved refractory to the use of hydrolysates or other emergency treatments. The positive as well as the negative results secured from observations made under the unusual conditions of this study contribute importantly to our knowledge of human nutrition.

VACCINATION AGAINST INFLUENZA

In April 1944 the preliminary report by the members of the Commission on Influenza on the prophylactic value of vaccination against influenza appeared in *THE JOURNAL*.¹ The virus for the preparation of the vaccine was obtained from allantoic fluid of embryonated hen's eggs inoculated forty-eight hours earlier. The virus was concentrated ten times in isotonic solution of sodium chloride following adsorption to and elution from the embryonic erythrocytes. The infectious capacity was inactivated by solution of formaldehyde in a concentration of 1:5,000. Phenyl mercuric nitrate 1:100,000 or borate 1:50,000 was then added for bacteriostatic purposes. Each cubic centimeter of the vaccine was made up of 0.5 cc. representing type A virus recovered from 5 cc. of allantoic fluid and 0.5 cc. representing the type B virus recovered from 5 cc. of allantoic fluid. The type A component represented equal parts of the PR8 strain and of the Weiss strain, isolated in May 1943. The type B component contained only the Lee strain. The study was carried out in Army Specialized Training Program units of eight universities in different parts of the United States and in a ninth group comprising the members of Army Specialized Training Program units of five New York medical and dental colleges. Approximately 12,500 men were involved. Each company or organization within a unit was divided in half, so that alternate individuals received, respectively, vaccine and control material. The commission stated in its preliminary report that vaccination done shortly before or even after the onset of the epidemic was found to exert a protective effect with a total attack rate of 2.22 per cent among the 6,263 vaccinated and 7.11 per cent among the 6,211 controls, a ratio of 1 to 3.2. The influence of vaccine was most clearly evident at the height of the epidemic prevalences.

In a subsequent communication Thomas Francis Jr.,² director of the commission, gives a more detailed analysis of the evidence obtained. Correlation of the individual reports from the various units demonstrates for the first time, according to Francis, that subcutaneous vaccine of the human population with inactivated influenza virus vaccine exerts a pronounced effect on susceptibility to influenza A during an epidemic of

high incidence. Rickard and his associates³ at the University of Minnesota found the clinical attack rate during an epidemic of influenza which began eleven days after vaccination to be 2.7 per cent, as compared to 9.06 per cent in the control group. The epidemic was proved to be due to influenza A by virus isolation, by positive serologic response or by both in a high percentage of clinical cases. The antibody response to influenza A virus produced by the vaccine was pronounced and similar to that caused by natural infection. Hale and McKee⁴ report from the University of Iowa that one subcutaneous inoculation with the influenza vaccine used in this area at the beginning of the epidemic effectively decreased the incidence of the disease in the vaccinated group.

In contrast to these are the observations of Eaton and Meiklejohn⁵ on their experiences with vaccine in California. They found that the gross incidence of febrile respiratory disease during the outbreak of influenza A was not appreciably different in a group of 796 vaccinated students from that in a group of 773 controls. In serologic tests by the Hirst chicken erythrocyte agglutination method, 19 of 63 patients with influenza A showed an insignificant rise in titer (twofold or less) with the strain PR8, while only 1 failed to show a fourfold increase in the same test with one of the current infecting strains. The effects of antigenic variations in the infecting strains of virus, of differences between the two vaccine preparations used, of the interval vaccination and infection and of other factors are considered as possible causes for the inferior results of vaccination in California as compared with those of other investigators using the same vaccines. Hirst and his associates⁶ report their experiences with vaccine at Princeton and Rutgers universities and the College of the City of New York. An epidemic of influenza A was investigated in the three populations. The epidemic was of mild character and affected about 8 per cent of untreated persons. The attack rate of the disease was 77 per cent lower among vaccinated than among control individuals, and demonstrable immunity first appeared on the eighth day after vaccination. Salk and his associates⁷ at the University of Michigan found an incidence of 8.58 per cent of cases hospitalized for influenza among 875 control cases and an incidence of 2.27 per cent among 878 vaccinated persons; thus 3.7 times as many cases developed in controls as among vaccinated individuals. Antibody

studies on serums obtained from a sampling of the control group before and after the epidemic revealed serologic evidence of influenza A infection in 41 per cent. These authors believe that dilution of the controls with an equal number of vaccinated persons in the study population may have reduced the incidence of disease among the controls and that a comparison of attack rates in completely vaccinated groups, if all other conditions were equal, would demonstrate a greater effect of vaccination than was apparent in this study. The observation that the differences in incidence between control and vaccinated subjects were greatest at the height of the epidemic and diminished as the epidemic progressed is interpreted to mean that the difference in concentration of susceptible persons was most pronounced at the onset and peak of the influenza prevalence. As the epidemic advanced by the natural immunizing procedure the concentration of susceptible persons in both control and vaccinated groups tended to approach the same level.

A striking relationship was observed between the level of serum antibody and frequency and severity of illness, in both control and vaccinated groups, when titers for the Weiss strain of type A virus were analyzed, while the trend was only suggestive in terms of the titers for the PR8 strain. The Weiss strain, isolated six months prior to the onset of the epidemic, appears to have been closely related antigenically to the strain prevalent during the outbreak in this area. The data indicate the existence of an antibody zone above which titers may have to be raised to produce the desired effect.

Current Comment

STREPTOMYCIN AND PROMIN IN EXPERIMENTAL TUBERCULOSIS

Guinea pigs infected with tuberculosis were employed by Smith and McClosky¹ to determine whether streptomycin has any beneficial effect, to compare the results of streptomycin therapy with the sulfone promin and to explore the possibilities of combined treatment with these two chemotherapeutic agents. Under the experimental conditions of treatment streptomycin injected intramuscularly produced a definitely greater chemotherapeutic effect than promin. The dose of promin used was about one half the maximum tolerated dose, while the dose of streptomycin used was less than one twentieth of its maximum tolerated dose; hence streptomycin had a therapeutic index at least ten times that of promin. Neither of these agents used alone completely eradicated the tuberculous process. Larger doses and better methods of administration may well increase the therapeutic effect of streptomycin. By the application of a suitable combination of promin and streptomycin, Smith and McClosky obtained results better than any

they had ever achieved before in the treatment of experimental tuberculosis infections. They believe their experimental results warrant the cautious application of combined treatment to selected patients.

PUBLICITY FOR SCIENTIFIC MEDICINE

Publicity for new discoveries in the field of medicine is a two edged sword. It may extend the hopes of the public far beyond what is warranted. It may cause pressure on physicians to try methods of treatment that may not be desirable. On the other hand, the public is certainly entitled to know about new discoveries in medicine and their significance in relation to the maintenance of health and the prevention of disease. Recently the periodical *Nordisk Medicin* has developed a special technic in relation to the scientific medical articles that it publishes with a view to solving this problem. When an article is undesirable or unready for public exploitation, the editors place at the top of the article as published in the medical journal the phrase "Ömtale i dagpressen förbjudes." This means that reproduction in the daily press is forbidden. Since the material in the publication is covered by controls, as our periodicals are covered by copyright law, this would seem to serve the purpose of delaying publicity for scientific contributions until the medical profession itself considers such publicity warranted.

METABOLIC FUNCTION OF PYRIDOXAL

Pyridoxal,¹ the δ -aldehyde of pyridoxine (vitamin B₆), apparently plays an important part in certain biochemical reactions. Gale and Epp² demonstrate in the case of bacterial decarboxylases that the enzymes decarboxylating the amino acids L-lysine, L-tyrosine and L-arginine are composed of two portions, a coenzyme-lase and a protein apocoenzyme-lase. Both portions must be present to promote enzyme action. All of the enzymes appear to have a common coenzyme-lase which has been obtained from yeast. Pyridoxal when added to the dried bacterial cells alone is inactive, but, if adenosine triphosphate is added, decarboxylation of amino acids occurs; the function of the adenosine triphosphate is to phosphorylate the pyridoxal, forming pyridoxal phosphate. Recently Baddiley and Gale³ phosphorylated pyridoxal chemically; when it was added to the apocoenzyme-lase, full enzymatic activity for the decarboxylation of either tyrosine, arginine, lysine or ornithine was regenerated. Until pure compounds are isolated it cannot be proved that the coenzyme produced from pyridoxal through activation with yeast juice is identical with that obtained by strictly chemical activation. Nevertheless the foregoing observations offer considerable evidence regarding the function of pyridoxal in bacteria. The research here reported is a fine example of the manner in which fundamental knowledge of the nature of bacteria is being acquired that may lead eventually to new techniques for control.

MEDICINE AND THE WAR

ARMY

ATYPICAL LICHEN PLANUS AMONG PACIFIC TROOPS

The Office of the Surgeon General recently revealed that army doctors in the Southwest Pacific have found fewer than 3 cases per thousand men of a new noncontagious skin disease, which has been named atypical lichen planus and is known to the soldier as one of the varieties of "jungle rot."

Atypical lichen planus apparently becomes active partly because of an occasional unusual sensitivity of a few individuals to atabrine, the drug which was used so successfully in combating malaria among troops in the tropics, army medical reports indicate. However, army doctors emphasize that the vast majority of persons who take atabrine regularly are not affected.

First reports describing this disease were submitted by two army dermatologists in the Southwest Pacific: Lieut. Col. Charles Schmitt of Pittsburgh and Major Thomas Nisbet of Pasadena, Calif. Their studies convinced them that atabrine was the underlying cause. Although medical officers agree with this opinion, they also recognize that many factors are probably contributory. These include skin injuries and irritations of many kinds, excessive exposure to sunlight, profuse perspiration, dietary deficiencies, and emotional and nervous factors. Older men have been found to be more susceptible than younger men, and the disease has also occurred among nurses and Wacs.

Studies revealed that the few men and women who did contract the disease did so after atabrine had been taken only for several months, not regularly over a prolonged period.

Medical officers soon learned to recognize atypical lichen planus in its early stages and were able to prevent its spread to other parts of the body. In all but a small percentage of cases the disease has cleared up under treatment.

PRODUCE FOURTEEN OUNCES OF STREPTOMYCIN A MONTH

The War Department recently stated that streptomycin, a new wonder sister drug to penicillin, was being used in thirty army general hospitals over the country but that it was so difficult to obtain that the total output of the four companies now making it has been only 14 ounces a month.

Major Gen. Norman T. Kirk, Surgeon General of the Army, said that the Army was receiving many requests for the drug for use in treatment of urinary and other infections caused by gram negative bacteria which do not respond to penicillin but that these cannot be met since the Army neither controls the supply nor can get enough for its own needs in treatment of soldiers wounded in battle. "The Army and Navy are purchasing only a part of available production," General Kirk said. "In August, 28 ounces or 800,000,000 units was purchased. Joint Army-Navy expectations for September are 162 ounces, but it is anticipated that production will be not more than 70 ounces. It is hoped that Army-Navy procurement can be doubled in October for military needs alone now are about 2,000 ounces a month."

General Kirk stated that Merck, Upjohn, Abbott and Squibb were the principal manufacturers of the new product but that other concerns were working at experimental production at pilot plants and that any civilian request for streptomycin naturally would go to these companies.

MERITORIOUS SERVICE PLAQUE

The 45th General Hospital was recently awarded the Meritorious Service Unit Plaque for superior performance of duty in the accomplishment of exceptionally difficult tasks in the Peninsular Base Section for the period June 1, 1944 to Dec. 1, 1944.

AVIATION MEDICAL EXAMINERS GRADUATE

One hundred and forty-five medical officers recently completed the Aviation Medical Examiners' course at the Army Air Forces School of Aviation Medicine, Randolph Field, Texas. Lieut. Col. Fratis L. Duff, assistant commandant of the school, presented awards to 145 flight surgeons and 20 flight nurses.

CLINICAL PSYCHOLOGIC SERVICES

Because of the close relationship between psychiatry and clinical psychology, the Office of the Chief, Clinical Psychology, Classification and Replacement Branch, Adjutant General's Office, has been recently transferred to the Office of the Surgeon General. Col. Morton A. Seidenfeld has been assigned as chief, Clinical Psychology Branch, Division of Neuropsychiatric Consultants, and Capt. L. I. O'Kelly has been designated assistant chief of the Clinical Psychology Branch.

Provision has also been made for the detail of all clinical psychologists now serving as officers into the Medical Administrative Corps. This step will permit an increase in the effectiveness of their utilization in medical installations where they will be under the direct control of the Medical Department.

ARMY HOSPITAL UNIT COMMENDED

The 20th General Hospital was recently commended the citation being addressed to Lieut. Gen. Dan. I. Sultan, U. S. Forces, India-Burma theater: "Under extremely difficult climatic conditions and in an area devoid of practically everything usually considered necessary for the construction and operation of a general hospital, you have built an institution that has been complimented by every one who has visited it. The record of the 20th General Hospital would be outstanding in any theater of operations. Much of this achievement can be attributed to your fine qualities of leadership, but your officers, including your nurses, and all of your men have shown a devotion to duty which is worthy of the highest praise."

165TH STATION HOSPITAL COMMENDED

The 165th Station Hospital, under the command of Col. G. I. Sneiderman, was recently commended "for its superior performance and outstanding devotion to duty during operations against the enemy from Dec. 26, 1944 to June 30, 1945. The untiring effort and high degree of professional skill evidenced by all officers and enlisted men have contributed materially to the alleviation of suffering of the wounded and the survival of many who were critically wounded. The inspiring manner in which the 165th Station Hospital has carried out its mission reflects great credit on the Medical Department and the military service as a whole."

OLD FARMS CONVALESCENT HOSPITAL CITED

The Old Farms Convalescent Hospital (Special) at Avon, Conn., was recently awarded the Meritorious Service Unit Plaque for its work with the blinded soldiers. In making the award Major Gen. Norman T. Kirk, Surgeon General of the Army, said "The Old Farms Convalescent Hospital (Special), first established in June 1944, quickly developed into an institution unique in its kind in the country, even in the world. Able administered, the institution has taken over the important problem of social adjustment of the blinded soldier and in these relatively few months has succeeded in its purpose admirably."

ARMY AWARDS AND COMMENDATIONS

Major Clement E. Steyer

Major Clement E. Steyer, formerly of Cleveland, was recently awarded the Bronze Star for achievement in support of combat operations while on duty on the Army Hospital Ship *Emily H. M. Weder* from August 1944 to March 1945. The citation accompanying the award explained that "during the invasion of southern France, in the Italian combat zone and later in the landings on Leyte and Luzon in the Philippines this hospital ship participated in the evacuation of wounded from the established beachheads. Under difficult working conditions and in perilous water he personally supervised the screening of arriving casualties aboard ship and organized shock teams for immediate medical therapy. Complementing his medical administrations with a refreshing sense of humor and a calm manner, he consistently placed evacuated patients in a far healthier frame of mind and gave them confidence. His achievements contributed greatly to the recovery, both physical and mental, of many casualties and reflected great credit on the medical service." Dr. Steyer graduated from St. Louis University School of Medicine in 1924 and entered the service Oct. 19, 1942.

Captain Gustavo A. Motta

The Bronze Star Medal was recently awarded to Capt. Gustavo A. Motta, formerly of Providence, R. I., for "meritorious service in connection with military operations against an enemy of the United States in eastern France and Germany from March 1, 1945 to April 24, 1945. During the division's offensive operations against the enemy in eastern France and Germany between March 1 and April 24, 1945, Captain Motta, as battalion surgeon, performed his duties in an outstanding manner. Despite the necessity of working long hours and under adverse conditions, oftentimes under enemy fire, he displayed superior knowledge and unusual professional ability in the care and treatment of our sick and wounded. His medical skill and untiring efforts contributed substantially to the maintenance of a high standard of medical treatment within the battalion. His outstanding professional ability and selfless devotion to duty and the wounded reflect the highest credit on Captain Motta and on the armed forces of the United States." Dr. Motta graduated from Georgetown University School of Medicine, Washington, D. C., in 1940 and entered the service Feb. 25, 1944.

Captain Spencer Myers

Capt. Spencer Myers, formerly of Ossining, N. Y., was recently awarded the Bronze Star in recognition of his meritorious performance of duty in connection with military operations against the enemy near Luzon in the Philippines. The citation read, in part, "He not only worked as a battalion surgeon in an efficient and untiring manner but was also outstanding in rendering medical attention to two enlisted men who had been wounded by fragments of a knee mortar." Dr. Myers graduated from New York University College of Medicine, New York, in 1932 and entered the service Aug. 15, 1942.

Major Thomas N. Horan

The Bronze Star was recently awarded to Major Thomas N. Horan, formerly of Detroit, "for meritorious achievement in support of military operations." He is chief of officers' section in the 17th General Hospital (U. S.), a unit which was presented with the Meritorious Service Unit Plaque for superior performance of duty in connection with furnishing medical service to the Fifth Army and other U. S. Troops in the Mediterranean Theater of Operations. Dr. Horan graduated from the University of Michigan Medical School, Ann Arbor, in 1926 and entered the service July 15, 1942.

Lieutenant Colonel Alfred Campbell Ledoux

Lieut. Col. Alfred Campbell Ledoux, formerly of Evanston, Ill., was recently awarded the Bronze Star. The citation read, in part, "Lieut. Col. Alfred Campbell Ledoux, while serving in the Army of the United States, distinguished himself by

meritorious service in connection with military operations not involving aerial fight against an enemy of the United States. As chief of the x-ray service, 108th General Hospital, Lieutenant Colonel Ledoux was instrumental in the discovery, the reconstitution of and the early adaption of captured German x-ray and radiotherapy equipment. This was accomplished by virtue of his initiative, specialized technical knowledge and highly professional attainments. The immediate availability of this splendid equipment at a time when transport of our own equipment was extremely difficult and uncertain, owing to the exigencies of the military situation, materially assisted in the diagnostic care and treatment of many thousands of casualties." Dr. Ledoux graduated from Tufts College Medical School, Boston, in 1929 and entered the service Jan. 1, 1943.

Major Robert K. Whitely

The Bronze Star was recently awarded to Major Robert K. Whitely, formerly of Detroit, who, while a prisoner of war in Japanese Prison Camp No. 1, Cabanatuan, Philippine Islands, from October 1944 to January 1945, performed conspicuous service as ward surgeon in a general hospital. The citation called attention to the fact that "with improvised, makeshift equipment and depleted medical supplies, he labored against great odds and on a starvation diet. In addition to his medical tasks he assumed the very difficult assignment of provost marshal of the prison camp. He was responsible for interpreting Japanese regulations and orders and having them carried out in every detail. He also maintained order in camp and administered appropriate disciplinary measures when necessary. His outstanding performance under extremely difficult and hazardous conditions contributed in great measure to the well-being of his fellow prisoners of war." Dr. Whitely graduated from the University of Michigan Medical School in 1933 and entered the service Nov. 5, 1940.

Colonel Ernest H. Parsons

Col. Ernest H. Parsons, commanding officer of the 108th General Hospital, Paris, France, was recently awarded the Legion of Merit for conspicuous service during the Battle of the Bulge last December. At the time of the von Rundstedt breakthrough near Liège, Belgium, Colonel Parsons was commanding officer of the 130th General Hospital. On Christmas eve the Americans were compelled to withdraw and leave the seriously wounded in the hospital. Although he could have appointed any of his officers to remain, Colonel Parsons, with two junior medical officers and twenty-five enlisted men, stayed in the hospital to care for the wounded. The Germans occupied the position and advanced beyond it. For three days, over the Christmas holiday, Colonel Parsons and his cadre worked behind the German lines. Dr. Parsons graduated from Vanderbilt University School of Medicine, Memphis, in 1930 and entered the service June 11, 1930.

Colonel Henry R. Carstens

The Legion of Merit was recently awarded to Col. Henry R. Carstens, formerly of Detroit, "for exceptionally meritorious conduct in the performance of outstanding services." Dr. Carstens is the commanding officer of the 17th General Hospital (U. S.), a unit which received the Meritorious Service Unit Plaque for superior performance of duty while furnishing medical service to the Fifth Army and other U. S. troops in the Mediterranean Theater of Operations. He graduated from Wayne University College of Medicine, Detroit, in 1911 and entered the service July 15, 1942.

Captain A. Ebner Blatt

The Bronze Star was recently awarded to Capt. A. Ebner Blatt, formerly of Indianapolis. The citation stated that Captain Blatt "distinguished himself by heroic achievement in connection with military operations against the enemy. His coolness in face of danger and his complete disregard for his personal safety while evacuating wounded under enemy fire were in accordance with highest standards of military service." Dr. Blatt graduated from Indiana University School of Medicine, Indianapolis, in 1934 and entered the service Oct. 29, 1942.

Colonel Charles M. Downs

Col. Charles M. Downs, formerly of Indianapolis, was recently awarded the Bronze Star for meritorious achievement in connection with military operations. The citation states that "during the period of September 30 to October 20 Colonel Downs as surgeon of X Corps planned the movement for and the execution of the successful landing of X Corps medical units on the island of Leyte. During the operations from October 20 to December 20 he coordinated the activities of all medical units under X Corps control, attaining maximum effort. His leadership, superior knowledge, medical ability and untiring efforts contributed greatly to the saving of many lives through

speedy evacuation and effective medical aid." Dr. Downs graduated from Indiana University School of Medicine, Indianapolis, in 1927 and entered the service Aug. 3, 1928.

Major Harold C. Adkins

Major Harold C. Adkins, formerly of Indianapolis, was recently awarded the Presidential Citation for his work during the Normandy invasion. He has been a participant in five major battles, including the invasion of Italy, both invasions of France, the Netherlands and Bastogne. Dr. Adkins graduated from Indiana University School of Medicine, Indianapolis, in 1928 and entered the service April 6, 1942.

MISCELLANEOUS

EPIDEMIOLOGICAL INFORMATION BULLETIN NO. 15

The Epidemiological Information Bulletin No. 15, recently released by the United Nations Relief and Rehabilitation Administration, states that tuberculosis and syphilis are the two most important health problems of liberated Manila.

Based on returns for the first three months of liberation, the death rate for pulmonary tuberculosis for a year has been calculated at 800 per hundred thousand inhabitants, or about twenty times that of the average American city. In ten weeks 2,045 new syphilis cases were found among the civilian population, and the incidence continues to increase. Gonorrhea is equally prevalent. Manila was one of the few cities of tropical Asia where malaria had been reduced to a low level. During the Japanese occupation the disease returned, and it now constitutes a serious problem. There has been no significant increase of other epidemic diseases.

War shattered cities in continental Europe are also suffering from serious epidemics. The mortality from pulmonary tuberculosis has more than doubled in Rome. Epidemics of bacillary dysentery of a severe type and of typhoid are spreading in Berlin, where diphtheria too is once more on the increase. There were 1,100 cases of typhoid during the first three weeks of August. At Helsinki, Finland, there have been 2,472 paratyphoid fever cases up to September 6. Diphtheria remains widespread in the Netherlands, where half of the cases now occur among adults.

The Epidemiological Information Bulletin is issued bimonthly by UNRRA in pursuance of responsibility delegated by the International Sanitary Conventions of 1944 for gathering and publishing official information regarding the incidence of epidemic diseases throughout the world.

UNRRA HEALTH PROGRAM IN CHINA

Dr. Leland A. Powers, former Health Director of the state of Washington and now chief medical officer for the United Nations Relief and Rehabilitation Administration in Chungking, recently reported the activities of the health program in China. Eighteen doctors, sanitary experts and nurses joined the staff in Chungking, a special training program for Chinese experts was completed, a serious cholera epidemic brought under control and action started on requests for speedy recruitment of approximately 200 additional medical persons for field operations.

Dr. Powers is developing the work of the UNRRA health division in cooperation with Dr. Chang Wei, chief medical officer of the Chinese National Relief and Rehabilitation Administration (CNRRA), and Dr. P. Z. King of the Chinese National Health Institute. A medical teaching project to instruct Chinese medical and public health personnel in the necessary technics for relief work got under way in the early summer.

To date over 100,000 pounds of medical supplies has been sent into China for use in the medical programs. The bulk of these vital supplies were shipped while China was still under Japanese occupation, and difficulties of closed ports and roads were cir-

cumvented by shipping the supplies to India and flying them from there "over the hump" of the Himalayas.

As the field work continues to extend into the devastated areas left by the retreating Japs, more medical teachers—general practitioners, nurses, bacteriologists and specialists of every description—are needed and are being recruited to help China launch her extensive medical relief program. It has been roughly estimated that in the next four years China will have to train 35,000 technicians to do the job. UNRRA is attempting to fill present requests from China for 200 medical field workers and has set a recruitment goal of 100 medical men and 30 nurses by the end of this year.

WARTIME GRADUATE MEDICAL MEETINGS

The following subjects and speakers for Wartime Graduate Medical Meetings have just been announced:

California

Birmingham General Hospital, Van Nuys: Surgery of the Biliary Tract, Capt. Howard K. Gray, November 14; Thoracic Surgery, Capt. W. L. Rogers, November 28.

U. S. Regional Hospital, Pasadena: Thyroid Disease, Lieut. Comdr. George Crile, November 12.

A. A. F. Regional Station Hospital, March Field: Compound Fractures, Comdr. P. E. McMaster, November 20.

U. S. Naval Hospital, Long Beach: Liver Disease Capt. John Ruddock, November 21.

Station Hospital, Camp Stoneman, Pittsburg: Plastic Surgery, Dr. George Pierce, November 17.

Hammond General Hospital, Modesto: The Use of Penicillin in Injuries and Infections, Dr. Horace J. McCorkle, November 21.

A. S. F. Regional Hospital, Oakland: Diagnosis and Management of the Lymphomas, Dr. Ernest H. Falconer, November 14.

Station Hospital, Fort Ord: Diseases of the Thyroid: Clinical Diagnosis and Management, Dr. Mayo H. Soley, November 17.

U. S. Naval Hospital Treasure Island: Interpretation and Misinterpretation of Certain Laboratory Tests, Dr. James Hopper, November 16.

Pennsylvania

U. S. Naval Hospital, Philadelphia: Clinical Significance of Diplopia, Dr. Walter I. Lillie, November 16.

QUARANTINE RESTRICTIONS WIDENED ON AIR TRAVEL

Under the jurisdiction of the International Sanitary Convention, quarantine restrictions on air travel were placed on several hundred additional square miles in Brazil and the Barotze province in northern Rhodesia. The restrictions became effective with the acceptance recently by the Standing Technical Committee on Health of a report of the Expert Commission on Quarantine redefining endemic yellow fever areas. The committee, which held its ninth regular meeting September 26 at UNRRA headquarters, also approved the progress report of the Health Division.

ORGANIZATION SECTION

REPORTS OF OFFICERS

NOTE.—At the 1925 session of the Association, the House of Delegates suggested that all reports of officers, committees, etc., and resolutions to be brought before the House, if available, be published in advance of the session so as to permit careful consideration and discussion. The Report of the Secretary, additional sections of the Report of the Board of Trustees and reports of some councils, bureaus and departments will appear in subsequent issues of The Journal.—Ed.

(Continued from page 561)

REPORT OF THE COUNCIL ON MEDICAL SERVICE AND PUBLIC RELATIONS

To the Members of the House of Delegates of the American Medical Association

Immediately after the final session of the House of Delegates in June 1944 the Council on Medical Service and Public Relations met to organize

Dr. John H. Fitzgibbon was elected chairman, Dr. E. J. McCormick vice chairman, and an executive committee was appointed consisting of the chairman, Dr. Fitzgibbon, the Trustee member, Dr. L. H. Bauer, and Dr. Alfred W. Adson. Following the resignation of Dr. Fitzgibbon as chairman, Dr. McCormick was elected chairman and Dr. James R. McVay vice chairman and member of the executive committee of the Council at its June 1945 meeting. The Washington office of the Council was established Sept. 1, 1944.

RELATIONS WITH OTHER DEPARTMENTS

It was felt that the first task of the Council should be to clarify its relations with the other Councils and Bureaus of the Association. Consequently a statement was drawn up covering this matter and submitted to the Board of Trustees the day following adjournment of the House of Delegates. The Board approved this statement, which follows:

Under the duties of the Council as laid down in the By Laws there are six definite fields which are somewhat interlocking:

1 To make available facts, data and medical opinions with respect to timely and adequate rendition of medical care to the American people.

This will require the services of the Bureau of Medical Economics in assembling statistical material in making surveys and in preparing analyses of medical care plans for the Council's study. It will require the services of the Bureau of Legal Medicine and Legislation in preparing factual analyses of any legislative angles and it will require the services of the Department of Public Relations in spreading the information through the publications of the American Medical Association. The Council may also effect distribution of some of the information through its bulletins.

2 To inform constituent associations and component societies of proposed changes affecting medical care in the nation.

This, of course, concerns legislation. It should be one of the functions of the Washington office. The information assembled by the Washington office, and other sources of information, should be transmitted to the states and by them to the counties unless the states have requested that the counties be notified direct. Under the plan proposed by the Council and approved by the representatives of those states sending representatives to conferences already held, there should preferably be one man designated by the state who will serve as the contact agent of that state with the Washington office. The information should be sent to the contact agent whose duty it will be to distribute this information as directed by his own state. In cases in which the proposed bill alone is to be sent, it may be sent direct from the Washington office, with copies going to the Council office in Chicago and to the other association bureaus and departments concerned in the Chicago headquarters with request for advice from the department concerned. In case a factual analysis is to be made, this will be done in collaboration by the Washington director and the Director of the Bureau of Legal Medicine and Legislation, by mail when time permits and when it does not by telephone. The same will apply when the implications of the bill are to be included.

3 To inform constituent associations and component societies regarding the activities of the Council.

This will be done by means of the Council's bulletins and with the cooperation of the Department of Public Relations by means of the Association's publications.

4 To investigate matters pertaining to the economic, social and similar aspects of medical care for all the people.

This will involve both the methods covered in 1 and 2 as there will be required both economic investigations by the Bureau of Medical Eco-

nomics and the legislative aspects of the matter concerned by the Bureau of Legal Medicine and Legislation. The information received from the Bureau of Medical Economics from the Washington office and a legislative analysis of the same by the Bureau of Legal Medicine and Legislation would be compiled in the Chicago office for submission to the Council for its study.

5 To study and suggest means for the distribution of medical service to the public consistent with the principles adopted by the House of Delegates.

Based on the results of the first four activities, the Council will prepare its recommendations for the approval of the Board of Trustees or, in case new principles are involved, for submission to the next session of the House of Delegates.

6 To develop and assist committees on medical service and public relations originating within the constituent associations and component societies of the American Medical Association.

To do this a field agent is necessary. Many of the representatives attending the conferences on June 11 and the meeting of the House of Delegates expressed their desire for an arrangement whereby conferences could be held with state representatives. It was also recommended in the Supplementary Report of the Council. The idea of the Council is that this field agent should spend some time in Chicago familiarizing himself with all the activities of the Council and should keep in frequent touch with the Chicago office thereafter. However, he should act as a direct contact between the Washington office and the state agents mentioned. Under the direction of the Washington director and with the approval of the Council, invitations would be issued to groups of states to attend conferences in central areas. The states would be asked to send their contact agents and such others as they see fit to these conferences. The states would be asked to effect an organization within the state so that quick action could be had in emergencies in bringing to the attention of members of Congress the attitude of the medical profession on certain bills. The contact with the congressmen would be by these local units. The field agent would outline the plan to them and offer such assistance as the states desired. Contacts could be kept up then by correspondence with the state agents and only occasional personal contacts thereafter.

The Washington director would be responsible for obtaining information on legislative or government departmental matters and transmitting it to the proper persons as outlined. He would have available all information possible on Association activities for the benefit of Congress and the government departments. He would see to it that both were informed that such a source of information was available for their use when desired. He would discuss bills with members of Congress when requested to do so by them or furnish them such information as requested by the congressman's constituents. He would never exert any pressure on any member of Congress in an effort to influence his vote.

The director would develop sources of information gradually, and the Department of Public Relations would furnish him promptly with all information of a legislative nature which comes to it. The director would likewise keep the Department of Public Relations informed.

A part time legal counsel was recommended in the Council's Supplementary Report. The purpose of this counsel would be to give advice on the meaning of legal phraseology of bills and their legal implications, and the relationship of this bill to other legislation. For the present, at least, it would appear that this could be done by the Bureau of Legal Medicine and Legislation although, in emergencies, some one on the ground would be essential.

There should also be a secretary to the director who should be a college graduate with secretarial training. A stenographer would also be necessary.

The director would function under the supervision of the Council or its executive committee.

SECRETARY

As Dr. G. Lombard Kelly's resignation took effect on July 1, 1944, the Council was without a secretary. Mr. J. W. Holloway, Jr. was designated as acting secretary, which position he filled to the great satisfaction of the Council, although the work of the Council was seriously handicapped since Mr. Holloway, because of other duties, could devote only part of his time to the Council. In February 1945 arrangements were made with the Indiana State Medical Association for the loan of Mr. Thomas A. Hendricks on a part time basis.

BULLETINS, NEWS LETTER AND COUNCIL RELEASES

During the last few months three types of bulletins have been released under the direction of the Council:

News Letter.—The News Letter is sent to about 2,200 physicians who are state medical society officers and members of local public relations committees, to the members of the House of Delegates and to the officers of the American Medical Association. These letters are designed to serve the busy doctor as a periodic "briefing" on developments on the medical economic and political front.

Bulletins on Special Subjects.—Special bulletins covering events and reports on subjects not officially dealt with by other bureaus and councils are released by the Council on Medical Service and Public Relations. An example of such bulletins was the release giving a summarized report, with comments on the Fourth Interim Report of the Subcommittee on Labor and Education covering "Health of the Veteran." These bulletins go to 229 state medical society officers and are valuable in supplementing the information which appears in the Organization Section of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Bulletins from Washington Office.—These bulletins are discussed in the report on the Washington Office by Dr. Joseph S. Lawrence, which is a part of this report.

Public Relations Kits.—These kits, which will be supplied to each delegate, will contain:

1. The fourteen point Program of the American Medical Association.
2. Objectives of the Council.
3. Articles that have appeared in THE JOURNAL on regional conferences.
4. Copies of the News Letter and Special Bulletins.
5. Bulletins from the Washington Office.
6. Legislative Résumé by the Bureau of Legal Medicine and Legislation.

Speakers' Kits.—The Council intends to supply as soon as possible "speakers' kits" to all who may be called on to give talks to medical societies or lay groups. Each kit will supply basic material that may be augmented and applied to local conditions as the circumstances warrant.

INSURANCE

One of the mandates of the House of Delegates was that the Council should employ a full time Director of Insurance. The Council feels that the field of voluntary insurance is one which perhaps is the most important of all for its activities at this time. Although the Council has striven to obtain the services of a qualified man, so far its efforts have been unavailing; but it hopes that the proper person will be obtained before the House meets again.

The immediate problems in this field are:

1. Bringing up to date the information on the various medical society indemnity and service plans.
2. Study of how they may be improved and extended.
3. Methods of stimulating the formation of new plans.
4. A study to bring up to date information on various industrial plans.
5. A study of commercial plans.
6. A study of the feasibility of a national plan.

The problem of voluntary sickness insurance has received much attention from the Council. With the cooperation of the directors of the various plans sponsored by county and state medical societies, a study is being made on this subject. A preliminary report on this survey appeared in the Aug. 18, 1945 issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION and other reports will follow from time to time. Several proposed plans for the formation of a national indemnity company have been submitted to the Council. In general these plans each proposed the formation of a company based on the Blue Cross organizations to sell indemnity insurance to employers having national payrolls and to utilize the facilities of local plans wherever they were available and to stimulate the formation of other such plans where none existed, the national company to withdraw from the field of competition wherever such existed. Sponsors of these plans claimed that, as far as medical policies and services are concerned, these were to be in the hands of the medical profession.

While in essence this was the proposal in each plan, there was no written confirmation of some of the points in any plans proposed, and, as these plans were indefinite in many of their

points, the Council felt that it could not approve them. The Council did, however, relay to the sponsors of one plan, certain basic fundamentals which it felt would be necessary before any plan could hope to obtain the support of the medical profession. These fundamental points were that:

1. Any plan developed must deliver medical control of all medical policies and medical service into the hands of the medical profession.
2. The final approval of the selection of any medical control board set up under 1 should in the last analysis be by a responsible group of the organized medical profession.
3. The plan must not interfere with the development of either cash indemnity or service plans developed by local medical societies.
4. The practice of hospitals selling medical service is not approved, and the special services of anesthesiology, pathology, radiology or physical therapy or any other medical service should be in the medical contract and not in the hospital contract.

The Council received a delegation representing large and important insurance companies on the matter of a fee schedule for surgical and maternity care. This delegation asked the help of the Council to evaluate the various surgical procedures in order to grade the various procedures on a unit scale. After thorough discussion it was decided to appoint a consulting committee of surgical specialists to consider the feasibility for assessment of the various surgical procedures in a unit system for purposes of insurance reimbursement.

A Conference on Medical Service Plans to include discussion on the following points was planned but had to be postponed because of the restrictions on transportation:

- Full Coverage vs. Limited Coverage.
- Service vs. Indemnity (Reimbursement) Plans.
- Actuarial Facts in Relation to Administrative Factors.
- Relation of Medical Care Plans to Hospitalization.
- Relation of Medical Societies to Administration of Medical Care Plans.
- Relation of Specialist to Insurance Plans.
- Interstate Coordination of Medical Care Plans.
- Relation of N. P. C. to Prepayment Plans.
- Indigent.
- Rural Enrolment.
- Individual Enrolment.
- Low Cost-Low Benefit Plan.
- Trade Territories vs. State Lines.
- Income level.
- Family Coverage.

INDUSTRIAL HEALTH

A joint meeting with the Council on Industrial Health was held Aug. 31, 1945. This would have been held earlier had not wartime restriction interfered. Details in regard to this meeting will be reported in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

CONTACTS WITH OTHER GROUPS

At the December 1944 meeting of the Council, conferences were held with representatives of the American Federation of Labor and with representatives of the various government agencies in Washington.

Two releases were drawn up and given to the press, both of which dealt with means of making the Platform of the American Medical Association an active program. Both of these releases were sent to the Council's mailing list.

Discussion was also had as to the advisability of legislation to further the aims of this program, and the Council's recommendation was referred to the Board of Trustees.

The Council has arranged a meeting to be held Oct. 18, 1945 in Chicago with representatives from the special obstetric, pediatric, orthopedic, heart and general practitioner groups to discuss the EMIC program.

SERVICE FELLOWSHIPS

The Council is very much disturbed over the fact that many Fellows of the American Medical Association have lost their fellowships while in the military service. While no one loses his membership so long as he remains in good standing in his county and state societies, which in most instances have remitted the dues of members in service, many have lost their Fellowship in the American Medical Association. As a result of this many men in service have not received the selected Association's publications. The Council, therefore, recommends that the necessary changes in the By-Laws be prepared for submission to the House of Delegates to provide that any Fellow entering the armed forces retain his Fellowship, and that all those who have been dropped as Fellows be reinstated and kept on the

list of Fellows until the end of the war or six months after the termination of their military service. Such Fellows, of course, would not be entitled to receive any of the journals unless they subscribed but their status as Fellows would be protected.

CHRONIC DISEASE, INCLUDING CANCER

The Council recommended that a committee on chronic diseases be set up by the Board of Trustees, as that particular field does not seem to fall within the province of any existing council or committee of the American Medical Association.

The executive director of the American Cancer Society appeared before the Council and asked that the American Medical Association set up guiding standards for cancer clinics to be operated under the supervision of the county medical societies.

It was voted that the Council appoint an advisory committee to confer with the American Cancer Society until such time as the Board of Trustees appoints a committee on chronic diseases when it seems feasible that this latter committee should take over the work. The purpose of this advisory committee is to go into the objectives of the American Cancer Society and to draw up general standards for cancer clinics when and where such clinics are operated with the approval of county medical societies. The Council feels that each state society should have such advisory committees.

INTERIM AUTHORITY

The Council feels that authority should be given to some group to act on questions of public policy in the interim between meetings of the House of Delegates. While the House of Delegates is the policy making body of the Association, and rightly so, nevertheless, emergencies arise which should be met promptly, and the delay of awaiting a decision of the House might prove disastrous. Hence the Council recommends that either the Board of Trustees or the Executive Committee of the Board and the executive committee of the Council, acting jointly, be given authority to determine the stand of and initiate appropriate action for the American Medical Association when urgent questions arise.

LEGISLATION

The Council has also considered many legislative matters, especially the Hill (Colorado)-Burton (Ohio) bill (S. 191), the Ellender (Louisiana) bill (S. 637), the Wagner (New York)-Murray (Montana)-Dingell (Michigan) bills (S. 1050 and H. R. 3293) and the Pepper (Florida) bill (S. 1318) to extend the EMIC program.

WASHINGTON OFFICE

Report of Washington Office by Dr. Joseph S. Lawrence, Director:

The Washington Office of the Council on Medical Service and Public Relations, located on the ninth floor of Doctors' Hospital, 1835 I Street N.W., was formally opened on Sept. 1, 1944. Considerable difficulty was experienced in obtaining priorities for both personnel and equipment. However, eventually the necessary authority was obtained and, while the office space, equipment and staff are still far from adequate, they are the best that can be obtained at present.

Bulletins.—At once steps were taken to establish relationships with the state associations. The officers of each association were asked to select persons in their associations with whom they expected the office to communicate. This list of names became the nucleus for a bulletin and mailing list.

Hearings.—Early in September two congressional committees were holding important hearings, a subcommittee of the Senate Committee on Education and Labor was holding hearings on the general subject of wartime health and education; a committee of the House of Representatives, also a subcommittee of the House of Representatives Committee on Labor was holding hearings at which testimony was taken as to the economic situation of the physically handicapped. In September the field of the aid to the deaf and the hard of hearing was particularly explored. These hearings were attended and reported, abstracts being made from the statements handed in by the witnesses. These abstracts were distributed to those on our mailing list by a series of bulletins.

The bulletins were very well received and many requests were sent in for the addition of names to the mailing list. The list started with probably 300 names and at present there are approximately 700 names.

Report of Bills.—With the inauguration of the new Congress, the 79th, the office began to report through the mailing list the bills as they were introduced which have a bearing on health or medical practice. The bill is reported by number, the name of its introducer and the committee to which it is referred. If possible it is ascertained from the introducer his particular reason for asking for legislation of this character. A short statement is made of what the bill contains if the title is not too clear. Mr. Holloway, Director of the Bureau of Legal Medicine and Legislation, will analyze and interpret the bills and distribute that information through his mailing list. Notification will be made in the bulletins of any hearings that may be announced and the status of bills reported out of committee. To date twenty-nine House bills and eight Senate bills have been reported.

Congressman Arthur L. Miller (Nebraska), a physician, introduced early in the session of the 79th Congress a bill (H. R. 1391) providing for the assembling of the various health activities now distributed among more than a score of federal departments and bureaus into one department, the United States Public Health Service. He argues that such an arrangement would be both more efficient and economical than the present conditions. He also provided in the bill for the creation of a position in the President's cabinet for a Secretary of Health. The hearings conducted by the Subcommittee on Postwar Planning during the last summer and autumn were very informative and enlightening on the state of health and medical conditions in the nation. The principal finding is that conditions in the rural areas are definitely inferior to what can be expected in urban areas but at present the congestion of population in industrial areas, especially where defense plants are located, has produced a severe strain on health and medical facilities there also.

Testimony at these hearings was given by prominent leaders and authorities in health and medical societies, industry, labor, education, agriculture and social affairs. A common refrain from all was the discouraging ignorance of what is good health and the lack of interest on the part of many in achieving or maintaining it. There is an obvious need for a widespread health education program. Industrial leaders testified to the benefits derived from the institution of scientifically prepared and supervised nutritional opportunities in their factories. Educators told of the great advantages school children are reaping where the schools provide luncheons. The ignorance of the average individual of the facts of proper diet and living conditions is deplorable, they declared.

Outgrowths of these hearings and stimulated by them are a number of bills: (1) The Hill (Colorado)-Burton (Ohio) Hospital bill (S. 191), which would aid rural districts to procure needed hospital facilities, (2) Weiss (Pennsylvania) (H. R. 2044) and Hartley (New Jersey) (H. R. 2045) Physical Fitness bills and (3) several proposals to aid schools to provide th: children with supplementary luncheons.

It was also brought out at the hearings that the principal cause for classification as 4-F was illiteracy and, second, mental conditions unsuitable for combat war. About 16 per cent of those classified as 4-F could probably be cured or improved by suitable medical attention; but a startling observation was reported in this connection, namely that in a certain district disqualifying defects found by the Selective Service examining board had been discovered years before by school examining physicians and reported to the parents but never corrected.

Providing adequate medical care for the veterans is looming up as the major health and medical problem for the next few years. A number of bills are before Congress suggesting needed changes in the present laws. These bills should receive careful study by us: H. R. 650 Allen (Louisiana), H. R. 1513 Kildey (Texas), H. R. 1661 Rogers (Massachusetts), H. R. 2253 Priest (Tennessee), H. Res. 172, H. Res. 185 Rankin (Mississippi), H. R. 2611 Latham (New York) and H. R. 2920 Rogers (Massachusetts).

Another investigation in progress is the rehabilitation of the handicapped. Measures are being developed to help especially the blind and hard of hearing to adjust and adapt themselves so as to be self supporting. Among such bills are H. R. 141 Voorhis (California), H. R. 1411 Angell (Oregon), H. R. 1415 Angell (Oregon), H. R. 2020 Voorhis (California) and H. Res. 45 Kelley (Pennsylvania).

Grave concern was manifested over the decision of the Selective Service to discontinue deferring students who desire to enter the medical profession. Senator Ellender of Louisiana, having endeavored to have the Army reconsider its action without avail, introduced a bill (S. 637) hoping to secure the approval of Congress. His bill is being considered by the Military Affairs Committee. The committee has been informed that if the regulation is permitted to stand the enrolment of students in 1946 will be greatly reduced. Representative Walter H. Judd of Minnesota had introduced an identical bill in the other House.

Two unique bills are H. R. 2969 Eberharter (Pennsylvania), which provides that any physician holding a license to practice in any state shall, when discharged from service, be entitled to receive a certificate granting him the right to practice in any state of his choosing, and S. 837 Langer (North Dakota), which would have the federal government pay to parents \$500 on the birth of their second child, \$750 on the birth of the third and \$1,000 for the fourth and each additional child. The perennial bill H. R. 491 Lemke (North Dakota) opposing the employment of the dog in research has reappeared.

Senators Wagner of New York and Murray of Montana introduced a revised edition of the 1943 health insurance bill (S. 1050). An identical bill was introduced in the House of Representatives at the same time by Congressman Dingell of Michigan (H. R. 3293). Legislation has been introduced in both houses (S. 1072 Johnson Colorado), H. R. 3310 Rankin (Mississippi) and H. R. 3317 Rogers (Massachusetts) providing for the creation of a Department of Medicine and Surgery in the Veterans Administration. Congressman Priest of Tennessee has introduced a bill (H. R. 2550) providing for the creation of a National Neuropsychiatric Institute. Senator Pepper of Florida and some other senators jointly are sponsoring an identical bill in the Senate.

When requested, the Association's position or views on legislation under consideration by committees have always been presented by properly selected representatives.

Conferences.—As the establishment of the Washington office is becoming known among government bureaus, requests for consultation and information are being received. When the requests are of a specific character, they are referred to the particular Council in Chicago for reply. Congressmen also have called for assistance in discussing the value or merit of certain proposals of legislation. The manner in which both representatives of the bureaus and of Congress received the knowledge that the American Medical Association has established and is conducting such an information bureau in Washington has been abundantly gratifying.

Office.—The Washington office is still very much cramped for office space, but we are not the only ones in Washington who are suffering because of lack of space and personnel. The government takes over all of the extra space as it becomes available, and those with priorities take out the best of the personnel; but our future does not look too dark. As for personnel, we hope in time to find an ex-serviceman who will qualify as secretary for us. The friendly reception which has greeted us everywhere that we have gone in Washington leads us to believe that the office has a very bright future.

REGIONAL CONFERENCES

Another feature of the program has been the conduct of regional meetings. The first of these was held back in May 1944, when Dr. Roger I. Lee invited representatives of the New England states to a conference at the Harvard Club of Boston. The director of the Washington office was also invited and outlined the proposed program for that office. Since the 1st of September, five other conferences have been held. The first was in Cincinnati, to which representatives from Ohio, Indiana, Kentucky and West Virginia were invited. The conference was well attended and interest was very encouraging.

The second conference formed a part of an annual conference held by the physicians for the North Central states. Dr. Adson and the director of the Washington office were invited to take part in the program, at which time the plan of the Council was presented and thoroughly discussed.

The Council met in Washington early in December, and at the close of the meeting the third regional conference was held, to which representatives of the Atlantic Coast states were invited. Subsequently other conference have been held. One for the Central states was held at Kansas City, one in Atlanta for the states of the Southeast and later one in Portland, Ore., to which representatives of the West and Northwest were invited.

The program of the conferences has developed and with each conference some changes have been incorporated. At present the forenoon program is given over to the secretaries of various Councils of the American Medical Association, each taking a brief time for outlining the program of his Council and an opportunity is given for discussion after each presentation. In the afternoon the delegates are invited to introduce any subject for discussion that they may choose. In most instances the principal subject has been that of voluntary insurance, each state making a report on what its experience has been and what future program it has outlined. These discussions have been most informative and are proving very helpful. On the whole the program of these conferences is twofold: first, to acquaint the state officials with the program of the Council and the part to be played by the Washington office; second, to make the acquaintance of the state representatives and receive their suggestions as to what they expect of the Council. The attendance has been approximately thirty-five to fifty persons. Minutes are taken, mimeographed and distributed to those in attendance or who were invited to attend.

ADDITIONAL TALKS

In addition to the regional conferences, individual members of the Council have spoken at more than fifty meetings throughout the year. Talks were given before county and state medical societies, and on numerous occasions members of the Council made additional talks before lay groups or appeared on radio programs and discussed the work of the Council.

CONSTRUCTIVE PROGRAM FOR MEDICAL CARE

Perhaps the most effective work done by the Council during the past year was the preparation of the fourteen point "Constructive Program for Medical Care" with the approval of the Board of Trustees of the American Medical Association, which appeared in THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION for July 21, 1945 and was simultaneously released to the newspapers and to the radio throughout the country. This program follows:

CONSTRUCTIVE PROGRAM FOR MEDICAL CARE

AMERICAN MEDICAL ASSOCIATION

This platform was adopted by the Council on Medical Service and Public Relations and the Board of Trustees of the American Medical Association on June 22, 1945

Preamble

The physicians of the United States are interested in extending to all people in all communities the best possible medical care. The Constitution of the United States, the Bill of Rights and the "American Way of Life" are diametrically opposed to regimentation or any form of totalitarianism. According to available evidence in surveys, most of the American people are not interested in testing in the United States experiments in medical care which have already failed in regimented countries.

The physicians of the United States, through the American Medical Association, have stressed repeatedly the necessity for extending to all corners of this great country the availability of aids for diagnosis and treatment, so that dependency will be minimized and independence will be stimulated. American private enterprise has won and is winning the greatest war in the world's history. Private enterprise and initiative manifested

through research may conquer cancer, arthritis and other as yet unconquered scourges of humankind. Science, as history well demonstrates, prospers best when free and unshackled.

Program

The physicians represented by the American Medical Association propose the following constructive program for the extension of improved health and medical care to all the people:

1. Sustained production leading to better living conditions with improved housing, nutrition and sanitation which are fundamental to good health; we support progressive action toward achieving these objectives:
2. An extended program of disease prevention with the development or extension of organizations for public health service so that every part of our country will have such service, as rapidly as adequate personnel can be trained.
3. Increased hospitalization insurance on a voluntary basis.
4. The development in or extension to all localities of voluntary sickness insurance plans and provision for the extension of these plans to the needy under the principles already established by the American Medical Association.
5. The provision of hospitalization and medical care to the indigent by local authorities under voluntary hospital and sickness insurance plans.
6. A survey of each state by qualified individuals and agencies to establish the need for additional medical care.
7. Federal aid to states where definite need is demonstrated, to be administered by the proper local agencies of the states involved with the help and advice of the medical profession.
8. Extension of information on these plans to all the people with recognition that such voluntary programs need not involve increased taxation.
9. A continuous survey of all voluntary plans for hospitalization and illness to determine their adequacy in meeting needs and maintaining continuous improvement in quality of medical service.
10. Discharge of physicians from the armed services as rapidly as is consistent with the war effort in order to facilitate redistribution and relocation of physicians in areas needing physicians.
11. Increased availability of medical education to young men and women to provide a greater number of physicians for rural areas.
12. Postponement of consideration of revolutionary changes while 60,000 medical men are in the service voluntarily and while 12,000,000 men and women are in uniform to preserve the American democratic system of government.
13. Adoption of federal legislation to provide for adjustments in draft regulation which will permit students to prepare for and continue the study of medicine.
14. Study of postwar medical personnel requirements with special reference to the needs of the veterans' hospitals, the regular army, navy and United States Public Health Service.

Respectfully submitted,

E. J. McCORMICK, Chairman
JAMES R. McVAY, Vice Chairman
ALFRED W. ADSON.
LOUIS H. BAKER
W. R. BROOKSHER.
JOHN H. FITZGIBBON.
HERMAN L. KRETSCHMER.
THOMAS A. MCGOLDRICK.
JAMES E. PAULLIN.
OLYN WEST.
THOMAS A. HENDRICKS, Secretary.

REPORT OF THE BOARD OF TRUSTEES

Bureau of Legal Medicine and Legislation

Customarily the annual report of the Bureau covers only the preceding calendar year. Owing to the delayed session of the House of Delegates this year, the present report will include references to matters that have occurred not only during the year 1944 but also during the current year.

CHEMICAL TESTS FOR INTOXICATION

Since 1937 the committee created by the House to study problems of motor vehicle accidents has studied carefully the relation of the action of alcohol to traffic accidents. In this study it has collaborated closely with the Committee on Tests for Intoxication of the National Safety Council. It has on several occasions recommended definite borderline limits for alcoholic influence in terms of amount of alcohol in the suspected drunken driver, and these limits have been approved by the House. In order to promote uniformity in state legislation in this field, the National Safety Council, through its Committee on Tests for Intoxication and with the active collaboration of the Bureau, has formulated a draft of a uniform bill which embodies the borderline limits approved by the House. The draft does not undertake to compel a driver suspected of being drunk to submit to a chemical test for intoxication. It does give legislative recognition of the borderline limits and assures that the results of the tests will be admissible in evidence. This draft was submitted to the Board of Trustees and was approved in principle. A similar approval by the House will be helpful in promoting the enactment of the law. The draft, in form, is an amendment to section 54, act V, of the Uniform Vehicle Code, and reads as follows:

SEC. 54. Persons under the influence of intoxicating liquor or of drugs—(a) It is unlawful and punishable as provided in subdivision (d) of this section for any person who is under the influence of intoxicating liquor to drive or be in actual physical control of any vehicle within this state.

(b) In any criminal prosecution for a violation of subdivision a of this section relating to driving a vehicle while under the influence of intoxicating liquor, the amount of alcohol in the defendant's blood at the time alleged as shown by chemical analysis of the defendant's blood, urine, breath or other bodily substance shall give rise to the following presumptions:

1. If there was at that time five hundredths per cent or less by weight of alcohol in the defendant's blood, it shall be presumed that the defendant was not under the influence of intoxicating liquor.

2. If there was at that time in excess of five hundredths per cent but less than fifteen hundredths per cent by weight of alcohol in the defendant's blood, such fact shall not give rise to any presumption that the defendant was or was not under the influence of intoxicating liquor, but such fact may be considered with other competent evidence in determining the guilt or innocence of the defendant.

3. If there was at that time fifteen hundredths per cent or more by weight of alcohol in the defendant's blood, it shall be presumed that the defendant was under the influence of intoxicating liquor.

4. The foregoing provisions of this subdivision shall not be construed as limiting the introduction of any other competent evidence bearing upon the question whether or not the defendant was under the influence of intoxicating liquor.

(c) It is unlawful and punishable as provided in subdivision d of this subsection for any person who is a habitual user of or under the influence of any narcotic drug or who is under the influence of any other drug to a degree which renders him incapable of safely driving a vehicle to drive a vehicle within this state. The fact that any person charged with a violation of this subsection is or has been entitled to use such drug under the laws of this state shall not constitute a defense against any violation of this subsection.

(d) Every person who is convicted of a violation of this section shall be punished by imprisonment for not less than ten days nor more than one year, or by fine of not less than \$100 nor more than \$1,000, or by both such fine and imprisonment. On a second or subsequent conviction he shall be punished by imprisonment for not less than ninety days nor more than one year, and, in the discretion of the court, a fine of not more than \$1,000.

The commissioner shall revoke the operator's or chauffeur's license of any person convicted under this section.

COMMITTEE TO STUDY THE RELATIONSHIP OF MEDICINE AND THE LAW

At the Cleveland, 1941, session a resolution was introduced calling for the appointment of a committee to survey the relationship of medicine and the law "with particular reference to the manner in which this relationship is exercised in those countries which still cling to the coroner system." It was contemplated that the committee would confer with a corresponding committee of the American Bar Association and that

information developed would be made available to state medical associations. The House referred the resolution to the Board, requesting systematic study of the problem involved.

The Board did give consideration to the resolution and appointed the suggested committee. The American Bar Association likewise designated a collaborating committee. A progress report was submitted to the House at the Chicago, 1943, session and a continuation of the committee was authorized in order that its work might be completed. A further and more comprehensive report was submitted to the House at the Chicago, 1944, session but through inadvertence this report did not receive consideration by a reference committee and therefore was not acted on by the House. It is felt that the House may wish to take some action on the 1944 report of the committee at the forthcoming session in Chicago. Printed copies of the report are available for study.

PRESCRIBING NARCOTICS BY TELEPHONE

The United States Commissioner of Narcotics has called the attention of the Association to the difficulty that is resulting throughout the country because of the frequency with which physicians telephone narcotic prescriptions. This practice, he reports, has resulted in abuse and illicit traffic, many peddlers and addicts using this means to obtain morphine. A federal grand jury investigation has resulted in one community, and the report following the investigation described the facts developed as disclosing a shocking disregard of the law and as reflecting a condition "intolerable and wholly unwarranted." Under existing regulations, the furnishing of narcotics pursuant to telephone advice of physicians is prohibited whether prescriptions covering such orders are subsequently received or not, except in an emergency. In case an emergency does arise, a druggist may deliver narcotics through his employee or responsible agent pursuant to a telephone order only if the employee or agent is supplied with a properly prepared prescription before delivery is made, and this prescription must be turned over to the druggist and filed by him as required by law. As suggested in a Current Comment published in *THE JOURNAL*, Aug. 11, 1945, physicians will aid materially in preventing the abuses referred to by the Commissioner of Narcotics if they restrict orders for narcotics by telephone strictly to actual cases of emergency.

ISONIPECAINE

In the report of the Bureau transmitted to the House in 1944, reference was made to a suggestion by the Commissioner of Narcotics that Demerol, be brought within the purview of narcotic laws. The House of Delegates adopted a recommendation of the reference committee on legislation and public relations in support of restricting the sale of Demerol (isonipeaine) in this manner. A federal law has now been enacted to accomplish this end (Public Law No. 414, 78th Congress). Similar laws have been enacted in twenty-two states: Alabama, California, Connecticut, Georgia, Illinois, Indiana, Iowa, Kentucky, Louisiana, Minnesota, Mississippi, New Jersey, New York, North Dakota, Oklahoma, Oregon, Pennsylvania, South Carolina, South Dakota, Vermont, Virginia and Wisconsin.

INFORMATION FOR MEDICAL OFFICERS

The Bureau has cooperated with the Bureau of Information in supplying medical officers with available information with respect to licensure requirements. A considerable number of such inquiries have been received and answered. They have fallen in one of four general classifications: (1) those relating to reciprocity, (2) those relating to requirements for licensure where the medical officer by reason of entry into service was prevented from obtaining a license, (3) those from graduates of unapproved schools who have inquired if, by reason of military service, the states in which they otherwise would be unable to qualify would grant them licenses and (4) those relating to benefits made available to medical officers by the G. I. Bill of Rights.

Interest has been manifested, too, by a number of medical officers in the bill introduced in Congress by Representative Eberharter of Pennsylvania, H. R. 2969, under the provisions of which a medical officer, on honorable discharge, would be entitled to practice in any state of choice without compliance with the laws of that state provided he was licensed in any

state prior to entry into service. Further comment on this bill will be made later in this report.

Cooperation was additionally given the Bureau of Information in the preparation of its Bulletin for Medical Officers.

ENABLING ACTS FOR MEDICAL SERVICE PLANS

Early in 1945 a compilation was made available of the laws that had been enacted at that time under which nonprofit prepayment medical service plans may be created and operated. This compilation, in pamphlet form, contains verbatim copies of the laws in thirteen states: California, Connecticut, Massachusetts, Michigan, New Hampshire, New Jersey, New York, North Carolina, Ohio, Pennsylvania, Vermont, Virginia and West Virginia. Ready access to these laws will be of value to state medical associations and their attorneys in the preparation of enabling laws for their states.

During the 1945 legislative session, laws with similar objectives were enacted in ten additional states: Florida, Illinois, Iowa, Kansas, Maryland, Minnesota, North Dakota, Rhode Island, Tennessee and Wisconsin. Laws of this character failed of enactment in Colorado and South Dakota. The enabling act of New Hampshire was amended to permit reciprocal relations with medical service corporations of other states.

These new laws will be included in a supplement to the compilation that has already been made available. During 1945 the services of the Bureau were utilized in the drafting of legislation for prepayment medical service plans in a number of states.

COMPULSORY SICKNESS INSURANCE

The current legislative year witnessed a number of proposals in state legislatures looking toward the establishment of compulsory sickness insurance schemes. None passed. The controversy was particularly acute in California, where several bills of this nature were before the legislature, one being commonly referred to as the Governor's Bill and another as the C. I. O. Bill. Other states in which similar legislation was proposed included Connecticut, Massachusetts, Michigan, New Mexico, New York, Wisconsin and Washington. Legislation was also introduced in a number of states to provide a system of compulsory cash benefits for unemployment due to sickness, similar to the Rhode Island law, including California, Colorado, Connecticut, Massachusetts, Minnesota, Montana, Nevada and New Jersey. None passed.

BLOOD BANKS

During 1944 and 1945, laws providing for the establishing of blood banks for civilian use were enacted in Illinois, Michigan, Montana, New Jersey, New York, North Dakota, Ohio and Vermont. Similar legislation failed of enactment in Alabama, California, Indiana and Kansas. In Missouri a bill is still pending.

LAW* FOR ESTABLISHMENT OF MEDICAL SCHOOLS

Legislation was introduced in seven states in 1945 either providing for new medical schools or authorizing studies to determine the advisability of establishing such institutions. In Florida a law became effective without the approval of the governor, authorizing the city of Tampa to establish a state university to include a school of medicine. In Massachusetts a law was enacted designating a commission to investigate the advisability of establishing a state university to include medical, dental, veterinary and osteopathic schools. In North Carolina the board of trustees of the university, with the approval of the governor and the North Carolina Medical Commission, was authorized to expand the two year medical school of the University of North Carolina into a standard four year medical school. In North Dakota there was created a Medical Center Advisory Council with authority, among other things, to formulate plans for a unified program for the improvement of the health of the people of the state, including ways and means for bringing about the complete training of adequate numbers of qualified physicians for the state, both in the general practice of medicine and surgery and in the field of public health. In South Dakota a new law was enacted authorizing an appropriation of \$150,000 to establish, equip and maintain a four year medical school at the South Dakota University. In West Virginia an interim committee was appointed to study the advisa-

bility of establishing a four year school of medicine in the state. In Washington a law was enacted establishing a medical and dental school at the University of Washington. A bill is still pending in Missouri contemplating the establishment of a medical school.

FEDERAL LEGISLATION

Seventy-Eighth Congress

The Seventy-Eighth Congress adjourned sine die Dec. 19, 1944. All legislation not finally acted on prior to adjournment died. During the Seventy-Eighth Congress 9,536 bills, joint, concurrent and simple resolutions, were introduced in the Senate and House. A total of 1,157 laws were enacted. Of the total bills introduced, approximately 390 were of sufficient medical interest to justify the publication of either brief or extended analyses of them in *THE JOURNAL*.

During the closing months of the Congress the following laws of interest to medicine were enacted:

The Public Health Service Act, consolidating and revising the laws relating to the service. Included in this law is a new authorization for an appropriation of \$10,000,000 for the fiscal year ended June 30, 1945 to develop more effective measures for the prevention, treatment and control of tuberculosis. Thereafter, such sums are authorized as may be needed. The law also continued in force a provision that for the duration of the war and for six months thereafter graduates of reputable osteopathic colleges shall be eligible for appointment as "reserve officers in the service." Too, the law authorizes the Surgeon General to make grants-in-aid to universities, hospitals, laboratories and other public or private institutions and to individuals for such research projects as are recommended by the National Advisory Health Council or, with respect to cancer, recommended by the National Advisory Cancer Council. The limit on the authorization of appropriation for venereal disease control was removed and the authorized appropriation for aid in establishing and maintaining public health services in the states was increased from \$11,000,000 to \$20,000,000 annually.

The G. I. Bill of Rights. A detailed analysis of this law was prepared by the Bureau and published in *THE JOURNAL*, July 15, 1944. Certain provisions of it are of particular interest to physicians in service, namely those relating to refresher and postgraduate courses and those relating to the guaranty of loans for the purchase of equipment and supplies to be used in a gainful occupation. The benefits of this law are available to commissioned and noncommissioned personnel alike. Prior to June 29, 1945 much uncertainty obtained as to whether a commissioned officer of the Public Health Service would be entitled to the full benefits of this new law. On that date the President, by Executive Order No. 9575, declared the commissioned corps of the Public Health Service to be a military service and by that action removed all doubts as to the availability of the benefits of the law to members of such commissioned corps.

Additional appropriations for the EMIC program. Two additional appropriations were made available to continue this program, one in the amount of \$6,700,000 and the other in the amount of \$42,800,000 plus \$43,000 for administrative expenses of the Children's Bureau. Through the Seventy-Eighth Congress a total of \$73,743,000 has been specifically allotted by Congress for providing obstetric and pediatric care to the beneficiaries of the program. To initiate the program \$390,477 from the regular appropriation authorized for maternal and child health activities was used.

Limitation of production of opium. A new law requests the President to approach the governments of all opium-producing countries throughout the world, urging on them that they take immediate steps to limit and control the growth of the opium poppy and the production of opium and its derivatives to the amount actually required for strictly medicinal and scientific purposes.

Services in the Medical Reserve Corps in relation to pay. By reason of a decision of the Comptroller General, former members of the Medical Reserve Corps were denied the right to include the time they served in that corps in the computation of their pay. A law was enacted by the Seventy-Eighth Congress under which such service may be included.

Department of Agriculture Organic Act of 1944. This law contains a provision that none of the money made available in the Department of Agriculture Appropriation Act, 1944, for loans, grants and rural rehabilitation may be used in the promotion or aid of any program of medical care which prevents a patient from having the services of any practitioner of his choice so long as there is a compliance with state laws. This restriction, however, is not applicable to the promotion or aid of a program of medical care where a majority of the participants within the program group elect to confine their choice of practitioners to a list of available licensed practitioners selected by them.

Seventy-Ninth Congress

The first session of the Seventy-Ninth Congress convened Jan. 3, 1945 and is in progress at the time this report is being prepared. Of the many important bills of medical interest which have been introduced, the following deserve consideration:

Industrial Health Under Jurisdiction of Labor Departments.—A bill, H. R. 525, is pending in the House of Representatives, with a favorable committee report, to provide for cooperation with state agencies administering labor laws in establishing and maintaining safe and proper working conditions in industry and in the preparation, promulgation and enforcement of regulations to control industrial health hazards. An appropriation of \$5,000,000 will be made available annually to the Secretary of Labor for allotment to cooperating state agencies administering labor laws. While the bill provides that, in the operation of plans to be developed, the available services and facilities of public health authorities in the field of industrial hygiene shall be utilized, sums that will be allotted must be expended in accordance with rules and regulations prescribed by the Secretary of Labor and plans jointly developed by the agency administering labor laws of the states and the Division of Labor Standards and approved by the Secretary of Labor. This bill, if enacted, will confer on labor departments, on federal and state levels, jurisdiction over industrial health problems. A companion bill, S. 1271, has been introduced by Senator Johnston, South Carolina, for himself and Senator Ball, Minnesota. It is pending in the Senate Committee on Education and Labor.

At the Kansas City, 1936, session of the House, a resolution was adopted relating to industrial health hazards in which was expressed the conviction that "any active efforts by governmental agencies to study and to take measures tending to eliminate occupational diseases should be carried out under the supervision of the city, state or federal departments of health in this country." On July 8, 1939 the Council on Industrial Health adopted a resolution, subsequently approved by the Board of Trustees in February 1940, to the effect that "the interests of the industrial worker will best be served by continued concentration of industrial hygiene in the federal and state health departments.

Legislation similar to the pending bill was introduced in the Seventy-Eighth Congress. At the Chicago, 1944, session a resolution was introduced in the House expressing opposition to the legislation and reaffirming the belief that "any extension of governmental activities in the field of industrial health and hygiene should be developed under the supervision and guidance of the U. S. Public Health Service and state departments of health." The Reference Committee on Legislation and Public Relations, in recommending disapproval of the resolution, said "Your reference committee feels that the work described in H. R. 4371 could best be done through the state and local authorities with monies allotted to them by the Secretary of Labor rather than through the United States Public Health Service as suggested in this resolution." The report of the reference committee was adopted.

In the report of the Bureau submitted to the House last year, reference was made to the then pending industrial hygiene bill. The report of the Bureau was referred to the Reference Committee on Report of Board of Trustees and Secretary, which committee, in referring to the industrial hygiene bill, said "A pending bill conferring jurisdiction over industrial hygiene on labor departments requires additional study." The report of the reference committee was adopted.

Two other actions taken by the House last year involved to a great extent the same principle involved in the industrial hygiene bill. The House adopted a resolution to transfer the EMIC program from the Department of Labor to the United States Public Health Service. It recorded its approval of the Miller bill proposing to transfer all government agencies dealing with health to the United States Public Health Service.

In view of the foregoing, the House may wish to reconsider the implications inherent to H. R. 525 and to clarify its opinion with respect to the bill.

National Neuropsychiatric Institute.—Companion bills are pending respectively in the Senate Committee on Education and Labor and in the House Committee on Interstate and Foreign Commerce proposing to enact a National Neuropsychiatric Institute Act, S. 1160, introduced by Senator Pepper, Florida, for himself and Senator Thomas, Utah, Senator Tunnell, Delaware, Senator Hill, Alabama, Senator Murray, Montana, Senator LaFollette, Wisconsin, and Senator Aiken, Vermont, and H. R. 2550, introduced by Representative Priest, Tennessee. This legislation would establish in the United States Public Health Service a National Neuropsychiatric Institute with the following functions: (1) to conduct researches, investigations, experiments and demonstrations relating to the cause, diagnosis and treatment of neuropsychiatric disorders; (2) to assist and foster similar research activities by other agencies, public and private, and to promote the coordination of all such researches and activities and the useful application of their results; (3) to train personnel in matters relating to neuropsychiatric disorders, and (4) to develop and assist states in the use of the most effective methods of prevention, diagnosis and treatment of neuropsychiatric disorders. A National Advisory Mental Health Council will be created to function with the Surgeon General of the Public Health Service, consisting of the Surgeon General, as chairman, and six members appointed by him with the approval of the Federal Security Administrator.

The Surgeon General will be authorized, through the institute, (1) to conduct and foster researches and experiments relating to the cause, prevention and methods of diagnosis and treatment of neuropsychiatric disorders; (2) to promote the coordination of researches conducted by the institute and similar researches conducted by other agencies; (3) to make available research facilities of the service to appropriate public authorities and scientists; (4) to make grants-in-aid to universities, hospitals, laboratories and other public or private institutions, and to individuals for such research projects as are recommended by the National Advisory Mental Health Council; (5) to admit voluntary patients at the institute to be established for the purpose of study; (6) to provide for the dissemination of information obtained as a result of the research carried on relating to neuropsychiatric disorders; (7) to establish fellowships in the institute; (8) to provide for training and instruction in matters relating to neuropsychiatric disorders, and (9) to assist states, counties, health districts and other political subdivisions of the states and nonprofit agencies in establishing and maintaining adequate measures for the prevention, treatment and control of such disorders.

The National Advisory Mental Health Council will be authorized (1) to review research projects or programs submitted to or initiated by it, (2) to assemble information concerning studies being carried on in the United States or any other country with respect to neuropsychiatric disorders and (3) to review applications for grants-in-aid and to certify to the Surgeon General its approval.

An appropriation of \$4,500,000 is to be authorized for the erection and equipment of suitable and adequate hospital buildings and facilities. An additional appropriation of \$10,000,000 for the fiscal year ending June 30, 1946 will be authorized to enable the Surgeon General to carry out the general objectives of the legislation. Thereafter for each fiscal year there will be authorized a sum sufficient to carry out its purposes.

Hearings were scheduled on the House bill, September 18, by a subcommittee of the House Committee on Interstate and Foreign Commerce.

A resolution was presented from the Section on Nervous and Mental Diseases at the New York, 1940, session endorsing the general objectives of legislation setting up a "Central Neuropsychiatric Institute to be established in the Public Health Service to carry on research in nervous and mental diseases" and advocating that such an institute have at its disposal funds to be allotted to competent groups throughout the country approved by a National Neuropsychiatric Advisory Council. At the time this resolution was presented to the House, no legislation was pending in the Congress relating to this matter. The House refused to adopt the resolution.

Hospital Construction Act.—Pending legislation contemplates the enactment of a Hospital Construction Act. The Senate bill, S. 191, was introduced by Senator Hill, Alabama, for himself and Senator Burton, Ohio, and is pending in the Senate Committee on Education and Labor. Four companion House bills are pending in the House Committee on Interstate and Foreign Commerce: H. R. 2498, introduced by Representative Neely, West Virginia, H. R. 2755, introduced by Representative Patrick, Alabama, H. R. 3561, introduced by Representative Priest, Tennessee, and H. R. 3845, introduced by Representative Snyder, Pennsylvania.

The broad objectives of this legislation have been approved by the Board of Trustees. It contemplates for the first year of its operation a total federal appropriation of \$110,000,000 earmarked as follows: \$5,000,000 to assist states to inventory existing hospitals, to survey the need and to develop a program for new construction, \$5,000,000 to assist state agencies to meet their administrative expenses in carrying out state plans, and \$100,000,000 for the construction of public and other nonprofit hospitals. Thereafter so much will be appropriated as the Congress may deem necessary. The term "hospital" is defined by this legislation to include "public health centers and general, tuberculosis, mental, chronic disease and other types of hospitals and related facilities, such as laboratories, outpatient departments, nurses' home and training facilities, and central service facilities operating in connection with hospitals, but shall not include any hospital furnishing primarily domiciliary care." A "public health center" is defined to mean "a publicly owned facility for the provision of public health services and medical care, including related facilities such as laboratories, clinics and administrative offices in connection with public health centers." On a federal level this hospital building program will be under the direction and supervision of the Surgeon General of the United States Public Health Service aided by a Federal Advisory Council, all appointed members of which will be appointed by the Administrator of the Federal Security Agency. The Surgeon General will serve as chairman ex officio of the council. On a local level, a state agency must be designated in plans submitted for approval as the administrative agency.

Hearings on the Senate bill were conducted by the Senate Committee on Education and Labor, Feb. 26, 27 and 28 and March 12, 13 and 14, 1945. Representatives of the Association participated in these hearings and recorded the approval of the Association to the general principles of the legislation. No further action has been taken by the Senate committee. As this report is being prepared, hearings have been scheduled on the legislation by the House Committee on Interstate and Foreign Commerce and a representative of the Association will participate in those hearings too.

Since this legislation contemplates state action to designate agencies on a state level to administer the program, to make the surveys of existing facilities and to formulate plans for the construction of additional facilities during the 1945 legislative season, the following twenty states enacted legislation anticipatory of the passage of the federal law: Alabama, Delaware, Florida, Georgia, Illinois, Indiana, Maine, Maryland, Montana, New Mexico, Oklahoma, Oregon, Rhode Island, South Dakota, Texas, Utah, Vermont, Virginia, Washington and West Virginia. In the main, state departments of health in these states were designated as the state agency to function under the federal law.

An analysis of the provisions of the proposed federal law was prepared by the Bureau and published in *THE JOURNAL* for Jan. 27, 1945. Reprints are available.

Federal Licensure of Physicians.—A bill has been introduced in the House of Representatives by Representative Eberharter, Pennsylvania, relating to physicians and dentists who have served in the land or naval forces during the war period, H. R. 2969. It is pending in the House Committee on Military Affairs. This bill proposes that any individual who served as an officer in the Medical Department of the Army or Navy during the war period and was discharged or separated from service under honorable conditions and who, prior to such discharge or separation, held a license to practice medicine or dentistry under the laws of a state shall be entitled to receive a certificate which will authorize him to engage, in any state, in the practice of the particular class of medicine or dentistry covered by the state license held by him. It is contemplated that the Secretary of War and the Secretary of the Navy shall jointly prescribe regulations with respect to the making of application for, and the issuance of, such certificates, which will be issued to the medical or dental officer at the time of his discharge or separation from service. No action has been taken by the Congress on this bill, and it is doubtful that it can be constitutionally enacted. The theory of the bill, apparently, is that the certificates to be issued will legalize the practice of medicine or dentistry by the holder in any state without compliance with the requirements of laws of that state imposing requirements to be met by those desiring to engage in practice. To that extent the legislation would constitute a usurpation of authority by the federal government that the Supreme Court has said lodges with the individual states. That court has held that the direct control of medical practice in the states is beyond the power of the federal government (*Linder v. United States*, 268 U. S. 5). A similar conclusion has been reached by a United States District Court (*Starnes v. Rose*, 282 Fed. 336).

The Wagner-Murray-Dingell Bill.—The 1945 version of this legislation was introduced in the Senate by Senator Wagner, New York, and Senator Murray, Montana, as S. 1050 and in the House of Representatives by Representative Dingell, Michigan, as H. R. 3293. The bills are pending, respectively, in the Senate Committee on Finance and the House Committee on Ways and Means, the same committees to which similar bills in the Seventy-Eighth Congress were referred. No hearings have as yet been scheduled.

The text of the pending legislation contains 185 pages, 95 more pages than its predecessor. In broad outline it embraces the following: A new title will be added to the Public Health Service Act for grants and loans for hospitals and health center construction. This title corresponds, with significant exceptions, to the provisions of the Hill-Burton hospital construction bill. It removes some of the safeguards that are contained in the latter bill, particularly in reference to the functions of the Federal Advisory Council, and proposes a ten year building program for which \$950,000,000 is to be authorized. The pending legislation provides for grants and services to develop more effective measures for venereal disease and tuberculosis control and for the expansion and improvement of public health work. It proposes grants for maternal and child health services, for services for crippled children and for child welfare services. It would make available grants to states for public assistance to needy individuals, including medical care for such individuals. The most important section from the point of view of medicine, section 9, proposes to amend title II of the Social Security Act to provide a national social insurance system. The amended title would provide for (a) a compulsory system of sickness insurance, (b) a national system of unemployment and temporary disability insurance, including cash benefits for disability from sickness which causes unemployment, (c) retirement, survivor and extended disability benefits, (d) a national social insurance trust fund, (e) credit for military service, (f) extended coverage to include an estimated additional 15,000,000 persons, (g) contributions or taxes by employers, employees and the self employed and (h) certain general provisions to apply to the operation of the title.

The national social insurance system will be financed in general from a trust fund established by a 4 per cent employer and a 4 per cent employee tax on wages and salaries up to the first \$3,600 a year paid or received after Dec. 31, 1945. The tax

to be levied on the self employed will be 5 per cent of the market value of services subject to the same ceiling limitation. The taxes to be paid by states and localities and by their employees will be 2.5 per cent of the first \$3,600. The taxes that employers and employees will pay to finance the system will be distributed as follows:

Division of Taxes

Program	Employer	Employee	Total
1. Retirement, survivors and, extended disability insurance	1.0%	1.0%	2.0%
2. Medical care and hospitalization insurance	1.5%	1.5%	3.0%
3. Unemployment insurance	1.0%	1.0%	2.0%
4. Temporary disability insurance.....	0.5%	0.5%	1.0%
Total taxes	4.0%	4.0%	8.0%

The bill itself does not specifically undertake to make medical care available to the indigent class. It does provide that benefits may be extended to noninsured persons on behalf of whom equitable payments are made or assured by public agencies of the United States, the several states, or any of them or their political subdivisions. On behalf of the legislation, it is claimed that its enactment will not necessarily result in the displacement of existing prepayment medical service and hospitalization plans. The legislation does not refer to such plans *co nomine* but does direct the Surgeon General, after consultation with the Advisory Council as to questions of general policy and administration and with the approval of the Federal Security Administrator, to make agreements or arrangements with private agencies or institutions, or with private persons or groups of persons, to utilize their services and facilities.

A detailed analysis of the part of the legislation proposing to engraft on the social security program a system of compulsory sickness insurance was prepared by the Bureau and published in *THE JOURNAL*, June 2, 1945. Reprints are available. Whether or not hearings will be scheduled on this legislation, either by the Senate or by the House committee, remains, at the time of this report, a matter for conjecture. Consideration must be given to the possibility of developments along three avenues. The House of Representatives has authorized its Committee on Ways and Means to expend not in excess of \$50,000 in a study of the entire social security setup. This study will embrace, it is contemplated, the need for the amendment and expansion of the Social Security Act, with particular reference to old age and survivors' insurance and the problems of coverage, benefits and taxes. It is understood that public hearings will be held by the committee in the course of its investigation, and it is entirely possible that during the course of such hearings some of the proposals contained in the Wagner-Murray-Dingell bill will receive consideration. It has been suggested, too, that proponents of the pending legislation, realizing the difficulty that the passage of the omnibus bill faces, will make an effort to accomplish their purpose by obtaining the enactment of separate bills to accomplish the overall objectives of S. 1050. The third development that must be considered has relation to what the President will recommend to the Congress as intimated in his message of September 6. In this message he said, in part:

I shall shortly recommend a national health program to provide adequate medical care for all Americans and to protect them from financial loss and hardships resulting from illness and accident. I shall also communicate with the Congress with respect to expanding our social security system and improving our program of education for our citizens.

He called attention to the fact that the Congress has been considering legislation with respect to the construction of hospitals and health centers throughout the country and said that the federal government must continue to recognize its obligation to maintain and improve the health of the nation by providing federal grants where necessary for the construction of hospitals and health centers. He repeated President Roosevelt's suggestion for an economic bill of rights, which included the right to adequate medical care and the opportunity to achieve and enjoy good health.

If the President does submit a concrete program to the Congress, that program will without doubt have considerable influence on the prospects of action on the Wagner-Murray-Dingell bill.

Maternal and Child Welfare Act of 1945.—Pending legislation proposes a greatly expanded federal program for the health and welfare of mothers, infants and children and for services to crippled children. In the Senate a bill, S. 1318, was introduced by Senator Pepper and nine other members of the Senate Committee on Education and Labor, to which committee it was referred. Similar bills have been introduced in the House by Representative Norton, New Jersey (H. R. 3922), by Representative Kelley, Pennsylvania (H. R. 3994), and by Representative Patterson, California (H. R. 4059). They are pending in the House Committee on Labor, of which Representative Norton is chairman.

Senator Pepper has described the genesis of this legislation in this manner:

In administering the program of services for children under the Social Security Act, the Children's Bureau has sought the advice and counsel of outstanding physicians, social workers and members of other professions who are authorities in the fields of child health and child welfare, and of citizen groups concerned with the problems of children. For the past year the Bureau's technical and general advisory committees have been reviewing and reappraising the programs in relation to present needs. Their recommendations, in turn, have been studied by the National Commission on Children in Wartime. [Note: This commission was appointed by the chief of the Children's Bureau and was formerly known as the Children's Bureau Commission on Children in Wartime.] Members of this commission include the chairmen of the bureau's advisory committee and representatives of labor, farm, women's, church and professional groups.

The present bill embodies the essential recommendations of this distinguished group of citizens, which has released a report entitled "Building the Future for Children and Youth."

A detailed analysis of the provisions of this legislation was prepared by the Bureau and published in THE JOURNAL for Aug. 11, 1945. Reprints are available.

For the fiscal year ending June 30, 1946 an appropriation of \$100,000,000 is contemplated. Of this, \$50,000,000 is earmarked for maternal and child health services, \$25,000,000 for services to crippled children, \$20,000,000 for child welfare services and \$5,000,000 for administrative expenses of the Children's Bureau. In essence, the legislation would extend and greatly expand the EMIC program. It would make available to mothers and children medical care irrespective of financial needs. A "child" in contemplation of the legislation is any person under 21 years of age. All plans for the programs proposed must be approved by the Children's Bureau, and the chief of that bureau will formulate all general policies with respect to maternal and child health services and services for crippled children after consultation with a conference of health officers and an advisory committee to be appointed by her.

Senator Pepper has described this legislation as constituting a modest beginning and intimates that an annual appropriation of \$1,000,000,000 will be required adequately to provide the necessary services for children.

Additional Funds for EMIC Program.—Prior to the termination of the fiscal year ended June 30, 1945 the Congress appropriated a supplemental sum in the amount of \$2,200,000 to finance the program during the remainder of that fiscal year. In the regular appropriation bill for the fiscal year ending June 30, 1946 the sum of \$44,189,500 was made available. A new proviso was added to the language under which the Children's Bureau is forbidden to promulgate or carry out any regulation relating to the care of obstetric cases which discriminates between persons licensed under state law to practice obstetrics. This new proviso declares that any state plan which provides standards for professional obstetric services in accordance with the laws of the state shall be approved by the chief of the Children's Bureau.

Reorganization of Government Agencies; Federal Department of Health and Welfare.—Legislation is pending looking toward a reorganization of government agencies, S. 1120, introduced by Senator Overton, Louisiana, for Senator McCarran, Nevada. It is pending in the Senate Committee on the Judiciary, and public hearings are under way. No new department

of the federal government could be created under this legislation, but it authorizes the President to examine and formulate plans for the reorganization of all agencies of the government for the purpose, among others, of coordinating, grouping and consolidating agencies and functions of the government, as nearly as may be, according to major purposes. Any plan that is formulated by the President must be submitted to the Congress for approval. A similar reorganization measure was enacted by the Seventy-Sixth Congress in 1939, and the present bill proposes to extend the authority conferred on the President by that law. The enactment of the reorganization measure now pending was recommended by the President in his message to the Congress on May 24, 1945.

No action has been taken by the Congress on the Miller bill to establish a Federal Department of Health, H. R. 1391. It is pending in the House Committee on Expenditures in the Executive Departments. It would establish at the seat of government an executive department to be known as the Department of National Health, "at the head of which shall be the Secretary of National Health, who shall be appointed by the President, by and with the advice and consent of the Senate, and shall receive the same salary as the heads of other executive departments." There will be assembled in the new department, the bill proposes, all activities of the federal government relating to health.

Rumor persists that efforts will soon be made to create either a Department of Welfare or a Department of Health and Welfare in the federal government. A recent report of the Woman's Foundation recommends such action by the Congress and suggests that there be created in the department four divisions, one each for health, education, welfare and social insurance, and recreation.

Medical Care for Recipients of Public Assistance.—Representative Coffee, Washington, has reintroduced his bill to provide medical care for recipients of public assistance, H. R. 1820. It is pending in the House Committee on Ways and Means. It proposes for the first year of its operation an appropriation of \$18,000,000 for allotments to states that have developed plans approved by the Social Security Board. Thereafter, so much as is necessary will be authorized. The term "medical care" is defined to include such services, supplies and appliances for the diagnosis, cure, mitigation, treatment or prevention of disease, or for the purpose of "affecting any structure or function of the body," as may be approved by the Social Security Board.

Medical care will be provided, it is contemplated, (1) by the state agency administering or supervising the administration of the plan or (2) by other agencies of the state or political subdivision, in accordance with agreements authorized in regulations by the Social Security Board. Medical care might be provided directly by the state or other agency or indirectly through payments by the state or other agency to the person or persons furnishing the care.

A somewhat different approach to this problem is suggested in a bill introduced by Congressman Miller, Nebraska, H. R. 1442. It also is pending in the House Committee on Ways and Means and would authorize federal grants to the states to provide medical, surgical and hospital care to beneficiaries of old age assistance either through the purchase of insurance or through administration of a plan by or under the supervision of a state agency. It specifically requires that a state plan must "provide for cooperation with medical, health, nursing and welfare groups and organizations."

As indicative of the number of persons who might qualify for medical care under this legislation, attention is called to the fact that in June 1944 more than 2,000,000 needy old people were receiving old age assistance, about one fifth of the total aged population. During the same period approximately 261,000 families were receiving aid in behalf of some 653,000 children, and assistance payments went to nearly 74,000 needy blind persons.

G. I. Bill of Rights.—A considerable number of bills are pending to clarify and liberalize the provisions of the Servicemen's Readjustment Act of 1944. Action has been taken on only one of these bills, H. R. 3749, introduced by the chairman

of the House Committee on World War Veterans' Legislation, Representative Rankin, Mississippi. It has passed the House and is now pending in the Senate Committee on Finance. In addition to liberalizing the loan provisions of the existing law, this bill would effect certain changes in the provisions relating to the education of veterans. It would provide that courses may be initiated four years after the date of discharge of the veteran or the termination of the war and that no course could extend beyond nine years after the termination of the war; it would provide for short intensive postgraduate or vocational training courses of less than thirty weeks; it would authorize correspondence courses of education or training and would increase the subsistence allowance of a veteran undergoing training or pursuing a course of education from \$50 to \$60 a month, if the veteran is without dependents, and from \$75 to \$85 a month if the veteran has dependents.

A Senate bill, S. 1176, introduced by Senator Pepper, Florida, would amend existing law (1) to make benefits available regardless of whether or not education was impeded, delayed, interrupted or interfered with by reason of entry into service; (2) to remove the requirement that the educational course must be initiated not later than two years after discharge or termination of the war; (3) to remove the distinction between veterans over 25 years at the time of induction and those under this age; (4) to add special provisions for qualifying veterans who wish to complete preprofessional and professional courses of education, extending the maximum benefit to seven years regardless of length of service, and (5) to increase the monetary dependency benefits to veterans obtaining education. This bill is pending in the Senate Committee on Finance.

Under the original law a veteran is permitted to pursue a course of education in a school that has been certified to the Veterans Administration by an appropriate state agency as being qualified to give adequate courses of instruction. In a number of instances, state agencies have certified to the Veterans Administration that designated sectarian schools of the healing art, osteopathic, chiropractic and naturopathic, are so qualified. The effect of this certification is that at government expense veterans will be offered courses in such limited branches of the healing art. The Committee on Postwar Medical Service has taken cognizance of this situation and has urged the governors of the several states to take all due precautions to assure that no school of the healing art is certified to the Veterans Administration which is not fully qualified to give adequate and scientific instruction.

Aid to the Physically Handicapped.—The Seventy-Eighth Congress directed the House Committee on Labor, or a subcommittee thereof, to study the extent and character of aid given to the physically handicapped. A special committee was created to make the study, of which Representative Kelley of Pennsylvania was made chairman. In making the study a series of hearings has been scheduled, in some of which representatives of the Association have participated. The evidence submitted at these hearings has been published in eight parts. It relates to the aid given to the blind, to victims of poliomyelitis, to the deaf and hard of hearing, to those having orthopedic impairments, to other handicapping conditions and to the extent to which federal aid is now available to the handicapped. Further hearings are in progress at which particular attention is being given to questions related to amputations and the problems faced by amputees.

The resolution under which the Kelley subcommittee functions contemplates that recommendations for legislation will be submitted as the result of the study. It may be anticipated, therefore, that such recommendations may be submitted to the Seventy-Ninth Congress.

Health Programs for Government Employees.—Bills are pending in the Senate and House proposing to provide for health programs for government employees, S. 406, introduced by Senator Downey, California, and H. R. 2716, introduced by Representative Randolph, West Virginia. These bills are identical with the exception that the Senate bill contains a provision under which osteopaths would be permitted to participate in such programs. It is contemplated that any program to be developed under this legislation would be limited

to (1) treatment of minor illnesses except in an emergency or injury or illness sustained while in the performance of the employee's duty in accordance with the United States Employees' Compensation Act, (2) preemployment and other examinations, (3) referral of employees to private physicians and dentists and (4) education and preventive programs relating to health, including the alleviation of health hazards in the working environment. The House version of this legislation has been favorably reported by the House Committee on the Civil Service.

Penicillin.—Legislation was introduced to amend the Federal Food, Drug and Cosmetic Act by providing for the certification of batches of drugs composed wholly or partly of any kind of penicillin or any of its derivatives, H. R. 3266, introduced by Representative Lea, California. This bill has passed the House and Senate and was approved by the President, July 6, 1945, as Public Law No. 139. The language of it is similar to that of a law previously enacted by the Congress safeguarding the purity of insulin.

Dangerous Drugs.—Representative Robertson, Virginia, introduced H. R. 2348, a bill to provide for the coverage of certain drugs under the federal narcotic laws. It passed the House and subsequently the Senate in an amended form. The Senate amendments have not as yet been accepted by the House. In the language of the House Committee on Ways and Means, the purpose of this legislation is to provide a prompt and convenient method for bringing under the control of the federal narcotic laws any newly discovered synthetic drug which is determined, after appropriate inquiry, to possess the same or similar dangerous, habit forming or habit sustaining qualities as morphine or cocaine.

Vivisection.—There has been reintroduced in the House of Representatives a bill to prohibit experiments on living dogs in the District of Columbia, H. R. 491, introduced by Representative Lemke, North Dakota. This bill provides that it shall be a misdemeanor for any person to experiment or operate in any manner whatsoever on any living dog in the District of Columbia for any purpose other than the healing or curing of the dog. It is pending in the House Committee on the District of Columbia.

Chiropractors and the United States Employees' Compensation Act.—Bills are pending to permit chiropractors to treat beneficiaries of the United States Employees' Compensation Act, S. 178, introduced by Senator Murdock, Utah, and H. R. 610, introduced by Representative Tolan, California. The bills are pending, respectively, in the Senate Committee on Education and Labor and in the House Committee on the Judiciary. A subcommittee of the Senate Committee scheduled a hearing on this legislation at which representatives of the Association appeared in opposition. No committee action has followed.

Optometry and Podiatry Corps in the Army Medical Department.—Pending legislation, H. R. 3755, introduced by Representative Short, Missouri, proposes to establish an Optometry Corps in the Medical Department of the United States Army. The bill was referred to the House Committee on Military Affairs. Following a favorable report by that committee, the bill was passed by the House. Another bill, H. R. 1998, introduced by Representative Hoch, Pennsylvania, contemplates the establishment of a Chiropody Corps in the Medical Corps of the Army. This bill was referred to the House Committee on Military Affairs, and no action has been taken on it up to the time of preparation of this report.

Benefits for Railroad Employees.—Legislation is pending to increase materially the benefits now available to railroad employees under the Railroad Retirement Acts and the Railroad Unemployment Insurance Act. The Senate bill, S. 293, was introduced by Senator Wagner, New York, for himself and Senator Wheeler, Montana. It is pending in the Senate Committee on Interstate Commerce. No action has been taken on it. The House bills were introduced by Representative Jennings, Tennessee (H. R. 1102) and by Representative Crosser, Ohio (H. R. 1362) and are pending in the House Committee on Interstate and Foreign Commerce. Extended hearings on the House bills have been in progress.

In addition to providing cash benefits for periods of unemployment generally, this legislation specifically provides for cash benefits for periods of sickness resulting in unemployment and cash benefits for antepartum and postpartum maternity periods. It would authorize the federal administrative agency to enter into agreements or arrangements with physicians, hospitals, clinics or other persons for securing the examination, physical, medical, mental or otherwise, of persons claiming, entitled to or receiving sickness or maternity benefits and the performance of services or the use of facilities in connection with the execution of statements of sickness which must be filed by employees to obtain benefits. Similar legislation was introduced in the Seventy-Eighth Congress and was referred by the Board of Trustees to the Council on Medical Service and Public Relations for study and attention. The pendency of the present bills has been called to the attention of the Washington office of the Council.

Extension of Social Security Program. Numerous bills are pending proposing to extend and expand the social security program, other than legislation previously referred to in this report. It seems unlikely, however, that any action will be taken on them pending the outcome of the investigations that have been authorized to determine whether or not the program should be expanded. Reference will be made here to only one additional bill, S. 1188, introduced by Senator Green, Rhode Island, and pending in the Senate Committee on Finance. This bill is patterned after the legislation originally introduced in the Seventy-Seventh Congress by Representative Elliot and reintroduced in the Seventy-Eighth Congress by Senator Green. The previous legislation was analyzed by the Bureau in *THE JOURNAL*, Sept. 26, 1942. The present bill, as did its predecessors, provides disability and hospitalization benefits for employees and in addition would authorize the Social Security Board to provide for the furnishing of medical, surgical, institutional, rehabilitation or other services to individuals entitled to disability benefits if such services will aid in enabling such individuals to return to or resume their work.

Dental Health Programs. Three bills are pending to provide assistance to states in developing and maintaining dental health programs: S. 1099, introduced by Senator Aiken, Vermont, for himself and Senator Pepper, Florida, H. R. 3412, introduced by Representative Brehm, Ohio, and H. R. 3414, introduced by Representative Traynor, Delaware. The Senate bill is pending in the Committee on Education and Labor and the House bills in the House Committee on Interstate and Foreign Commerce. Another bill, also pending in the Senate Committee on Education and Labor, is S. 190, introduced by Senator Murray, Montana, to provide for, foster and aid in coordinating research relating to dental diseases and conditions and to establish the National Institute of Dental Research in the National Institute of Health of the United States Public Health Service. Hearings have been concluded on the two Senate bills. This legislation is sponsored by the American Dental Association.

Federal Programs to Promote Scientific Research. Under date of July 5, 1945 the director of the Office of Scientific Research and Development, Dr. Vannevar Bush, submitted to President Truman a report outlining a suggested federal program to promote scientific research and education. This report set forth five principles as basic to any such program:

1. Whatever the extent of support may be, there must be stability of funds over a period of years so that long range programs may be undertaken.

2. The agency to administer such funds should be composed of citizens selected only on the basis of their interest in and capacity to promote the work of the agency. They should be persons of broad interest in and understanding of the peculiarities of scientific research and education.

3. The agency should promote research through contracts or grants to organizations outside the federal government. It should not operate any laboratories of its own.

4. Support of basic research in the public and private colleges, universities and research institutes must leave the

internal control of policy, personnel and the method and scope of the research to the institutions themselves.

5. While assuring complete independence and freedom for the nature, scope and methodology of research carried on in the institutions receiving public funds, and while retaining discretion in the allocation of funds among such institutions, the federal agency must be responsible to the President and to the Congress.

The report recommended the broad outline of a bill for the enactment of Congress, including the suggested creation of a National Research Foundation. This foundation, the report suggested, should develop and promote a national policy for scientific research and scientific education, should support basic research in nonprofit organizations, should develop scientific talent in American youth by means of scholarships and fellowships, and should by contract and otherwise support long range research on military matters. Identical bills are pending in the Senate and the House of Representatives to implement the recommendations of the report. The Senate bill, S. 1285, was introduced by Senator Magnuson of Washington and is pending in the Senate Committee on Commerce. The House bills, H. R. 3852, introduced by Representative Mills, Arkansas, and H. R. 3860, introduced by Representative Randolph, West Virginia, are pending in the House Committee on Interstate and Foreign Commerce.

Subsequent to the introduction of these three bills, Senator Kilgore, West Virginia, for himself and Senator Johnson, Colorado, and Senator Pepper, Florida, introduced S. 1292 relating also to scientific research. This bill embodies principles which the Subcommittee on War Mobilization of the Senate Military Affairs Committee, on the basis of extensive studies made over the past two years, has set up as desirable in any legislation designed to meet the postwar scientific needs of the nation. It is pending in the Senate Committee on Military Affairs.

Other bills relating to scientific research are pending. Representative May, Kentucky, introduced H. R. 3440, which has passed the House and is pending in the Senate Committee on Naval Affairs. Senator Byrd, Virginia, has introduced S. 825, which is pending in the Senate with a favorable committee report. Senator Fulbright, Arkansas, has introduced S. 1236, which is pending in the Senate Committee on Commerce.

An analysis of all the pending bills relating to scientific research was prepared by the Bureau and published in *THE JOURNAL*, Aug. 11, 1945. Reprints are available. With the exception of the three bills designed to implement the recommendations contained in the Bush report, the pending bills differ in many details, and that fact was given recognition by Senator Kilgore at the time he introduced his bill. After referring to the other pending legislation, he expressed the hope that arrangements could be made for joint hearings "so that the issues presented by these different bills can be clarified and agreement reached at an early date on the scope of research needed in the interest of national security and also on the details of organization and administration so essential to the success of any national program of scientific research." Present indications are that joint or consolidated hearings will be scheduled for the month of October.

The Board of Trustees has given preliminary consideration to this legislation, and it has been referred to the Committee on Postwar Medical Care for detailed study. That committee has appointed a subcommittee to make the study, and a report by that subcommittee will shortly be made to the full committee.

Additional interest was undoubtedly stimulated in legislation to promote scientific research by the President's reference to the subject in his message to Congress, Sept. 6, 1945. He recommended the establishment of a single federal research agency which would discharge the following functions: (1) promote and support fundamental research and development projects in all matters relating to the defense and security of the nation, (2) promote and support research in the basic sciences and in the social sciences, (3) promote and support research in medicine, public health and allied fields, (4) provide financial assistance in the form of scholarships and grants to

young men and women of proved scientific ability, (5) coordinate and control diverse scientific activities now conducted by the several departments and agencies of the federal government and (6) make fully, freely and publicly available to commerce, industry, agriculture and academic institutions the fruits of research financed by federal funds. These recommendations parallel those contained in the Bush report.

Deferment of Premedical Students.—At the 1944, Chicago, session the attention of the House was called to the then recent action of Selective Service in relation to the deferment of premedical students. A resolution was adopted declaring it to be imperative that immediate action be taken by the President or the Congress to correct the drastic regulations resulting in a restriction in the number of students qualified to enter the courses of medical instruction in approved medical schools. Efforts to obtain a correction of the situation through administrative action proved fruitless and, early this year legislation was introduced by Senator Ellender, Louisiana, S. 637, proposing to authorize the release of persons from active military service, and the deferment of persons from military service in order to aid in making possible the education and training of physicians and dentists to meet essential needs. The bill was referred to the Senate Committee on Military Affairs, and a hearing was scheduled on it May 1. Representatives of the Association appeared in support of the bill, reflecting the position taken by the House at the 1944 session. No further action has been taken on this bill, and it is still pending in committee.

After progress of the legislation had been held up in the Senate, as the result of opposition of the War and Navy Departments and Selective Service, Representative Judd, Minnesota, sponsored a companion bill in the House, H. R. 3350, which was referred to the House Committee on Military Affairs. No action has been taken on the House bill.

Subsequently Senator Downey, California, introduced a resolution in the Senate, S. Res. 134, directing the Committee on Military Affairs to make a complete investigation with respect to the relative needs of the armed forces and the civilian population for the services of medical personnel with a view to ascertaining (1) whether, as a result of developments in the war, or through more efficient utilization of medical personnel, such personnel could be released from the armed forces for civilian service without impairment of the war effort, (2) the speed with which demobilization of medical personnel in the armed forces could be accomplished as the needs of the armed forces diminish and (3) whether any further action was necessary to insure an adequate supply of trained medical personnel to meet the future needs of the armed forces and the civilian population. The Senate Committee on Military Affairs has been exploring the subject further, but, at the date this report is being prepared, no definite procedures have been recommended by the committee to alleviate the situation.

Veterans' Legislation.—With the objective in view of improving the quality of medical care available to veterans, several pending bills propose a reorganization of medical services in the Veterans Administration. No action has been taken on any of them, S. 1079, introduced by Senator Johnson, Colorado, and H. R. 3310, introduced by Representative Rankin, Mississippi, propose to establish a Department or Bureau of Medicine and Surgery in the Veterans Administration. They are pending, respectively, in the Senate Committee on Finance and in the House Committee on World War Veterans' Legislation. H. R. 2253, introduced by Representative Priest, Tennessee, proposes to establish in the Veterans Administration a commissioned service consisting of physicians, surgeons, dietitians, nurses and medical technicians. A bill introduced by Representative Rogers, Massachusetts, H. R. 3317, proposes to establish a Bureau of Medicine and Surgery in the Veterans Administration. Both of the two last mentioned bills are pending in the House Committee on World War Veterans' Legislation.

The House of Representatives has passed a resolution, H. Res. 192, authorizing the Committee on World War Veterans' Legislation, acting as a whole or by subcommittee, to conduct an investigation of the Veterans Administration with a partic-

ular view to determining the efficiency of the administration and operation of Veterans Administration facilities. This investigation has been under way, and a report outlining the results of the investigation is expected to be filed shortly.

Another bill, S. 1187, introduced by Senator White, Maine, for Senator Shipstead, Minnesota, would authorize the appointment of an advisory committee of prominent members of the medical and related professions to advise the President with respect to the formulation of programs to provide medical care and hospitalization for veterans. No action has been taken on this bill. It is pending in the Senate Committee on Finance. A House bill, H. R. 3463, introduced by Representative Voorhis, California, proposes the creation of a National Veterans' Hospital Board with the following duties (a) to advise the Administrator of Veterans' Affairs on all matters pertaining to the hospital or outpatient care of veterans and concerning the appointment of a national executive director for all veterans' hospitals; (b) to conduct a complete survey of all veterans' hospitals and to recommend to the Administrator and the National Executive Director such changes in personnel, such hospital construction and such other action as may be necessary; (c) to consult with the Administrator and the Director on the appointment of chief medical officers for all veterans' hospital units in the United States; (d) to provide adequate arrangements and facilities for continuous research on improved methods in the fields of medicine, psychiatry and all other types of care required by veterans, and (e) to prepare a schedule of salaries, grades and classifications for all types of employees, professional or otherwise, in veterans' hospitals with a view to obtaining competent and qualified personnel. This bill is pending in the House Committee on World War Veterans' Legislation.

Two bills propose a general liberalization and clarification of the veterans law pertaining to hospital treatment, medical care, domiciliary care and related services, S. 1203, introduced by Senator Johnson, Colorado, and H. R. 3522, introduced by Representative Rankin, Mississippi. They are pending, respectively, in the Senate Committee on Finance and the House Committee on World War Veterans' Legislation.

Several bills are pending which would eliminate the financial inability of the veterans to defray expenses of hospital treatment or domiciliary care for nonservice disabilities as a condition precedent to obtaining such treatment or care in a veterans' facility. These bills would do away with what is customarily referred to as a "paupers' oath." As examples of bills of this character are H. R. 1923, introduced by Representative Morrison, Louisiana, H. R. 3332, introduced by Representative Barry, New York, and H. R. 599, introduced by Representative Springer, Indiana.

A bill introduced by Representative Miller, Nebraska, H. R. 3254, would authorize the furnishing of medical and hospital treatment to certain veterans in private facilities. This would be accomplished by defining the term "Veterans Administration facility" as used in the existing law to include any private facility for which the Administrator of Veterans' Affairs may deem it necessary to contract in order to provide medical and hospital treatment (1) in emergency cases; (2) for veterans of any war, in any case in which neither a facility under the exclusive jurisdiction of the Veterans Administration nor a government facility utilized by the Veterans Administration is within a reasonable distance of the place of residence of the veteran; (3) for women veterans of any war, and (4) for veterans of any war in the territories and possessions. A similar bill has been introduced by Representative Sikes, Florida, H. R. 3630. Both are pending in the House Committee on World War Veterans' Legislation. Representative Rogers, Florida, has introduced H. R. 3594, authorizing the Administrator of Veterans' Affairs to reimburse any accredited hospital for hospitalization and treatment, for a period not exceeding ten days, of a veteran of any war, not dishonorably discharged, on certification that the care was of an emergency character and that delay would jeopardize the health or life of the veteran. It is pending in the House Committee on World War Veterans' Legislation.

Three other bills propose to facilitate the receipt of hospital treatment and domiciliary care by former members of the armed forces at institutions nearest their places of residence: S. 755, introduced by Senator Cordon, Oregon, and pending in the Senate Committee on Finance, H. R. 2989, introduced by Representative Huber, Ohio, and H. R. 2921, introduced by Representative Stigler, Oklahoma, both pending in the House Committee on World War Veterans' Legislation.

Another bill, H. R. 1120, introduced by Representative Muddock, Arizona, proposes that for pension purposes any person who served under contract with the War Department as acting assistant or contract surgeon between April 21, 1898 and Feb. 2, 1901 shall be considered to have been in the active military service of the United States for the period of such contract service between those dates.

Pepper Subcommittee on Wartime Health and Education.—This subcommittee of the Senate Committee on Education and Labor is authorized by a Senate resolution to investigate the distribution and utilization of medical personnel, facilities and related health activities and the deficiencies in health and education among persons otherwise fit to be employed to the best advantage in agriculture, industry and other activities so as consistently with the spirit of American institutions and the national emergency best to promote the war and victory. The hearings scheduled so far by the subcommittee have been printed in seven parts. Parts 1 and 4 relate to juvenile delinquency, part 2 to the availability of medical services at Pascagoula, Miss., part 3 to the white collar and fixed income groups in the war economy, parts 5 and 6 to Selective Service objections, medical care in the armed forces and for veterans, and to the availability of medical services and facilities for the civilian population, and part 7 to medical research.

Four interim reports have been submitted to the Senate. Report 1 concerns the white collar and fixed income groups, report 2 juvenile delinquency, report 3 Selective Service statistics and the availability and distribution of medical services and facilities, and report 4 health needs of veterans. Report 3 was published in full in *The Journal*, Jan. 6, 1918 and reprints are available. In this report, after outlining some of the testimony developed at the hearings, the subcommittee included eight recommendations based on its preliminary findings: (1) that federal grants-in-aid to states be authorized for the construction of hospitals, medical centers and health centers, in accordance with integrated state plans approved by the United States Public Health Service; (2) that federal loans and grants be made available to assist in postwar provision of urban sewerage and water facilities, rural sanitation and water facilities, and milk pasteurization plants, in communities or areas where such facilities are lacking or inadequate; (3) that state and local governments be urged to establish full time local public health departments in all communities as soon as the needed personnel become available and that the federal government should increase the amount of its grants to state health departments to the end that complete geographic coverage by full time local health departments may be achieved and that state and local public health programs may be expanded in accordance with needs; (4) that the Army consider the feasibility and advisability of expanding its program for induction and rehabilitation of men rejected because of physical and mental defects; (5) that the medical records of the Selective Service system be preserved and that funds be appropriated for further processing and study of these records; (6) that attention be given to the shortage of personnel with training in psychology and psychiatry and that immediate steps be taken to increase the output of such personnel with a view to providing child guidance and mental hygiene clinics on a wider scale; (7) that federal scholarships or loans be made available to assist qualified students desiring medical and dental education and that increased enrolment of women in medical and dental schools, and premedical and pre-dental courses, be encouraged in every way possible, and (8) that federal funds be made available to states for medical care of all recipients of public assistance and that allotment formulas governing distribution of federal funds to state public assistance programs be made more flexible in order to give more aid to states where needs are greatest.

In the opinion of the committee, a comprehensive health and medical facilities program would pay big dividends in improved national health and physical fitness.

Miscellaneous.—Four bills have been introduced by Representative Price, Florida, proposing, respectively, to establish a United States Military Medical School, a United States Naval Medical School, a United States Navy Training School for Nurses and a United States Army Training School for Nurses, H. R. 3927, H. R. 3924, H. R. 3923 and H. R. 3926. The naval bills are pending in the House Committee on Naval Affairs, the army bills in the House Committee on Military Affairs. Another bill, H. R. 713, introduced by Representative Dickstein, New York, provides that there shall be created in each corps area of the United States a medical training school for the instruction of physicians for the armed forces and the United States Public Health Service. This bill is pending in the House Committee on Military Affairs.

S. J. Res. 89, introduced by Senator Pepper, Florida, for himself and Senator Wagner, New York, Senator Murray, Montana, Senator Capper, Kansas, Senator Bill, Minnesota, and Senator Smith, New Jersey, suggests the convening of an International Health Organization and authorizes the President to take immediate steps toward that end. It is pending in the Senate Committee on Education and Labor.

A bill introduced by Senator Langer, North Dakota, S. 800, proposes to establish a National Infantile Paralysis Clinic at Minneapolis and to appropriate \$20,000,000 for its establishment, maintenance and operation. Another bill, introduced by Representative Stevenson, Wisconsin, contemplates an appropriation of \$500,000,000 to be expended under the direction of the Surgeon General of the United States Public Health Service for research with respect to the cause and cure of cancer and poliomyelitis. It is pending in the House Committee on Interstate and Foreign Commerce.

Two bills propose to establish a United States Commission for the Promotion of Physical Fitness, H. R. 2011, introduced by Representative Weiss, Pennsylvania, and H. R. 2015, introduced by Representative Hartley, New Jersey. Both are pending in the House Committee on Education.

A pending bill, H. R. 1688 introduced by Representative Davis, Tennessee, would authorize the appointment of x-ray technicians as commissioned officers in the Medical Corps of the Army and Navy. Another bill, H. R. 3147, introduced, by request, by Representative Adams, New Hampshire, would authorize the appointment of qualified medical technologists as commissioned officers in the Army of the United States and in the Naval Reserve.

(To be continued)

Coming Medical Meetings

American Medical Association House of Delegates, Chicago, Dec. 3-6
Dr. Olin West, 545 N. Dearborn St., Chicago 10, Secretary.

American Academy of Medicine, Chicago, Dec. 10-11. Dr. Karl B. Eickley,
316 Michigan St., Toledo 5, Ohio.

American Association on Mental Deficiency, Cleveland, Nov. 28-Dec. 1.
Dr. Nell A. Dwyer, Box 51, Mansfield Depot, Conn., Secretary.

American Ophthalmological Society, Hot Springs, Va., Nov. 12-14.
Dr. Walter S. Atkinson, 129 Clinton St., Wittertown, N. Y., Secretary.

American Society of Anesthetists, New York, Dec. 12-13. Dr. McKim L.
Phipps, 745 Fifth Ave., New York 22, Secretary.

American Society of Tropical Medicine, Cincinnati, Nov. 12-15. Dr.
Joseph S. D'Antonio, Tulane Ave., New Orleans 15, Secretary.

Central Society for Clinical Research, Chicago, Nov. 23. Dr. Carl A.
Helford, 602 S. LaSalle Ave., St. Louis 10, Secretary.

Indiana State Medical Association, French Lick, Nov. 6-8. Mr. Thomas A.
Hendricks, 23 E. Ohio St., Indianapolis 4, Secretary.

North Pacific Pediatric Society, Portland, Ore., Dec. 1. Dr. Abels B.
Johnson, Cobb Bldg., Seattle 1, Washington, Secretary.

Puerto Rico Medical Association of San Juan, Dec. 11-16. Dr. Rafael A.
Vila, P. O. Box 3866, San Juan, Secretary.

Southern Medical Association, Cincinnati, Nov. 12-15. Mr. C. P. Loring,
Empire Bldg., Birmingham 3, Alabama, Secretary.

Southern Surgical Association, Hot Springs, Va., Dec. 4-6. Dr. Alfred
Black, Johns Hopkins Hospital, Baltimore 5, Secretary.

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Considerations Governing Location of Physicians in California.—With the approval of the Council of the California Medical Association, the state chairman for the physicians Procurement and Assignment Service, Dr. Harold A. Fletcher, San Francisco, has sent to the chairmen of all county committees on Procurement and Assignment Service and to the secretaries of all county medical societies a proposal for aiding resumption of private practice by physicians who were formerly in California. The policies have been developed on the assumption that every physician in California who served in the military forces deserves protection and help in becoming reestablished in his former location. It assumes further that, "until these men have had an opportunity to return to their former locations, every effort should be made to keep new physicians from locating in those places where their presence might seriously disturb the rehabilitation of the physician not yet released."

The proposal states that

The state chairman of Procurement and Assignment Service still has the responsibility of classifying physicians as essential or nonessential on the advice obtained from his county committees and other sources. The Procurement and Assignment Service has no authority to tell a physician that he can or cannot or must or must not locate anywhere. However, during the emergency, almost all county societies voluntarily passed regulations that, during the emergency, no new physician would be considered eligible to membership in the county society unless he was classified as essential by the Procurement and Assignment Service, as the Procurement and Assignment Service was and is the only agency authorized to so classify physicians as essential or nonessential. The county medical societies are now rightfully taking the stand that the emergency will not be over until there is more or less complete demobilization and there is a more or less complete return of physicians to their former location. These societies are therefore rightfully continuing to consider a physician ineligible who moves into a new location in which he is not classified as essential by Procurement and Assignment Service. This is of greatest importance, as you all know of the forecast of the intended location of thousands of physicians in California who previously practiced in other states.

The following policies should be followed, giving careful consideration to the merits of each case and making these policies flexible and commensurate with the actual needs of the various counties or areas and towns in the counties. The needs of the various locations in the county for medical care should be based temporarily on present needs, assuming that a high percentage of physicians still in the service will have been returned. If there is still a need for more physicians on this basis, room should be made for new physicians, and they should be classified essential if they choose to locate.

1. Physicians returning to former locations are immediately to be considered essential.

2. New physicians coming from previous locations in other states are not to be considered essential except under the necessities of the community as outlined.

3. Physicians formerly practicing in another location in another county in California temporarily must be considered as nonessential to almost the same degree as a physician coming from out of the state. Such physicians should be advised to return to their former locations until the end of the emergency.

4. The group of young physicians who have never practiced anywhere before but who entered the military forces at the end of or during their postgraduate training deserves the greatest care and consideration and help. In many cases these physicians would normally have entered practice in the towns or localities where they lived during their premedical educational years, however, this is naturally very often not the case. Whenever it can be shown that such physicians would normally have located in a particular area on the completion of their education, because of family, social or medical contacts or other reasonably legitimately valid reasons they should be classified as essential and be given every help and consideration in establishing themselves. These young physicians will not in any sense interfere to any great extent with the return to practice of the older men. Exception to this statement may be lack of office space; and, when possible, these young physicians should be taken into association with older men in order to conserve office space. This group as a whole must be considered as the normal replacement of losses from the medical profession, aside from the temporary loss of physicians to the military forces. Preference should naturally be given to young physicians who have lived and been educated in California in their premedical years, regardless of whether they studied medicine in the state or out of the state. However, too much emphasis cannot be given to the importance of helping this group of veterans of this war in becoming established.

It is hoped that county chairmen, as well as secretaries of county societies, will interview personally as many of these returning veterans as possible. A personal interview, frankly stating the aforementioned policies, in almost 100 per cent of the cases will prove that the policies are fair and just, and the physician seeking location will be satisfied that he has been given fair treatment and will express the hope that his own State Procurement and Assignment Service and medical societies are doing as much for their returning veterans as is being done in California. Furthermore, it should be clearly stated that these policies are only for the immediate future and will be abandoned on the termination of the emergency.

GEORGIA

Ninety Years of Age.—Dr. Eugene Rollin Corson, Savannah, recently observed his ninetieth birthday. Dr. Corson graduated at Hahnemann Medical College and Hospital of Philadelphia in 1877.

New Professor of Pediatrics.—Dr. Philip A. Mulherin, Augusta, has been appointed professor and chairman of the department of pediatrics at the University of Georgia School of Medicine, Augusta. He will succeed the late Dr. Claude M. Burpee.

IDAHO

Hospital Under Department of Public Health.—At the request of Governor Charles C. Gossett, Boise, the Idaho Department of Public Health has taken temporary control of the State Hospital, South, at Blackfoot. Dr. Lynn J. Lull, Boise, medical consultant of the state health department, will be acting medical superintendent in place of Dr. George R. Smith, Boise, former director. These changes result from recent investigation by a committee appointed by Governor Gossett following charges of mismanagement against this institution. The governor has stated that, if any criminal offenses have been committed in connection with the management of the institution, the matter will be turned over to the grand jury.

ILLINOIS

Communicable Diseases Control Regulations Revised.—The rules and regulations of the Illinois department of public health for the control of communicable diseases have been revised and made effective as of September 1. The current revision consists in the main of a deletion of obsolete material and an application of those principles of communicable disease control which have been shown by experience to be effective. Favus, pellagra and lymphocytic choriomeningitis were dropped from the list of reportable diseases, while food infections (salmonellosis), toxoplasmosis, meningococcemia, ringworm of the scalp and virus pneumonia were added. Scarlet fever and all other hemolytic streptococcus infections of the upper respiratory tract are now grouped together and subjected to some control measures. A distinction is now made between food infections and food poisoning. The former term refers to those cases of gastroenteritis caused by salmonella and related organisms, while the latter refers to botulinus and staphylococcus food poisonings. The duration of quarantine in scarlet fever and poliomyelitis has been reduced from 21 days to 14 days. Household contacts to cases of meningitis and scarlet fever, may, with permission of the local health authority, be removed from the premises to remain away for the duration of the isolation period and no further restrictions are placed upon their activities. Important changes have been made in the regulations for the control of tuberculosis. It is now required that all open cases of this disease be hospitalized whenever sanatorium facilities are available at public expense. Patients who refuse hospitalization or who leave a sanatorium against medical advice are required to be quarantined. Whenever sanatorium facilities are not available at public expense, the patient must be isolated at home. Considerable revision has been made in the rules governing the conduct of funerals when death has occurred from a communicable disease. Sealed caskets are not required unless the death was from smallpox, cholera, psittacosis or plague. Public funerals may be held regardless of the cause of death, provided only that the funeral is not held from premises wherein are residing contacts who are required to be quarantined. Private services, however, may be held in such instances.

Chicago

Phi Rho Sigma Scholarship Awards.—On October 2 the first Phi Rho Sigma awards were presented at the founders' day convocation of Northwestern University Medical School. The presentation was made by Dr. Howard B. Carroll, president of the medical division, Northwestern University Alumni Association, and president of the Alpha Association of Phi Rho Sigma fraternity. The first award, consisting of \$100 and a certificate, given to the student who has maintained the highest scholastic average during his first three years at Northwestern University Medical School, went to Mr. Edward V. Johnston. The second award, consisting of a framed certificate, offered to the national medical fraternity at the medical school having thirty or more active members enrolled as regular students which has maintained the highest scholastic average during the preceding year, was given to Phi Delta Epsilon. The third award, consisting of \$50 and a certificate given to the man in the winning fraternity who has been chosen by his fraternity as the student to have contributed most toward winning the

award, was presented to Mr. Nelson Lionel Portnoy, who was selected by Phi Delta Epsilon. The awards were established last year to stimulate scholarship in the medical school among the organization groups as well as among the individual students (*THE JOURNAL*, Nov. 18, 1944, p. 770). They were established by Dr. George James Dennis, who wished during his lifetime to remain anonymous as a donor. In accordance with the wish of Dr. Dennis, a tablet executed by Miss Mary M. Webster, sculptress, has been placed in the Archibald Church Library as a reminder of the objective of the awards.

INDIANA

State Medical Meeting.—The ninety-sixth annual session of the Indiana State Medical Association will be held at French Lick, November 6-8, under the presidency of Dr. Neslen K. Forster, Hammond. Included among the speakers will be:

Dr. John Ralston Lindsay, Chicago, Ménière's Syndrome.
Lieut. Col. Truman G. Blocker Jr., M. C., Problems of Maxillofacial Surgery, World War II.
Dr. Loring T. Swain, Boston, Arthritis.

There will be a panel discussion on "The Disabled, the Physician and Employment" with Dr. Carl M. Peterson, Chicago, Secretary, Council on Industrial Health, American Medical Association, Chicago, as the moderator; participants will include:

J. R. Crawley, director, vocational rehabilitation, Indianapolis.
Dr. Earl H. Hare, chief medical officer, Veterans Administration Facility, Indianapolis.
Dr. Harley L. Krieger, medical director, Ford Motor Company, Detroit.
Dr. Harold A. Vonachen, medical director, Caterpillar Tractor Company, Peoria, Ill.
Dr. Eli S. Jones, Hammond.
Dr. Creighton Barker, executive secretary, Connecticut State Medical Society, New Haven.

A war participation luncheon will be addressed by Major Gen. George F. Lull, deputy surgeon general, Washington, D. C., on "Repercussions" and Watson B. Miller, federal security administrator, Washington, "The Medical Profession Today and Tomorrow." The annual banquet will be addressed, among others, by Ralph E. Gates, governor of Indiana, on "Public Health in Indiana." The women's auxiliary to the state medical association will hold its meeting, November 6-7.

KENTUCKY

State Medical Meeting in Lexington.—The ninety-fifth annual meeting of the Kentucky State Medical Association, designated the D. Newton Porter Memorial, will be held at the Phoenix Hotel, Lexington, October 29-31, under the presidency of Dr. Oscar O. Miller, Louisville. Among the out of state speakers will be:

Dr. Vilray P. Blair, St. Louis, Fundamentals of Plastic Surgery.
Col. Howard Rush, M. C., Washington, D. C., Rehabilitation: A Medical Challenge.
Major William McDonald Ewing, M. C., Recent Trends in Orthopedic Surgery.
Major Emory L. Shidlett, M. C., X-Ray Diagnosis in Reconstruction Surgery of the Wounded Abdomen.

The oration in medicine will be delivered by Dr. David G. Miller Jr., Morgantown, on "The Future of the Rural Practitioner" and the oration in surgery by Dr. Richard T. Hudson, Louisville, on "Bachelache." At a public meeting Tuesday evening, October 30, Dr. J. Watts Stovall, Grayson, will deliver the President's Address on "The Country Doctor, Past and Present." Other speakers will be Dr. Morris Fishbein, Editor of *The Journal*, "Medicine in the Postwar World"; Dr. Andrew S. Brunk, Detroit, "Prepayment Medical Service," and Mr. Thomas A. Hendricks, Secretary of the Council on Medical Service and Public Relations, American Medical Association, on activities of the council.

MASSACHUSETTS

Stephen Rushmore Retired as Dean of Middlesex.—Dr. Stephen Rushmore was recently retired as dean of Middlesex University School of Medicine, Waltham. The action was taken by vote of the trustees of the university and was worded to take effect immediately, according to the *New England Journal of Medicine* September 27. Dr. Rushmore will devote himself to the practice of obstetrics and gynecology.

Prize Subscription Goes to Tufts Student.—The annual prize subscription offered by the *New England Journal of Medicine* for the best undergraduate contribution to the *Tufts Medical Journal* has been awarded to Eugene G. LaForet for his paper on "Medical Aspects of Submarine Warfare," which appeared in the March 1945 issue. The paper "Myasthenia

Gravis: A Complete Review," by Albert M. Starr and Banice M. Webber received honorable mention; it appeared in the January 1945 issue. According to custom, these students will be given a two year and a one year subscription to the *New England Journal of Medicine*, respectively.

MINNESOTA

Dr. Ridgway Said to Be State's Oldest Practicing Physician.—Dr. Alfred M. Ridgway, Amundale, is credited by *Minnesota Medicine* with being the oldest practicing physician in the state both in age and in term of service. Dr. Ridgway was born in 1862, graduated at the University of Minnesota Medical School, Minneapolis, in 1890 and has been practicing fifty-five years. *Minnesota Medicine* said that Dr. Ridgway not only keeps regular office hours but takes night calls.

Dr. Pearce Named Tuberculosis Control Officer.—Dr. Naboth O. Pearce, Minneapolis, has been appointed tuberculosis control officer in the Minnesota Department of Health to direct a statewide tuberculosis program. The work, which will be financed by a federal grant of \$100,000, will be supplemental to activities now carried on by Dr. Walter J. Mareley, Minneapolis, in the division of preventable diseases, by the local health departments and the Christmas Seal organizations. The objective of the program is to discover incipient cases of tuberculosis.

MISSISSIPPI

Twenty-Five Years as Health Director.—Dr. Rosier D. Dedwylder, Cleveland, recently completed twenty-five years of service as director of the Bolivar County health department, with headquarters in Cleveland. Dr. Dedwylder gave up his private practice in 1912 to work with the state board of health and the Rockefeller Foundation in a study of hookworm in the south. He subsequently carried out investigation of malaria and malaria control. On July 1, 1920, Cleveland was selected for the first full time health department in the state and one of the first in the South and Dr. Dedwylder was named health director.

MISSOURI

John Auer Lecture.—Dr. Walter C. Alvarez, Rochester, Minn., delivered the second annual John Auer Lecture at the St. Louis University auditorium, October 10, on "Helpful Hints for the Understanding of Puzzling Pains." The lectureship is an annual function of St. Louis University School of Medicine and is sponsored by Lambda chapter of Phi Beta Pi medical fraternity. It was instituted in July 1944 in honor of Dr. John Auer, professor of pharmacology at St. Louis University.

Gross Prize Goes to Robert Elman.—The Philadelphia Academy of Surgery announces that the Samuel D. Gross prize for 1945 in the amount of \$1,500 has been awarded to Dr. Robert Elman, St. Louis, for his essay entitled "Parenteral Alimentation in Surgery with Special Reference to Protein and Amino Acids." Others who submitted essays may arrange for their return, if desired, by communicating with Dr. Calvin M. Smyth Jr., Methodist Hospital, Broad and Wolf streets, Philadelphia 48.

NEW JERSEY

Personal.—Dr. Joseph P. Holt, Louisville, associate professor of physiology at the University of Louisville School of Medicine, has been appointed director of research in the medical department of the Standard Oil Company, New Jersey, according to *Science*, September 28. —Edward A. Stiles, secretary of the National Rehabilitation Association, who was director of vocational rehabilitation in Vermont for nearly eight years, has been appointed program director of the state rehabilitation commission. Mr. Stiles succeeds Joseph Spitz, who resigned recently.

Remington Medal Goes to Pharmaceutical Chemist.—Joseph Rosin, pharmaceutical chemist of Plainfield, has been announced as the recipient of the 1945 Remington medal of the New York Branch of the American Pharmaceutical Association. In naming Mr. Rosin to receive the medal, the committee on award cited his work as "foremost American authority on chemical reagents" and stated that the Pharmacopoeia and National Formulary, the two official books of standards for medicines in this country, "are today more indebted to Mr. Rosin for the excellent quality of their chemical standards than to any other person."

ALASKA

Members of Alaska Board of Health.—Four residents of Alaska, one from each judicial division, were Dr. Dwight L. Cramer, Ketchikan; George Preston Sr., Fairbanks; Mrs. Katherine Kehoe, Nome, and Rev. Rolland Armstrong, Anchorage.

GENERAL

Report of Infantile Paralysis Foundation.—The annual report for the year ended May 31, 1945 covering the activities of the National Foundation for Infantile Paralysis has recently been released. The report, among other things, discusses the disbursements of the foundation to embrace research projects to various institutions.

Sociologic Foundations of the Psychiatric Disorders of Childhood.—The Twelfth Institute on the Exceptional Child of the Child Research Clinic of the Woods Schools, Langhorne, Pa., November 2, will be devoted to the theme "Sociological Foundations of the Psychiatric Disorders of Childhood." The institute will be held at the Amphitheatre, Duke University, Durham, N. C., in collaboration with the Duke University School of Medicine.

New Periodical on Obstetrics and Gynecology.—Dr. Emil Novak and Dr. Nicholson J. Eastman, Baltimore, the editors, announce the publication of a new abstract periodical, *Obstetrical and Gynecological Survey*. It will cover the entire medical periodical literature, both foreign and domestic, and will appear bimonthly beginning in February 1946. Nine hundred pages per year will be published and the subscription price will be \$9. The Williams and Wilkins Company, Baltimore, will be the publishers.

Association for the Advancement of Science.—The American Association for the Advancement of Science will hold a meeting in St. Louis, March 27-30. This will be the first peacetime and really full-scale meeting of the association since the Philadelphia meeting in December 1940. It is expected that researches that have been accumulating during five years of war will now be made generally public. The advances in laboratory equipment and supplies and new books on science will be presented at a science exhibit.

Journal Changes Hands.—The *Nervous Child* has been bought by its founder and editor in chief, Ernest Harms, from its previous owner, Grune & Stratton Medical Publishers of New York. The *Nervous Child* will be produced from now on by a new publishing house, Child Care Publications, New York, which has been created for this purpose. The same publishing house will start to issue during 1946 another periodical entitled the *Journal of Child Psychiatry*, devoted to unsolicited contributions in the field of mental disease in children.

Hospital Commission Stimulates Survey Action.—There are now twenty states and the District of Columbia which have under way surveys of their hospital facilities as a result of activities of the Commission on Hospital Care, a nongovernment public service committee to study hospital surveys in the United States, it was announced October 8. Surveys are now in progress in Washington, Idaho, Montana, Wyoming, North Dakota, Minnesota, Iowa, Kansas, Oklahoma, Wisconsin, Illinois, Michigan, Indiana, Tennessee, Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, New Jersey and the District of Columbia. Surveys have not yet started but have been officially authorized in Oregon, New Mexico, Arkansas, Florida, North Carolina, Virginia, West Virginia, Delaware and New York, and surveys are being planned in California, Nevada, Arizona, Colorado, South Dakota, Nebraska, Texas, Missouri, Louisiana, Mississippi, Ohio, Pennsylvania, Kentucky, South Carolina and Connecticut. Surveys have been completed in Utah, Alabama, Georgia and Maryland.

Palestine to Have Medical School.—The Hebrew University and Hadassah, the Women's Zionist Organization of America, will build a nonsectarian medical school on Mount Scopus in Jerusalem. It is planned to raise four million dollars in a two year countrywide campaign to begin immediately. Campaign headquarters have been opened at 16 East 48th Street, New York. The goal of the financial drive will not only meet the cost of construction, equipment and five year maintenance of the school, which will be known as the Hebrew University-Hadassah Medical School, but will provide an additional 100 beds in the Rothschild-Hadassah Hospital, a part of the Hadassah-University Medical Center. The increase will bring the total bed strength of the hospital to

400. Dr. Jonas S. Friedenwald, associate professor of ophthalmology, Johns Hopkins University School of Medicine, Baltimore, is chairman of a Hadassah sponsored American committee on medical education. The plans call for the construction of three main buildings, with provision for future expansion, and the use for certain departments of the existing Nathan Ratnoff Building, which now houses the postgraduate medical school of the university. In addition, the present departments and laboratories of the university and medical center, many of which will be enlarged, will become a part of the proposed school. The new buildings will be erected a short distance from the university and close to the medical center and will be of an architectural design harmonious with the modern style of the group of medical center structures. It is hoped soon to appoint an administrative officer of the medical school and give him the opportunity to study administrative methods in selected medical schools in the United States and England.

Prevalence of Poliomyelitis.—Reports of cases of poliomyelitis for the week ended October 20 have been received from the division of public health methods, U. S. Public Health Service, as follows:

FOREIGN

Work Continues on Paderewski Memorial.—The Paderewski Memorial Hospital, located at the University of Edinburgh, Scotland, will continue attached to the university for another year, according to the *Polish Review*, August 23. The hospital was organized at the University of Edinburgh by the Polish School of Medicine and has cared for 62,392 outpatients and 30,000 inpatients since its founding in 1941. There are twenty-three professors and lecturers and twenty-four doctors attached to the Polish Medical Center in Edinburgh. Dr. Anthony T. A. Jurasz is director of the hospital. Credit for the start of a library at the hospital is given to Mrs. Herbert M. Woollen, Indianapolis, head of the Indiana section of the Paderewski Testimonial Fund. The national group set up a committee which has been active in collecting and financing the purchase of books for the library. The hospital was named for Ignace Jan Paderewski, who was active in the welfare of his people. On his death in June 1941 national feeling indicated that the best memorial to his memory would be a much needed hospital for Polish forces stationed in the British Isles outside of Edinburgh. The hospital, made possible by donations from the Paderewski Testimonial Fund, was opened Oct. 17, 1941 (THE JOURNAL, Jan. 3, 1942, p. 61).

CORRECTION

"Air Embolism Following Insufflation During Pregnancy."—In the article by Herbert S. Breyfogle (THE JOURNAL, September 29) appears a statement to the effect that the manufacturer of silver picrate does not publish a warning against the danger of insufflation of air through the vagina in pregnancy. Mr. Ambrose Hunsberger Jr., representative for Wyeth, Inc., points out that all of the literature issued by that company does contain such warnings.

Postgraduate Surgical Teaching at the Royal College of Surgeons

The Royal College of Surgeons maintains a library, museum and laboratories for the use of medical graduates from all parts of the world. These facilities are available to fellows and members of the college by right, but they have also been made open, on suitable introduction, to medical graduates who are not members or fellows. They are also open to undergraduates, and a large number of students have used the library during the war, though unfortunately the museum specimens were not available because of the danger of bombing. It is hoped that they will soon be on exhibition again. The college also arranges short courses of lectures on the contents of the museum—the Arnott Demonstrations of Anatomy by Professor Cave and the Erasmus Wilson Demonstrations in Pathology by pathologists and surgeons appointed each year. In addition, the Arris and Gale and the Hunterian lectures provide opportunities for the presentation of original work in anatomy, physiology, pathology and surgery.

In recent years the professors of the college have given an increasing number of lectures, and it has now been arranged that two regular courses shall be given each year on anatomy, pathology and applied physiology by Professors Wood Jones, A. J. E. Cave, John Beattie and R. A. Willis. These courses will deal with the subjects of the primary examination for the fellowship. They are not designed to provide complete and comprehensive instruction in these subjects but to deal with such fundamental aspects as will be selected from time to time. They must not be regarded as classes specially arranged for the examination but are so planned as to be helpful to candidates and also to surgeons by dealing with recent advances in these subjects and their practical application. At present these courses are open to all medical graduates without fees, but later fees may be charged to those who are not members or fellows of the college.

Another innovation is the decision of the council to provide instruction in surgery by courses of lectures designed to assist those engaged in specialist work and those who are preparing for the final examination for the fellowship of the college. These lectures will be free to fellows and members of the college, but others will be required to pay a small fee. The college also awards prizes for meritorious work as well as many fellowships for those who desire to engage in practical work in the museum and laboratories.

Better Health Provisions for Miners

Addressing the South Wales miners' leaders, Mr. Shinwell, minister of fuel and power, said that he was determined that the health of miners should be better safeguarded. His parliamentary secretary would devote special attention to health and safety measures. He had heard from the miners' leaders that young men fought shy of the pits because of the incidence of industrial disease, particularly silicosis, from which 5,810 miners had been certified as suffering during the war. There would have to be more provision for rehabilitating disabled men, including training for other occupations, so that young men would be assured that they would not become unemployable if they incurred any disease. He intended to see that no miner who might be disabled as the result of his work was cast on the scrap heap but that he was trained for other useful employment.

PARIS

(From Our Regular Correspondent)

Sept. 26, 1945.

The Responsibility of the Physician

For the first time the Paris court of appeals has delivered a verdict concerning the physician's responsibility in a blood transfusion case. A physician (the director of a blood transfusion center) who attended a patient with a gastric ulcer was obliged to administer a transfusion of 350 cc. of blood, which was given by one of the regular blood donors assigned to his center. On the same day the blood donor was submitted to the periodic examination, which in this particular center takes place twice every quarter instead of once as officially prescribed. The examination showed a positive Bordet Wassermann reaction, known on the day after the transfusion. Another clinical examination, which followed at once, disclosed the existence of a syphilitic chancre on the blood donor's person.

The arguments of the law court were as follows: Taking into consideration that under the present state of science it is impossible for the physician to be absolutely sure that the donors' blood is pure because syphilis involves a period of incubation, called the "silent period," and taking into consideration that the contract between the patient and the physician obliges the latter to give his patient scrupulous care in accordance with the state of knowledge of science, that Dr. X is still less to be excused for not having taken . . . the necessary precautions, since his patient has expressed his fear of being infected; also that an authoritative section of the medical profession insists on a closer checking of blood donors. Since the customary methods of control are quite insufficient to guarantee the safety of the patient, the physician is fined 200,000 francs.

Miscellaneous

A congress of the French Association for Progress of Sciences will take place October 20 to 26 in Paris for the first time since 1940. Papers will be read on the avitaminoses in deportees' camps by Charles Riehet, on the amazing bacillary variability and its significance from the point of view of general biology by Boyin, Institut Pasteur member of the Académie de médecine, and on radiology in France from 1940 to 1945 by Lacassagne of the Collège de France.

The ninth French congress of gynecology will be held on October 6, 7 and 8, at which uterine fibromas will be discussed.

Marriages

OLIVER HALTOM GRAVES, Jackson, Tenn., to Miss Bettie Frances Gray of Stamford, Texas, at Carlisle Barracks, Pa., August 11.

WALTER GAMWELL WATSON, Trenton, S. C., to Miss Audrey Lynette Rasmussen of Swainsboro in Silver Run, Md., August 29.

PRESTON CALVIN STRINGFIELD JR., Dallas, Texas, to Miss Billie Vaughn Johnson of North Wilkesboro, N. C., September 15.

VERLYNNE VINCENT VOLIN, Lennox, S. D., to Miss Susanne Cronin of Windsor, Ont., Canada, in Detroit, September 8.

CHARLES TEAR FRIED, Long Island City, N. Y., to Dr. Ethel Lieberman of Edmonton, Alta., Canada, recently.

JAMES CARRINGTON FRANCIS, Anniston, Ala., to Miss Virginia Lee Eskridge of Birmingham, July 22.

HAROLD D. WALTZ, Sandusky, Ohio, to First Lieut. Marie Mayse in Reims, France, August 11.

LINCOLN GODFREY JR., Merion, Pa., to Miss Patricia Agnes Greylin in St. Davids, September 1.

CARL N. GRESSLER, McMinnville, Tenn., to Miss Margaret North of Nashville, September 18.

EDWARD SCOTT GOODWIN, Albany, N. Y., to Mrs. Caroline Peltz Kerr of Selkirk, August 4.

Deaths

Robert Levy * Denver; Bellevue Hospital Medical College, New York, 1884; born in Hamilton, Ont., Canada, May 30, 1864; professor of otolaryngology emeritus at the University of Colorado School of Medicine; at various times on the faculty and secretary of the Gross Medical College and the Denver and Gross College of Medicine; chairman of the Section on Laryngology, Otology and Rhinology of the American Medical Association, 1912-1913; past president of the Colorado State Medical Society, Denver County Medical Society and the American Laryngological, Rhinological and Otolological Society; member of the American Academy of Ophthalmology and Otolaryngology and the American Laryngological Association; fellow of the American College of Surgeons; one of the founders and three times president of the Denver Clinical and Pathological Society, becoming president emeritus; served as a major in the medical corps of the U. S. Army during World War I; major, Officers Medical Reserve Corps, April 1919; specialist certified by the American Board of Otolaryngology; otolaryngologist to the Colorado General Hospital, St. Joseph's Hospital, Denver General Hospital, St. Luke's Hospital and Children's Hospital; otolaryngologist to the National Jewish Hospital, where he had been a member and chairman of the medical advisory board for many years; on April 4, 1934, in recognition of his completion of fifty years in the practice of medicine, his oil portrait was presented to the Medical Society of the City and County of Denver; died July 1, aged 81, of cerebral hemorrhage.

Alexander A. Conrad * Crete, Neb.; John A. Creighton Medical College, Omaha, 1915; born at Crete on April 6, 1890; secretary and past president of the Saline County Medical Society; past vice president of the Nebraska State Medical Association; past president of the Seventh Councilor District of the state medical association, serving as councilor for that district; secretary of the board of education for many years and member at the time of his death; for twenty-six years city physician; served as chairman of the Procurement and Assignment Service for the state, as a member of the Saline County insular board, local surgeon for the Burlington Railroad and for many years physician for Doane College; on the associate staffs of the Bryan Memorial Hospital, St. Elizabeth Hospital and the Lincoln General Hospital, Lincoln, where he died July 9, aged 55, of carcinoma of the pancreas.

James Alexander Waddell * Charlottesville, Va.; University of Virginia Department of Medicine, Charlottesville, 1911; professor of pharmacology, materia medica and toxicology at his alma mater, where he had been secretary of the faculty of medicine from 1915 to 1943, premedical adviser from 1918 to 1924 and chairman of the committee on admissions from 1920 to 1930; secretary of the Charlottesville-University-Albemarle Board of Health from 1923 to 1930; high school principal, 1901-1902; affiliated with the blind department of the Virginia School for Deaf and Blind from 1902 to 1907; epidemiologist, State Department of Health during the summer in 1909 and from 1912 to 1915; member of the Virginia Academy of Toxicology, American Association for the Advancement of Science and the Society for Pharmacology and Experimental Therapeutics; died June 8, aged 67.

G. Graham Watts, San Antonio, Texas; Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, Germany, 1881; honorary member of the State Medical Association of Texas; member of the American Medical Association; served as an ambulance driver in the Franco-Prussian War in 1870 and as an assistant surgeon at Fort Sam Houston during the Spanish-American War; during World War I served in the surgeon's office at Fort Sam Houston; affiliated with the Santa Rosa Infirmary and the Medical and Surgical Hospital; had a part in the establishment in 1895 of the San Antonio Infirmary and in 1903 of the Physicians and Surgeons Hospital, where he died July 11, aged 92, of uremia and generalized arteriosclerosis.

Gilbert Leslie Gosslee, Moorhead, Minn.; Minneapolis College of Physicians and Surgeons, medical department of Hamline University, 1903; a captain in the medical corps of the U. S. Army during World War I; for ten years resident director of the State Teachers College; eighth councilor district representative on the state procurement and assignment board; county health officer; served as city health officer; on the staff of St. John's Hospital, Fargo, N. D., where he died July 15, aged 68, of cerebral hemorrhage and myocardial degeneration.

William P. Addison, Shreveport, La.; Memphis (Tenn.) Hospital Medical College, 1899; died July 16, aged 73, of coronary occlusion.

Annie Mary Slate Anderson, Los Gatos, Calif.; M.B., University of London Faculty of Medicine, London, England, in 1892 and M.D. in 1894; died May 28, aged 78.

Charles Edward Anderson, Los Angeles; University of the South Medical Department, Sewanee, Tenn., 1900; died July 11, aged 69, of coronary occlusion.

William Lamar Atkins * Shreveport, La.; University of Louisville (Ky.) School of Medicine, 1916; fellow of the American College of Surgeons; on the staffs of the Shreveport Charity Hospital and the T. E. Schumpert Memorial and North Louisiana sanitariums; died June 16, aged 52, of coronary occlusion.

Horace James Beel, Grand Rapids, Mich.; University of Buffalo School of Medicine, 1909; past president of the Kent County Medical Society; served overseas during World War I; formerly senior attending surgeon at the Butterworth Hospital and visiting surgeon at the Blodgett Memorial and St. Mary's hospitals; died July 14, aged 58, of cerebral hemorrhage and hypertensive heart disease.

Chester Bradley Bliss * Sandusky, Ohio; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896; fellow of the American College of Surgeons; past president of the Ohio Public Health Association; served as president of the staff at the Good Samaritan Hospital; died July 10, aged 71, of myocarditis.

William Charles Brandon, Garfield, Wash.; Vanderbilt University School of Medicine, Nashville, Tenn., 1892; University of Nashville (Tenn.) Medical Department, 1902; served during the Spanish-American War and World War I; died in Colfax, July 4, aged 78, of carcinoma of the bladder.

Hymie Henry Brenner, Minneapolis; University of Wisconsin Medical School, Minneapolis, 1943; an intern at the Mount Sinai Hospital in Cleveland; served a residency at the Minneapolis General Hospital; drowned at Detroit Lakes, July 5, aged 35, when his boat capsized.

Baumont Brown, Sacramento, Calif.; College of Physicians and Surgeons of San Francisco, 1904; for many years on the staff of the Washoe County General Hospital in Reno, Nev.; died July 2, aged 68, of myocarditis due to arteriosclerosis.

Francis Aloysius Campana, Union City, N. J.; Fordham University School of Medicine, New York, 1918; died in St. Francis Hospital, Jersey City, July 6, aged 49, of chronic glomerulonephritis.

William Patrick Cannon, Somonauk, Ill.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905; served overseas during World War I; district surgeon for the Illinois Central Railroad; died in St. Mary's Hospital, Kankakee, August 6, aged 64.

Covert Ballejo Cooper, Arlington, Texas; Medical Department of Tulane University of Louisiana, New Orleans, 1911; member of the American Medical Association; had been affiliated with the North American Aviation plant and on the staff of the Methodist Hospital in Dallas; died June 2, aged 56, of coronary thrombosis.

Fred Fay Dexter, Springfield, Mass.; Harvard Medical School, Boston, 1904; member of the American Medical Association; formerly secretary of the Eastern Hampden Medical Association; served as medical examiner for the Monarch Life Insurance Company; died July 10, aged 66, of heart disease.

Henry August Dirschedl, Pottsville, Pa.; Medico-Chirurgical College of Philadelphia, 1910; member of the American Medical Association; served as a member and president of the city board of health; for many years medical inspector of the public school system; formerly county prison physician and coroner; for many years on the staffs of the Good Samaritan, Pottsville and Warne hospitals; died July 14, aged 71, of coronary thrombosis.

Howard L. Dumble, Hood River, Ore.; National University Medical Department, Washington, D. C., 1893; died in the Hood River Hospital July 6, aged 85, of cerebral hemorrhage and heart disease.

John L. Dunkel, Fremont, Ind.; Medical College of Ohio, Cincinnati, 1896; died in the Leila Y. Post Montgomery Hospital, Battle Creek, Mich., July 10, aged 80, of heart disease.

Rubie Epstein * Trenton, N. J.; Hahnemann Medical College and Hospital of Philadelphia, 1924; on the staff of the McKinley Memorial Hospital, where he died July 28, aged 47, of acute cardiac failure and coronary occlusion.

Andrew Joseph Erickson, Chicago; Chicago Medical School, 1921; on the staffs of the Belmont and Walther Memorial hospitals; died in St. Anne's Hospital July 29, aged 58, of injuries received in an automobile accident.

William Bingham Ewing, West Grove, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1900; owner of the West Grove Hospital, where he died July 31, aged 69, of coronary thrombosis.

Albert Samuel Fay Ⓢ Schenectady, N. Y.; University of Vermont College of Medicine, Burlington, 1896; past president of the Schenectady County Medical Society; consulting physician to the Ellis Hospital; died July 2, aged 72, of carcinoma.

John Richard Frazier, Fort Worth, Texas; Jefferson Medical College of Philadelphia, 1884; served on the Selective Service Board during World War I; past president of the old Fort Worth Medical Society, predecessor of the present Tarrant County Medical Society, serving as president of the latter organization in 1907; first company physician for Swift and Company; died in the Pennsylvania Avenue Hospital June 11, aged 83, of myocarditis and pulmonary edema.

Neil Alexander Gates Ⓢ Ann Arbor, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; died in St. Joseph's Mercy Hospital July 16, aged 72, of primary carcinoma of the liver.

Charles Patterson Geddes, New Castle, Pa.; Cleveland University of Medicine and Surgery, 1897; died in the Torrance (Pa.) State Hospital May 26, aged 76, of chronic myocardial disease and arteriosclerosis.

Chesley T. J. Giles, Greenville, S. C.; University of Georgia Medical Department, Augusta, 1899; member of the American Medical Association; honorary member of the South Carolina Medical Association; on the staff of the Greenville General Hospital, where he died July 5, aged 76, of coronary thrombosis.

Horace Mark Hall, Los Angeles; Chicago Medical College, 1883; died July 9, aged 91, of angina pectoris.

William John Hammond Ⓢ East Walpole, Mass.; Harvard Medical School, Boston, 1899; specialist certified by the American Board of Psychiatry and Neurology, Inc.; member of the American Psychiatric Association, New England Society of Psychiatry and the Association for Research in Nervous and Mental Disease; founder and superintendent of the Westwood Lodge, Westwood; died July 4, aged 75, of pneumonia.

David M. Hestand, Houston, Texas; Baylor University College of Medicine, Dallas, 1914; died July 1, aged 58, of carcinoma of the lung with metastasis to the liver.

Foster Cannon Howard, Baltimore; Maryland Medical College, Baltimore, 1912; served during World War I and in the regular U. S. Army; died June 19, aged 56, of coronary heart disease.

Jesse Headen Inman Ⓢ Bakersfield, Calif.; University of California Medical School, San Francisco, 1929; member of the board of directors and past president of the Kern County Medical Society; member of the American Society of Clinical Pathologists and the American Heart Association; member of the board of the Kern County Tuberculosis Association; on the staffs of the Kern General and Mercy hospitals; died July 15, aged 43, of carcinoma of the descending colon.

U. H. Johnson, Port Richmond, Va.; Medical College of Virginia, Richmond, 1905; died in the Johnston-Willis Hospital, Richmond, July 11, aged 68, of cerebral hemorrhage.

John Paul Keith, Louisville, Ky.; Hospital College of Medicine, Louisville, 1904; member of the Radiological Society of North America, Inc.; on the staff of the Baptist Hospital; died on his farm near Anchorage, June 30, aged 66, of coronary occlusion.

Isaac Celsus Kiser, Piqua, Ohio; Ohio Medical University Columbus, 1897; member of the American Medical Association; also a graduate in pharmacy; served as a member of the state legislature; on the staff of the Memorial Hospital; died June 26, aged 71, of heart disease.

Felix J. Krych, Forty Fort, Pa.; Atlantic Medical College, Baltimore, 1909; member of the American Medical Association; on the staff of the Wyoming Valley Homeopathic Hospital, Wilkes-Barre, where he died June 26, aged 62, of bronchopneumonia.

William Everett Lloyd Ⓢ Columbus, Ohio; Ohio Medical University, Columbus, 1905; in 1917 joined the medical department of the state industrial commission as claims examiner; member of the Columbus Academy of Medicine; died in the University Hospital July 12, aged 67, of chronic myelogenous leukemia.

Howard Kimball Longshore, Glenside, Pa.; Maryland Medical College, Baltimore, 1911; served on the staff of the Hospital of the Woman's Medical College of Philadelphia; died at his summer home in Thousand Islands, N. Y., July 12, aged 62, of coronary thrombosis.

Julius D. Love Ⓢ Philadelphia; Medico-Chirurgical College of Philadelphia, 1893; on the staff of the Mount Sinai Hospital; died July 4, aged 86, of cardiovascular renal disease.

Fay Melville Marsh Ⓢ Ionia, Mich.; Saginaw (Mich.) Valley Medical College, 1900; also a graduate in pharmacy; past president of the Ionia-Montcalm Counties Medical Society; city physician and health officer; for many years physician for the Ionia County Home; on the staff of the Ionia County Memorial Hospital; director of the State Savings Bank of Ionia; died July 2, aged 69, of coronary thrombosis.

Bertrand Frank Marshall, Westbrook, Maine; Dartmouth Medical School, Hanover, N. H., 1888; member of the American Medical Association; honorary member of the Maine Medical Association, which in 1938 presented him with its fifty year service medal; served as city physician, school physician and police commissioner; died June 22, aged 78.

William Thomas McKinney, Louisville, Ky.; Vanderbilt University School of Medicine, Nashville, Tenn., 1899; medical director of the Kentucky Home Mutual Life Insurance Company; died in St. Joseph Infirmary June 29, aged 77, of endocarditis.

Edgar Paul Murdock Ⓢ Guadalupe, Calif.; Bennett Medical College, Chicago, 1909; on the staff of Our Lady of Perpetual Help Hospital in Santa Maria, where he died June 24, aged 59, of cardiorenal vascular disease.

John Christopher O'Day, Honolulu, Hawaii; National Normal University College of Medicine, Lebanon, Ohio, 1896; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900; fellow of the American College of Surgeons; author of two books; died July 2, aged 78, of arteriosclerotic heart disease.

John Howard Prill, Chetek, Wis.; Milwaukee Medical College, 1910; for many years affiliated with various Veterans Administration facilities; died June 15, aged 58, of angina pectoris.

Samuel A. Reynolds, Vashti, Va.; Medical College of Virginia, Richmond, 1887; member of the American Medical Association; died July 8, aged 80, of heart disease.

Amos Elmer Robinson, Leachville, Ark.; University of Tennessee College of Medicine, Memphis, 1915; member of the American Medical Association; past president of the Mississippi County Medical Society; served in the medical corps of the U. S. Army overseas during World War I; on the staff of the Walls Hospital, Blytheville; died in St. Bernard's Hospital, Jonesboro, July 5, aged 57, of heart disease.

John Frederick Stageman, Council Bluffs, Iowa; John A. Creighton Medical College, Omaha, 1903; on the associate staff of the Jennie Edmundson Hospital and the Mercy Hospital, where he died June 20, aged 69, of cerebral hemorrhage.

Dewey Sutton, San Angelo, Texas; University of Louisville (Ky.) Medical Department, 1910; member of the American Medical Association; served in the medical corps of the U. S. Army during World War I; died June 2, aged 61, of cerebral hemorrhage.

Cassell Clark Tucker Ⓢ Greencastle, Ind.; Harvard Medical School, Boston, 1915; awarded British Military Cross for service overseas during World War I; vice president and director of the First-Citizens Bank and Trust Company; on the staff of the Putnam County Hospital, where he died June 6, aged 54, of coronary thrombosis.

John James Tully, Stockton, Calif.; Cooper Medical College, San Francisco, 1886; died in the Stanford Lane Hospital, San Francisco, June 4, aged 82, of arteriosclerotic myocardial failure.

Vivian H. Vandeventer Ⓢ Ishpeming, Mich.; College of Physicians and Surgeons, Baltimore, 1896; served as president and vice president of the Upper Peninsula Medical Society; fellow of the American College of Surgeons; for many years health officer of Ishpeming and chief of the staff of the Ishpeming Hospital; died July 3, aged 73, of cerebral hemorrhage.

Hedwig Maria Ziskoven, Los Angeles; Rheinische Friedrich-Wilhelms-Universität Medizinische Fakultät, Bonn, Prussia, Germany, 1921; member of the American Medical Association; on the staff of the California Hospital; died July 10, aged 50, of tuberculosis.

Correspondence

DERMATOPHYTOSIS AND ONYCHOMYCOSIS

To the Editor:—In reply to Dr. K. P. A. Taylor's criticism (THE JOURNAL, July 7, p. 750) of an article by me on dermatophytosis and onychomycosis (THE JOURNAL, May 12, p. 77), the paper dealt primarily with the cutaneous manifestations of the fungi causing dermatophytosis and onychomycosis rather than with methods of treatment. Only the most important and proved methods of treatment were noted.

Permanent ablation of fungous infected toe nails outlined by Dr. Taylor is a radical measure. The absence of finger nails would subject the patient to lifelong embarrassment. Elimination of the fungi in the nails would not necessarily cure the infection. When toe nails are infected, especially with *Trichophyton purpureum*, there is usually a concurrent infection of the toes and soles. The refugees that he mentioned as being unable to enter the country because of chronic onychomycosis of the *T. purpureum* type were probably still harboring *T. purpureum* in the toes and soles even after ablation of the nails.

I still believe that the more conservative method is preferable, as I mentioned in my paper, though it requires more careful therapy and is time consuming. Of nine toe nails infected with *T. purpureum* in 1 patient within the last year, I have cured seven by this method. First all infected portions of the nail plate are painstakingly removed by clipping and paring. This is followed by the application of salicylic acid to the nail and nail bed, repeating the procedure until a new nail is firmly attached to the nail bed. Strong fungicides are applied periodically until a normal nail has grown in. This treatment may take six months or longer. Concomitant infection of the skin is treated at the same time.

Dr. Louis Tobin of the New York Skin and Cancer Unit has been successful in treating mycotic nails by simple evulsion. The after-treatment includes the application of strong fungicides. He reports cures in 80 per cent of these cases.

Another method mentioned by Dr. Taylor, that of freezing the affected skin areas with ethyl chloride, was tried at the New York Skin and Cancer Unit in a series of cases this year. Our conclusions were the same as those of Drs. J. H. Lewis and W. J. Morginson (Treatment of Trichophytosis with Ethyl Chloride, *Arch. Dermat. & Syph.* 50:243 [Oct.] 1944), who found that "recurrences are experienced in practically all instances within ten days."

Treatment of dermatophytosis and onychomycosis must vary according to the infecting organism and the cutaneous manifestations. Any infection due to *T. purpureum* is a tedious and a difficult one to cure. It is hoped that in the future more effective fungicides may be found to clear these fungous infections more quickly and completely.

ROYAL M. MONTGOMERY, M.D., New York.

RHUS DERMATITIS

To the Editor:—I wish to substantiate the statement of Francis E. Park (THE JOURNAL, August 18, p. 1185) that steaming hot water is an effective treatment for rhus dermatitis.

Thirty years ago while on a horseback trip through the Feather River Canyon I became disabled with poison oak. At an Indian camp the Indians treated me with steaming hot water from a mineral spring. I enthusiastically carried a bottle of the water away with me but later found steaming tap water to be equally effective. Some of my friends have substituted live coals held close or infra-red from bathroom heaters or cigarettes.

The rationale of the treatment may possibly be explained by a detoxification or oxidation of the phenols or catechols in the oils or oleoresins embedded in the skin.

The water should be about 130 F. or slightly over and the application should produce a mild first degree burn. Moderately hot water seems to be useless or merely to aggravate the condition. The treatment is rather heroic, and only small areas can be treated at a time. A sponge stick is useful in applying the heat. I have never used the treatment during the bullous stage of a severe case.

It is doubtful whether this homely treatment will prove popular, owing to the attending discomfort; but it is hoped that the possibility of oxidation or detoxification of poison oak and poison ivy by intense heat or enzymes such as tyrosinase will be subject to further investigation by those best qualified to undertake it.

ROBERT A. POWERS, M.D., Palo Alto, Calif.

TESTS FOR INFECTIOUS HEPATITIS

To the Editor:—In regard to the methylene blue test used in infectious hepatitis, as reported in recent issues of THE JOURNAL, I have made some of the following observations:

One patient with early clinical jaundice of the infectious hepatitis type did not have a positive methylene blue test (5 drops of methylene blue with a still green coloration of the urine).

Patients recovering from infectious hepatitis who showed a negative methylene blue test still had bilirubin in the urine.

Patients not suffering from infectious hepatitis will show a green coloration of the urine with as high as 3 drops of methylene blue before the blue coloration is noted. Normally one does not have bilirubin in the urine.

I have made serial dilutions of an atabrine solution (yellow) and have demonstrated a progressive increase in the number of drops of methylene blue needed to change the solution from green to blue, going even beyond the 5 drop "positive" reaction, depending on how yellow the solution is made.

I believe that the so-called "positive methylene blue test" of the urine as used in infectious hepatitis cases is equivocal.

O. W. HAFFKE, Captain, M. C., A. U. S.

Medical Examinations and Licensure

COMING EXAMINATIONS AND MEETINGS

BOARDS OF MEDICAL EXAMINERS BOARDS OF EXAMINERS IN THE BASIC SCIENCES

Examinations of the boards of medical examiners and boards of examiners in the basic sciences were published in THE JOURNAL, Oct. 6, page 478.

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II, Nov. 12-14, Part III, New York City, Oct. 15-17; Boston, Oct. 16-17. Exec. Sec., Mr. E. S. Elwood, 225 S. 15th Street, Philadelphia.

EXAMINING BOARDS IN SPECIALTIES

AMERICAN BOARD OF ANESTHESIOLOGY: *Written*. Various centers, Jan. 18. Final date for filing application is Oct. 20. *Oral*. Various centers, Oct. 1946. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York 24.

AMERICAN BOARD OF DERMATOLOGY & SYPHILOLOGY: *Written*. Group B, April 22. *Oral*. Group A and B, June 6-8. Final date for filing application is March 1. Sec., Dr. George M. Lewis, 66 E. 66th St., New York 21.

AMERICAN BOARD OF NEUROLOGICAL SURGERY: *Oral*. Chicago, May 27. Final date for filing application is Feb. 1. Sec., Dr. P. C. Bucy, 912 S. Wood St., Chicago 12.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *Written*. Part I, Various centers, Feb. 2. Final date for filing application is Nov. 1. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh 6.

AMERICAN BOARD OF OPHTHALMOLOGY: Chicago, Jan. 18-22 and Los Angeles, Jan. 28-Feb. 1. Sec., Dr. S. Judd Beach, 56 Ivie Rd., Cape Cottage, Me.

AMERICAN BOARD OF OTOLARYNGOLOGY: Spring 1946. Sec., Dr. Dean M. Lierle, University Hospital, Iowa City, Ia.

AMERICAN BOARD OF PEDIATRICS: *Written*. Locally, Oct. 19. *Oral*. Atlantic City, Dec. 7-8. Sec., Dr. C. A. Aldrich, 115½ First Ave., S.W., Rochester, Minn.

AMERICAN BOARD OF SURGERY: *Written*. Part I, Spring 1946. Final date for filing application is Dec. 1. Sec., Dr. J. Stewart Rodman, 225 South 15th St., Philadelphia.

AMERICAN BOARD OF UROLOGY: *Written*. Various centers, Dec. 9. *Oral*. Chicago, February 1946. Sec., Dr. Gilbert J. Thomas, 1409 Willow St., Minneapolis 4.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1935 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but can be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Mental Hygiene in Public Health Program: Its Implications. C. F. McClintic.—p. 708.

Complement Fixation Test in Rickettsial Diseases.—

Bengtson says that since 1941 there has been an opportunity to make use of the complement fixation test for rickettsial diseases on a large scale at the National Institute of Health. Over 10,000 tests have been made. The complement fixation test was found to furnish evidence of rickettsial infection earlier than the Weil-Felix test in 23.9 per cent of the human serums tested. From an epidemiologic standpoint the complement fixation test is superior to the Weil-Felix test because a positive complement reaction persists longer than does a positive Weil-Felix reaction. Low titers are significant in the complement fixation test, as indicated by negative results on a number of nonrickettsial and normal serums.

- Allergy to Chemicals in Flour: Case of Dermatitis Due to Benzoic Acid. K. A. Baird.—p. 195.

Nonantigenic Property of Beeswax.—

Gay states that no pollen could be identified in crude or filtered beeswax by microscopic examination. Beeswax cannot be kept in solution for intramuscular injection in a concentration greater than 4 per cent wax by weight in peanut oil. In this mixture there is no tendency for the wax to separate from the oil. No reaction occurred by scratch or intracutaneous tests with 4 per cent beeswax-peanut oil mixture in any of the patients who were tested, even though they had clinical hay fever or asthma due to one or more varieties of pollens. The control solutions gave typical reactions. The results of the studies indicate that beeswax, combined with peanut oil, because of its nonantigenic

character, should be an ideal medium for delaying the absorption of penicillin when administered by subcutaneous or intramuscular methods.

Carbon Tetrachloride Poisoning.—

Dillenbergh and Thompson report observations on 20 patients with carbon tetrachloride poisoning, who used the solvent in a confined compartment of a submarine without adequate ventilation. Only 2 men worked with the solvent; the rest inhaled the fumes by being in or near the compartment over a period of two days. The initial symptoms in all 20 cases were headache, malaise, backache, anorexia, nausea and vomiting. Albuminuria was present in 11 cases on admission. These 11 patients were admitted to the dispensary for both the albuminuria and the severe gastrointestinal symptoms. The other 9 were treated aboard the submarine tender and recovered without complications in four days. Kidney damage was present in 11 cases on admission to the dispensary. This was manifested by slight albuminuria to anuria, which persisted for several days. The 4 severe cases presented a typical toxic nephrotic syndrome, as evidenced by puffiness and swelling of the soft tissues of the face, hands and feet. One patient developed acute pulmonary edema while apparently on the road to recovery. This was a late complication occurring nine days after exposure and terminated fatally despite all treatment. There were positive roentgen findings in the lungs of the 4 severe cases. The histories and roentgenograms of the 4 critically ill patients are presented with the necropsy and microscopic findings in the fatal case. Microscopic examination revealed severe damage to the liver, kidney and adrenal. Patients were treated symptomatically along with intravenous dextrose and calcium gluconate. Carbon tetrachloride is dangerous because it can be absorbed through the skin, inhaled and ingested. It is essential that instructions be given regarding its use.

- Eclampsia E M Chapman —p 194.

Senile Psychosis and Pellagra.—Meyersburg says that several patients with psychoses of the senile type have been observed to improve after therapy with niacin, thiamine, riboflavin and substances rich in the vitamin B complex. Review of their records has shown 2 with atypical pellagra. In the first patient, a woman aged 55, the late manifestations were like those of a vascular disturbance, although the earlier ones were neurasthenic. The latter disturbances, the memory defects and the confabulatory episodes resembled the Korsakoff syndrome, which may occur in either the senile psychoses or in pellagra. The episodes of stupor were similar to those described in pellagrins. The skin lesions were those of riboflavin deficiency, and the mucosal alterations were the combined effect of several deficiencies. The response to treatment puts this case definitely in the pellagra group. The effect of nutritional inadequacy in a patient with a subclinical encephalopathy of the combined senile and vascular type was illustrated by the second patient, a man aged 78. The reestablishment of adequate neurologic function and the concurrent disappearance of the somatic signs of deficiency under therapy indicate that the neuropsychiatric dysfunction was related to biochemical imbalance. The neuropsychiatric manifestations of pellagra usually appear after dermal, oral or gastrointestinal manifestations have developed. In a small proportion of cases, however, neuropsychiatric signs alone are manifest. The senile pellagrous type of encephalopathy may respond well to treatment with crystalline vitamin B products or with natural vitamin B concentrates. The recognition of this group of cases may permit effective therapy. The maintenance of an optimal dietary by the normal aged person as well as by the senile invalid is of primary importance.

Pediculosis Corporis and Leg Ulcers.—Morris stresses that multiple ulcers of the legs are frequently due to infestation of the clothing with body lice. Search for such parasites should be made in all suspicious cases. In a large hospital clinic ulcers of the leg due to pediculosis corporis rank second in frequency only to the so-called stasis (varicose) ulcers. Such lesions respond well to eradication of the body lice followed by the local application on alternate days of a 1 per cent aqueous solution of gentian violet and 2 per cent allantoin in a water soluble emulsion base.

Osteomyelitis of Skull.—According to Schnitker and McCarthy, osteomyelitis of the frontal bone, secondary to frontal sinusitis, is one of the most fatal of surgical diseases. The primary infection, acute sinusitis, is fairly common but the complication of frontal osteomyelitis is relatively uncommon. In the fulminating type manifested by pitting doughy edema of the forehead it is imperative to do wide radical removal of the diseased osteomyelitic bone. Sulfonamide drugs have been advocated in addition to operation, but these drugs have their limitations. Penicillin has revolutionized the treatment. It is an excellent bacteriostatic agent; it overcomes the infection rapidly and limits its spread, permitting early operation with primary closure of the wound and rapid recovery. Until recently the inverted T incision was used with open packing of the wound and subsequent deforming scar of the forehead. With the use of penicillin a coronal incision is preferable, giving a more adequate exposure and allowing the removal of the diseased bone in one piece, so avoiding a deforming scar of the frontal scalp. When healing is complete and all infection has disappeared, repair of the underlying bone defect with insertion of a tantalum plate is carried out easily. The restoration of the smooth contour of the forehead is accomplished. The authors report 3 cases.

Book Notices

The Extremities. By Daniel P. Quiring, Ph.D., Beatrice A. Boyle, Erna L. Boroush and Bernardine Lufkin. Paper. Price, \$2.50. Pp. 55, with 106 illustrations. Cleveland, Ohio: Cleveland Clinic Foundation, 1945.

This is a carefully worked out and precisely illustrated textbook which succinctly describes the points of anatomic and surgical interest in the musculature of the extremities. The bulk of the book consists of line drawings illustrating the origin, insertion and motor point and the nervous and arterial supply of each muscle individually. Careful attention is paid to the site of entrance into the muscle of its arterial and nervous supply. The exact relationship of the muscle to the skeleton is well brought out. In the caption for each illustration the aforementioned items are enumerated and reference is made to the main functions of the muscle. The remaining five illustrations point out in a superficial manner the salient points in the skeleton and in the vascular and nervous trees of the extremities.

The excellent line drawings are clear and unembellished by extraneous detail, although a little shading in the correct locations would have made some of the illustrations easier to assimilate rapidly.

A valuable addition to the caption of each drawing is a list of page references for each muscle in Gray's Anatomy and in Cunningham's Anatomy. Page numbers of illustrations, which are particularly clear, are included in these references.

The well catalogued brevity of this book renders it most useful for the student of anatomy, of physical therapy and of extremity surgery.

Psychology in General Practice. Edited by Alan Moncrieff, M.D., F.R.C.P. The Practitioner Handbooks. Published on behalf of The Practitioner. Cloth. Price, 12s. 6d. Pp. 199. London: Eyre and Spottiswoode, Ltd., 1945.

This compact volume, eleventh in the Practitioner Handbook series, performs just what it promises. In seventeen brief chapters contributed by specialists, the mental aspects of disease are presented simply and sympathetically to the general practitioner. He is encouraged by the common sense statements to be alert to, sympathetic with and interested in the psychologic factors which contribute to nearly all symptom pictures and are of prime importance in a large fraction of the cases reaching this office. As Culpin says, an eminent psychiatrist wrote that he saw more psychologic cases in general practice than he did later when specializing in the subject. Further, the practitioner is urged to try his hand at simple psychotherapy and to seek expert help freely and is given the needed criteria on which to make his judgments.

General statements on classification of mental disease, case taking, differential diagnosis and therapy are followed by sections on the depressive, anxiety and compulsive states, hysteria, visceral neuroses, problems of childhood, mental defect, delinquency and sex problems. The chapters on the practitioner's attitude (Culpin), anxiety states (Ling) and obsessions (Boyle) are especially vivid as presented. It is a healthy sign that a chapter on psychiatric social work is included; one on admission to and discharge from mental hospitals, being directed to the English situation—as is the whole volume—will be of less interest to American physicians.

The influence of the war is shown in the treatment of the subject matter, the illustrative cases and the poor quality of paper in the volume. The approach to the subject avoids esoteric and controversial matters and, while the psychoanalytic point of view is well represented, all views are given attention. Each author has made a visible effort to write for the general practitioner, and most have happily succeeded. It is high time these matters received the earnest attention of the nonspecialist and that Culpin's introductory statement be made obsolete: "After lecturing to medical practitioners, I have often been approached and told 'I never come across the symptoms you have been talking about,' and the statement has often been accompanied by a manner—perhaps tinged with only slightly masked incredulity—that has tempted me to reply 'Quite so; and you never will.'"

Food Regulation and Compliance. Volume I. By Arthur D. Herrick. Cloth. Price, \$10. Pp. 646. New York: Revere Publishing Company, 1944.

This volume is written by an experienced food and drug consultant on problems relating to the laws governing food manufacture and marketing. The laws themselves are not reproduced but their application to all aspects of food labeling is discussed in detail. Following a brief historical sketch on the evolution of food regulation, twenty chapters are devoted to problems of food labeling. Under each subject the regulations are outlined and their meaning is interpreted. Subsequently all possible ways in which intentional or unintentional violation might be made are discussed. The frequent use of sample statements or situations serves to make all points clear and the information practical. The sections dealing with food standards and their violation are particularly informative. The style of presentation is simple, straightforward and nontechnical. Frequent quotations from governmental trade correspondence and court decisions add specificity. This book can be recommended as exceedingly valuable to any one interested in or confronted with problems of food labeling.

Curso de malariología, División de malariología, Ministerio de sanidad y asistencia social, Dirección de salubridad pública, Venezuela. In Two Volumes. Boards. No pagination, with illustrations. Maracay, Atagua, Venezuela, 1944.

This is an outline, in Spanish, of a course in malariology given in Maracay under the direction of Dr. Arnoldo Gabaldon, chief of the Division of Malariology, Venezuela, from Oct. 2 to Dec. 1, 1944 to twenty-six students from Bolivia, Colombia, Ecuador, Peru and Venezuela and one from the United States. The first forty-nine pages consist simply of a schedule by hours of the lectures and class exercises. There follow in the first volume introductory, hematologic and entomologic sections, presented largely in outline, doubtless conforming to lectures attended by the students. The second volume covers in the same way various aspects of epidemiology, treatment and prophylaxis. The two volumes no doubt were useful to the students concerned and would be of interest to any agency planning a similar course. But they do not constitute a textbook, manual or reference book in the usual sense.

Tierexperimentelle Untersuchungen über die Wirkung langdauernder Foellikelhormonapplikation und die hormonale Tumorentstehung. Von Dr. Hubert von Wattenwyl, Oberarzt am Frauenspital Basel. Cloth. Price, 24 Swiss francs. Pp. 235, with illustrations. Basel: Benno Schwabe & Co., 1944.

In this monograph are reported the author's experiments on the effects of long continued administration of natural and synthetic estrogens to guinea pigs and other rodents. His experiences confirm the work of others, particularly that of Lipschutz of Chile, in that he was able to produce extragenital fibromas in the domestic guinea pig by the implantation of pellets of natural estrogens as well as diethylstilbestrol. He observed a transient loss of hair in some of his animals. Others failed to gain weight at the same rate as the controls. Noteworthy local and systemic effects of long continued estrogenic stimulation were not obvious. The experiments were not numerous but they were carefully planned and executed. There is a complete bibliography.

An Introduction to the Medical Sciences for Medical Record Librarians. By J. H. Neese, M.D., and F. H. Swett, Ph.D. Edited by F. H. Swett, Professor of Anatomy, Duke University School of Medicine, Durham, N. C. Cloth. Price, \$2.50. Pp. 223. Durham, N. C.: Duke University Press, 1944.

The major portion of this book is devoted to discussions of anatomy, physiology and some of the pathologic processes of the various systems of the body. The discussion follows the classification of the Standard Nomenclature of Disease. The remainder treats of such subjects as vitamins, anesthesia, medical prefixes and suffixes, drugs and abbreviations. There is a glossary. The volume is designed for the medical record librarian. The teaching schedule as outlined seems to be a worthy introduction to the medical sciences and to hospital orientation. More comprehensive sources of information should be included for such a course, however.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

LATE EFFECTS OF FREEZING

To the Editor:—A patient who froze both feet ten years ago has suffered from severe burning sensations in the feet both day and night for the past five years. It is more severe in hot weather. His feet never perspire. He wears shoes which are freely ventilated. Are there any similar cases on record? Has any remedy for relief been successful?

Alexander Kremers, M.D., Kaukauna, Wis.

ANSWER.—Frost bite, like "trench foot" and "immersion foot," often produces fibrosis of the subcutaneous tissues. When the thermal injury is severe the scarring involves the more superficial muscles, blood vessels and nerves. In these circumstances there are likely to be permanent contractures of the toes, weakness of the supporting structures and atrophy of the skin. Loss of sweating in a patient like this suggests permanent damage to the sympathetic nerves to the sweat glands. The burning pain, which is the chief complaint, is probably caused by incomplete recovery of the cutaneous sensory nerves. Hyper-sensitive skin and burning pain in cases of partial nerve damage are most difficult lesions to treat. No satisfactory form of medication has been found for treating these injuries due to cold in this war. In the occasional case complicated by a poor peripheral circulation, sympathectomy may be of help by increasing the blood flow. In a patient who froze his feet ten years ago and has suffered severely for only the past five years, if he is past middle age the condition may be secondary to superimposed occlusive vascular disease. Diagnostic procaine block of the lumbar sympathetic ganglions should certainly be tried, to be followed by ganglionectomy if there is a favorable response.

AMINOPHYLLINE IN HEART DISEASE

To the Editor:—Please indicate the use of aminophylline by injection for uncomplicated hypertensive cardiovascular disease. Is its use by injection once or twice a week to be recommended in persons over 60 years of age as a routine procedure?

M.D., New York.

ANSWER.—Aminophylline has been used extensively in the treatment of disease of the coronary arteries complicating hypertension, but its value as an agent for dilating the coronary arteries has been questioned. This subject was well reviewed by N. H. Boyer in *THE JOURNAL*, May 29, 1943, page 306. Its routine use for persons over 60 years of age is not recommended.

SACCHARIN IN DIABETES

To the Editor:—Is it permissible for one suffering from diabetes mellitus to use saccharin? Will saccharin raise the blood sugar level or cause sugar to appear in the urine?

D. R. Martin, M.D., Carrollton, Ill.

ANSWER.—It is permissible for a diabetic patient to use saccharin. It will not raise the blood sugar level or cause sugar to appear in the urine. It will not hurt the heart or the eyes of a diabetic patient.

DIMETHYL AND DIBUTYL PHTHALATE AND GLYCEROL TRIACETATE

To the Editor:—Are there any ill effects from inhaling dimethyl phthalate, dibutyl phthalate and glycerol triacetate or getting these on the hands? A patient complains chiefly of dyspnea and a feeling that he is going to faint.

Harry M. Salzer, M.D., Cincinnati.

ANSWER.—Information as to toxic properties of the phthalates is scanty. More is known about di-(2-ethylhexyl) phthalate and dibutyl phthalate than about dimethyl phthalate. $(C_6H_4(COOCH_3)_2)$, which contains methyl alcohol 33 per cent and phthalic anhydride 76.17 per cent. The dibutyl form is believed to be much more toxic than the diethyl, and the dimethyl is probably not less toxic than the diethyl. Shaffer, Carpenter and Smyth (*J. Indust. Hyg. & Toxicol.* 27:130 [May] 1945) discuss the toxicity of diethylhexyl phthalate, chiefly with reference to animals and limited to acute and subacute poisoning. Two adult human subjects swallowed single

doses of 10 Gm. and 5 Gm. respectively. In the first instance this ingestion was accompanied by mild gastric disturbances and moderate catharsis. Some of the phthalate was recovered in the urine within twenty-four hours. This substance, while not acting as a skin irritant, apparently is freely absorbed through the skin, which thus may be a prime port of entry, since the high boiling point (295 C.) of this substance is not conducive to free evaporation and inhalation. The lethal dose by skin absorption in rabbits after skin application and ingestion appears to be near 25 cc. per kilogram of body weight. All rats inhaling a mist of dibutyl phthalate died after fifteen minutes' exposure; all rats inhaling a mist of diethyl (diethylhexyl) phthalate died after four hours. Diethyl phthalate applied directly to the eyes did not produce ill effects. These authors conclude that diethyl phthalate is a chemical of low toxicity and that such damage as arises is probably attributable to the alkyl rather than to the phthalate portion.

Glycerol triacetate is believed to constitute a severe skin irritant, since it contains approximately 83 per cent of acetic acid.

UTERINE BLEEDING FOLLOWING MENOPAUSE

To the Editor:—A woman aged 57 passed the menopause at 49; she had no particular difficulty at that time. In May of 1941 a thorough checkup at a clinic indicated she had a chronic cholecystitis with stones, angina pectoris, toxic labyrinthitis, obesity and chronic nervous exhaustion. The electrocardiogram showed some evidence of cardiac damage, apparently on a sclerotic basis. The nervous exhaustion could be explained by the fact that she holds a demanding job and has an invalid husband who is dependent on her, not only for support, but for much of his physical care. By the summer of 1944 her heart condition appeared to have improved a good deal, and, because she was beginning to have more and more digestive trouble which was apparently due to the gallstones, cholecystectomy was performed. A short time following the removal of the gallbladder and while she was still in bed, she had a small amount of vaginal bleeding. In a few days she began to spot again, and this continued until March, with only brief periods of one to three days without any discharge. In March a diagnostic curettage revealed a menopausal type of endometrium with hemorrhage. Pelvic findings are within normal limits on bimanual examination. Repeated examinations during the time of flow have always shown that the flow is from the cervix and that the vaginal mucosa is of normal appearance. Six weeks after the curettage she spotted lightly for two or three days, and six weeks later this was repeated. She has no discomfort at this time, with the exception of a mild bearing down sensation in the pelvis. Most of the time she feels quite well, although she has a mild arthritis which involves particularly the hands and the knees. What are the chances of a cancer developing in the uterus at this time or later?

M.D., Nebraska.

ANSWER.—The diagnosis of uterine bleeding in a woman of 57 who had her menopause eight years previously is cancer until this condition is ruled out. True, in this case cancer has not been found on bimanual examination, on inspection of the cervix or on endometrial curettage. Occasionally a thorough curettage of the endometrium may be performed and a carcinoma overlooked. Such a cancer, a small one, may exist in the cervical canal and not be detected unless the curet is used carefully and systematically on the endocervix as well as on the endometrium. A small carcinoma in the corpus may also be missed on curettage. Furthermore, the patient may have a cancer in the oviducts or in one or both ovaries. In such instances the endometrium would be normal. In the presence of a granulosa cell tumor of the ovary the endometrium is usually hyperplastic.

The occurrence of the bleeding following shortly after the cholecystectomy is almost certainly accidental. This woman should have further surgery. If the operator is experienced in vaginal work he may do a vaginal hysterectomy with removal of both tubes and ovaries. If vaginal surgery cannot be done for one reason or another, a laparotomy should be performed and the uterus and adnexa removed. Even though the ovaries may not be felt on bimanual examination, one or both may contain a neoplastic growth.

SIGNIFICANCE OF LOW BASAL METABOLIC RATE

To the Editor:—With reference to the answer to Dr. Bakke's question in the Aug. 18, 1945 issue of *The Journal*, page 1194, I think the following additional comments might be in order. In so-called pituitary deficiency, in which the basal metabolic rate is depressed, it is frequently found that the administration of thyroid extract is dangerous, since severe and at times critical attacks of hypoglycemia may be produced. Such cases respond well to testosterone or adrenal cortex extract. It is likely that in such cases the low basal metabolic rate is due not to hypothyroidism but such cases the low basal metabolic rate is due not to hypothyroidism but rather to a low fundamental metabolism of the tissues themselves. It is for that reason, and also because the glycogen storage in the liver is low, that thyroid extract must be given with extreme caution. A determination of the blood cholesterol and of the sugar tolerance curve is helpful in deciding whether it is safe and desirable to administer thyroid extract. William Wolf, M.D., New York.
